have selected. It is remarkable, however, the amount of bleeding some patients will sustain without manifesting any prejudicial influence.

Acute Rheumatism with Pericardial Complication — Large Bloodletting—Almost Immediate Recovery.—Caron Emile, aged 17, admitted into La Charité, under the care of M. Bouillaud, February 25th, 1852; a lad of a spare frame, and somewhat delicate appearance. About five days previous to admission was seized with symptoms of rheumatism, affecting first the feet, and afterwards ascending to the knees and other larger joints, which became hot, swollen, and painful, to a degree completely to disable him. Accompanying these local symptoms, there were an accelerated pulse, a hot skin, in fact, considerable febrile disturbance, with a pericardial *frottement*, audible over the base of the heart. On the evening of his entrance into the hospital, he was bled to fourteen ounces. The blood presented a highly inflammatory character, the clot being buffed, cupped, and strongly contracted.

Feb. 26th.—At the ordinary visit of the morning, the patient's symptoms were scarcely altered from those he presented on admission. He was accordingly ordered venesection to fifteen ounces immediately, and to be repeated during the day, with cupping to the same extent over the region of the heart, and a dose of opium at night. The inflammatory appearance of the blood diminished at each bleeding, the clot of that drawn by the last venesection being scattered and not retracted, but remaining of a bright red colour.

27th.—Patient very much relieved, almost entirely free from pain, and bearing no remaining evidence of any pericardial affection.

March 1st.—May be looked upon as convalescent as regards his rheumatism, having no pain or swelling of the joints, or febrile disturbance, but presenting a pallid aspect, with an evidence of much muscular debility. His condition continuing favourable till March 9th, he was discharged, bearing no remaining perceptible traces of his previous rheumatic affection.

Acute Articular Rheumatism—Free Bloodletting—Rapid Relief, succeeded by Great Prostration, Erysipelas, Gangrene of the Lower Extremity, and Death.—Louise Martin, aged 15, a fine, healthy, robust, florid-faced, full-grown girl, occupied as a seamstress, and received into M. Bouillaud's wards at La Charité, February 8th, 1852, labouring under an attack of acute arthritic rheumatism, with which she had been seized a few days previously. The symptoms she presented were of a severe and sthenic nature, and, independently of the general febrile disturbance, which was considerable, were located principally in the larger joints, the shoulders and knees, but more especially the left knee, which was hot, exquisitely sensitive, and much more swollen than the other. Concomitant with these general and arthritic symptoms, there was a pericardial affection revealed by a *bruit de frottement* audible over the base of the heart. The treatment consisted in venesection to fifteen ounces, repeated three times during the first twenty-four hours of her admission, combined with the application of twenty leeches to the left knee, and the administration of a dose of the extract of opium at night. A blister was afterwards applied to the knee, and succeeded in a few days by compression by means of a bandage, and the opium at night was continued in conjunction with an edulcorated tisane during the day. Under these measures our patient sensibly and rapidly improved; her febrile symptoms subsided, her pulse diminished in fulness and frequency, her pain and suffering abated, her *bruit de frottement péricardique* vanished, and her knee became reduced to its ordinary dimensions. On February 18th, in fact, ten days after her admission, it was remarked that she might be regarded as in a perfectly convalescent condition; and her case was cited as a good illustration of the efficacy of free bloodletting in acute rheumatism, and its superiority even over all other modes of treatment. Notwithstanding these favourable indications, however, there were also others bearing an aspect of a less propitious nature, for she remained weak and prostrate, and her cheeks had entirely lost that healthy blush which originally and naturally belonged to them.

Feb. 23rd.—Was considerably agitated and excited this morning, and complained of tenderness of the lower part of her back, on which she constantly lay, and on which there was to be seen a slight superficial redness over the sacral region, presenting the appearance of a commencing bed-sore.

25th.—A most marked change during the last forty-eight hours, from a condition regarded as one of almost convalescence to one of as equally almost entire hopelessness. Pulse quick (over 120), small, and disappearing under the slightest pressure; face extremely pallid, and presenting also a somewhat icteroid tinge; severe and frequent rigors; extreme sensibility to the slightest movement; extensive superficial redness, with subjacent swelling, reaching from the sacrum over the gluteal region and outer side of left thigh nearly to the knee, the bandage surrounding which was ordered to be removed.

26th.—Pulse 150, feeble and fluttering; tongue moist and white; mind inclined to ramble; erysipelas extending, accompanied with much swelling, and presenting a colour of a dark, unhealthy aspect.

27th.—Features sharp, and stamped with a cadaverous aspect; the whole of the left lower extremity, but most especially the thigh, much swollen, mottled of a dark blue colour, and emitting an offensive and decidedly gangrenous odour; abdomen tympanitic; occasional delirium. 8 p.m.—Expired. No autopsy permitted by the friends.

Remarks.—Of the two preceding cases, the first appears an unquestionable illustration of an ordinarily severe attack of acute rheumatism, complicated with a distinct pericardial affection, cut short in the course of a few hours by the free abstraction of blood, combined only with the administration of opium at night, which cannot be regarded as playing more than the part of an adjunct, for the purpose of relieving pain and procuring sleep. This case is not a mere casual or exceptional one, but, on the contrary, belongs to a general rule observed in M. Bouillaud's wards, that under the heroic use of bloodletting. Bloodletting resorted to immediately, and employed freely, boldly, and without hesitation, acute rheumatism seldom resists beyond a few days; and, if not then entirely subdued, is most materially mitigated or relieved. The second case, which was characterised by its extreme severity on admission, is also an example of the rapid relief accruing from free bloodletting in this disease; but it unhappily does not stop short here, for no unbiassed or unprejudiced mind can for a moment doubt that the anæmiated and debilitated condition of the patient, resulting from the treatment adopted, mainly contributed to her untimely end. Acute rheumatism is not in itself a fatal disease, neither can we regard it in this instance, except in its course of antecedence or priority in the sequence of events, as having been the cause of the termination which resulted.

SCIENTIFIC LECTURES.

HUNTERIAN LECTURES ON THE ANATOMY OF INVERTEBRATE ANIMALS.

BY RICHARD OWEN, F.R.S.,
Hunterian Professor to the College.

THIS EVENING, APRIL 24.—Lecture XVIII.—*Insecta.* Principles on which the Articulata with jointed limbs and tracheæ are classified: primary division according to the number of the segments of the chitinous skeleton: subdivision of the Myriapoda and Hexapoda. Composition of the skeleton and its appendages; orders of Hexapod Insects according to the structure of the wings. Modifications of the nervous system: organs of sense; antennæ, palpi. Structure of the mouth in Haustellate and Mandibulate Insects. Examples of the manifold modifications of the alimentary canal. Salivary, biliary, and urinary glands. Circulating and respiratory systems.

TUESDAY, APRIL 27.—Lecture XIX.—*Generation of Insects.* All Insects diœcious. Generative system of the Myriapoda. Vesicular testes and ladder-like anastomoses of the two vasa deferentia in the Iulidæ: advanced position of termination of sperm-ducts. Male organs of Centipede. The single ovarium with single oviduct in Centipedes, and the two oviducts in Iulus. Spermathecæ and colleteria. Hexapod larvæ and their metamorphoses by multiplication of segments and joints. Business of generation in Hexapod or "True" Insects committed to four kinds of individuals,—Males, Females, Neuters or nursing-females, and procreant virgin larvæ. General structure of the male organs. Analogy of the testes in their numerous and various forms and occasional bright colours to flowers. Monogamy or Polygamy in Insects governed by the structure of the intromittent organ. External outlets of sperm-ducts remote from that of the vesiculæ seminales and from the penis in the Dragon-fly. General characters of the female organs: exceptional simplicity of those of the procreant larval Aphides. Modifications of the vulva, and its appendages the ovipositor and sting. Various uses and applications of the colleterial secretion. External sexual characters. Abnormal Hermaphroditism. Development of the ova, and their various forms and appendages. Cocoons and other nidi. Oviparous, larviparous and pupiparous insects. Striking evidence of design in the instincts of oviposition. Development of the embryo: various grades of this at which it quits the ovum. The metamorphoses of insects: the larva, pupa, chrysalis, or aurelia. The imago. True character of these defined stages and varieties. Metamorphosis a course of development alike in its essentials, with its stages varied as to time and place: all insects at first vermiform: larval types of Entozoa, Earth-worms, Nereids, Myriapods, and Crabs. Metamorphosis and development of organs in Lepidoptera.

THURSDAY, APRIL 29.—Lecture XX.—*Arachnida.* Characters of the class and of its chief divisions. The Cephalothorax and abdomen. Nature of the four pairs of legs. Maxillæ and modified antennæ and nervous system. Ocelli. Narrow œsophagus and sacculated stomach; intestine; cæcum, biliary and urinary glands. Relation of gastric cæca to long endurance of abstinence. Heart: vascular and respiratory systems. Secreting organs of the prism and of the web. Male organs of Spiders: termination of sperm-ducts remotely from the vesiculæ seminales: transfer of these sacs and the intromittent organ to the end of the cephalic palpi. Tubular testes of Scorpions and their anastomoses: short sperm-duct and long cæcal sperm-sacs: papilliform penis. Pectinate appendages. Long ovaria and short oviducts of Spiders: spermatheca and modi-

fications of vulva. Female organs of Scorpions: developmental pouches of the viviparous species. Coitus and oviposition of Spiders: their strong maternal instincts: silken and other nests. Development of germ and embryo: early manifestation of the class-character.

Saturday, May 1.—Lecture XXI.—*Mollusca Acephala.* Characters of the Tunicata, Brachiopoda and Lamellibranchiata; their organisation respectively exemplified by that of the Ascidian, the Terebratula and the Oyster. Structure and relations of the bivalve shell. Muscular system. Nervous system and organs of sense. Stomach and triturating style. Vascular and respiratory systems. Inhalant and exhalant syphons. Modifications of these and of the shell-valves in the Ship-borer (Teredo.) Relations of the compound Ascidians to Polypes, and their propagation by gemmation as well as ova. Generative organs of dicœcious Ascidiæ. Development and metamorphosis of Ascidians. "Alternate generation" of viviparous Salpæ. Dicœcious condition the rule in lamellibranchiate bivalves. Male and female organs bulky but simple: short sperm-duct of males, short oviduct of females: no glandular appendages, and no intromittent organ. Modifications of gills to form marsupial pouches. Development of germ: rotation of ciliated embryo. Metamorphosis of "Glochidium" and other larval forms of bivalves: final purpose of the deciduous byssus.

LIST OF SCIENTIFIC MEETINGS FOR THE WEEK.

This Evening,	April 24.	—Royal Institution. *Subject:* — Professor Faraday, "On Points Connected with the Non-Metallic Elements." Three o'Clock.
——	——	Medical Society of London. *Subject:*—Mr. Pilcher, "On Metastasis." Eight o'Clock.
Monday,	April	26.—Royal Institution. *Subject:*—C. B. Mansfield, Esq., "On the Chemistry of the Metals." Four o'Clock
Tuesday,	April	27.—Royal Institution. *Subject:* — E. Lankester, M.D., "On the Physiology of Plants." Three o'Clock.
——	——	Royal Medical and Chirurgical Society. Half-past Eight o'Clock.
Wednesday,	April	28.—Royal Institution. *Subject:*—C. B. Mansfield, Esq., "On the Chemistry of the Metals." Four o'Clock.
——	——	Hunterian Society. Eight o'Clock.
Thursday,	April	29.—Royal Institution. *Subject:* — R. Westmacott, Esq., R.A., "On the History and Practice of Sculpture." Three o'Clock.
Friday,	April	30.—Royal Institution. *Subject*:—Mr. Huxley, "On Animal Individuality." Half-past Eight o'Clock.
Saturday,	May	1.—Royal Institution. *Annual Meeting of the Members.*
——	——	Medical Society of London. Eight o'Clock.

Medical Times & Gazette.

SATURDAY, APRIL 24.

MR. PASCOE'S CASE.

Ma. Moorman's letter, which appears in another column, does not require any comment. While we willingly admit that this gentleman has acted conscientiously, and to the best of his judgment, we regret, that in so important a matter, he did not consult other authorities besides those he names. The very valuable letters we publish on the same subject from various able Correspondents, bring a mass of evidence to bear on the point, which cannot fail to satisfy both the Secretary of State, and the Judge (Erle) who presided, that the medical evidence given on the trial must be set aside.

On again carefully considering the entire evidence in this case, we cannot but feel the greatest astonishment that, even accepting Mr. Moorman's evidence, so able a Judge as the one who presided should not have sifted the case further. Is there any reason for this? It appears from Mr. Moorman's letter, that Mr. Pascoe has been tried for manslaughter. In passing judgment, also, the Judge (according to one report) made a statement, which, considering that there was nothing whatever to warrant it, in what had gone before, surprised us greatly. The Judge is reported to have said, that it was probable this was not the first time the prisoner had been guilty of a similar offence. Mr. Pascoe, we observed, also, called no witnesses as to character.

It is possible that, from circumstances with which we are unacquainted, there may have been a prejudice against Mr. Pascoe, which led the jury to conclude easily as to his guilt, and the judge to concur in this verdict. But with this we have nothing to do; we take the case as it stands, and, supposing that we have all the facts before us, we have no hesitation in stating, that the evidence tendered is insufficient to warrant the verdict.

The whole case will be amply investigated. The Judge is well known to be one of the most careful and conscientious men on the bench, and he will no doubt at once re-consider the evidence. We have reason to know, also, that our remarks have attracted notice in a quarter where no appeal for justice falls unheeded, and that Mr. Pascoe will not leave this country in a felon's garb, unless the verdict which has been recorded be warranted by a new investigation.

"THE SOULS OF THE SICK."

In a pamphlet entitled, "The Souls of the Sick,—a Letter addressed to Sir Robert Inglis, Bart., and the Governors of St. Bartholomew's Hospital;" written, we regret to say, by a member of the Profession, is an attack upon the conduct of two estimable gentlemen, clergymen of the Established Church, viz., the Hospitaller and Assistant-Hospitaller of St. Bartholomew's Hospital.

We notice it especially in this place, because one of the subjects touched upon is of considerable importance to the community at large.

It is not customary in the Nineteenth Century, to regard the souls of the Roman Catholic portion of Her Majesty's subjects as "sin-steeped and sin-directed;" and we presume the authorities of a large charitable trust would adopt very stringent measures to prevent their sphere of usefulness being limited by a spirit of bigotry. It is the pride of the present age, in reference to public hospitals, or the public services, that Protestant, Catholic, and Episcopalian, Presbyterian, and Dissenter, can sit at the same board, dwell under the same roof, and work for the same end in harmony and peace, each respecting and loving his neighbour. There will be firebrands and evil-doers in every community; but the general good sense will keep such culprits in their proper places.

We have heard that there exists an organized system of attack upon the Chaplains attached to public hospitals, on the ground, that they refuse *to proselytise* or to permit the introduction of such a system by others. If this be their *offence*, they merit the grateful thanks of the community that they have taken so high a position. The parent may leave her child, assured that no unfair advantage will be taken to shake its belief in the associations and the religion of its home. Men of all denominations know well, that their moments of anguish, or the hour of death, will not be imbittered by controversial divinity. Each patient has the benefit of the attendance of his own minister, unless he choose to avail himself of the services of the Chaplain, who in his daily visit to the wards solicits unobtrusively, yet earnestly, that they who are in distress will confide to him their woes. We should be sorry to believe that Mr. Hewer's opinions could affect the healthfulness of this system.

VALUABLE PUBLIC APPOINTMENTS.

The following advertisement may possess attractions to gentlemen of considerable independent property; especially as St. Mary's Hospital is situated in a fashionable part of

town, and is accessible by a pleasant drive round Hyde-park or a refreshing walk through Kensington-gardens. The officers of this Institution might, perhaps, prefer a Member of Parliament to undertake the posts they offer; the duties of watching cases uninterruptedly from day to day, and of noting the morbid appearances observed after death, being a light recreation, sufficiently agreeable to render men willing to undertake it *as honorary* :—

"St. Mary's Hospital.—A Medical and a Surgical Registrar are required for this Hospital. The offices are honorary, and the duties may be known by personal application to the Secretary, at the Hospital. "S. Shepherd, Secretary.

"Board-room, April 5, 1852."

The medical and surgical officers would have done themselves infinitely more credit, had they subscribed to pay the Registrar 100*l.* a year for conferring upon them so important a service as that of recording their cases for their own use. "A Medical and Surgical Registrar required at this Hospital; salary, 100*l.* a year, with board and lodging." Would not this have been more respectable from the authorities of a large public institution? We think so,—with the conviction, that the system of sucking the brains of the young without payment is derogatory to the high character of the medical staff of St. Mary's. The offer is positively shabby and discreditable; and we trust that it is a mistake soon to be corrected. As for ourselves, we would rather walk a thousand miles in a thousand hours, than pursue for *others*, without fee or reward, the varying characters of disease from day to day, without intermission, from their commencement to their termination. But, in these revolutionary days, society may be quite upset; and it would not surprise us were the next advertisement to be, "Acute Medical Cases and Surgical Operations required for this Hospital. Patients will be liberally paid, and the nature of the treatment may be known by personal application to the Secretary, at the Hospital. Board-room, April 1st."

ABSTRACT OF THE PROPOSED NEW CHARTER OF THE COLLEGE OF PHYSICIANS.

The preamble repeals former Acts and Charters, except such portions of the 32nd of Henry VIII. as may be consistent with the proposed Charter.

Clause I. Alters the title, from Royal College of Physicians of London, to Royal College of Physicians of England.

II. Provides for constitution of College, viz., fellow and members, including president and council, four vice-presidents, four censors, a treasurer, and a registrar.

III. All present licentiates to be members.

IV. All present extra-licentiates to be members, on presenting satisfactory testimonials of character, and on paying a fee of 15*l.* 15*s.*, exclusive of stamp-duty.

V. All persons, graduates of recognised Universities, practising as physicians, (and who have practised for three months previous to granting of charter,) and who do not practise pharmacy, to be members, without examination, on presenting testimonials and paying fees, any time within twelve months after granting of Charter.

VI. Graduates of recognised Universities, aged 26, to be subsequently admitted as members by examination.

VII. The present Fellows to continue Fellows.

VIII. Any member, of four years' standing, to be admitted a Fellow by examination.

IX. During twelve months after granting of charter, the Council may nominate, at discretion, any number of present members, without regard to the date of membership, to be Fellows.

X. After the twelve months aforesaid, the Council may yearly nominate, at discretion, members of four years' standing to be Fellows.

XI. Fellows to be elected by ballot, annually, on June 25.

XII. Provides for the expulsion of Fellows or members guilty of fraud, or imposition, or of violating by-laws, etc.

XIII. The presidentship to be annual; the present President to continue to be president till the day next after Palm-Sunday, and then to be capable of re-election.

XIV. On said day, the Council propose a Fellow from among the first fifty as president, to be elected by ballot, by a majority of the Fellows; if not received by the Fellows, a second nominee to be proposed by the Council from among the first fifty, and so on.

XV. On death of President, a new president to be at once elected, a vice-president officiating *pro tempore*.

XVI. The President to appoint four Fellows from among the first fifty as vice-presidents.

XVII. On death of President, the Vice-Presidents cease to be Vice-Presidents.

XVIII. The Council to be composed of sixteen Fellows.

XIX. Four of the Council to retire annually, and to be in capable of re-election for one year.

XX. The Council to be elected by the Fellows, in a method provided by the by-laws.

XXI. The President, Censors, and Treasurer, to be *ex officio* members of Council.

XXII. The Censors to be annually elected.

XXIII. The Council to nominate Censors, to be proposed to the Fellows, to be elected by ballot. If any proposed Censor be not elected, another Fellow to be proposed by the Council, etc.

XXIV. On death of Censor, a new Censor to be at once elected.

XXV. Treasurer to be annually elected, and to be eligible for re-election.

XXVI. In case of death of Treasurer, a new one to be at once elected.

XXVII. The Registrar to be annually elected, and to be proposed by the President to the Fellows. The retiring Registrar to be capable of re-election.

XXVIII. A new Registrar to be at once appointed in case of death.

XXIX. All the officers retain office during the day on which their successors are elected.

XXX. The days of election may be changed by by-law.

XXXI. No proxies allowed.

Subsequently it is provided :—

1 That the duties, powers, and privileges of the said offices be in future as they now are.

2. That the College may admit any person, aged forty years, after satisfactory examination, to be a member, and *to have and use the title of Doctor of Medicine*.

3. Powers are given to hold and inherit property, etc.

Clauses V. and VI. are drawn under the supposition, that the Legislature will in future, without interfering with existing rights, render it imperative on all physicians practising in England and Wales to be enrolled in the College of Physicians of England.

REVIEWS.

On Syphilis, Constitutional and Hereditary; and on Syphilitic Eruptions. By Erasmus Wilson, F.R.S. London: John Churchill, Princes-street. 1852.

Mr. Erasmus Wilson is well known as an honest and upright man, an earnest pathologist, an agreeable writer, the author of a standard work on Cutaneous Diseases; and of what, from the excellence of its pictorial, may be termed a national work,—"Portraits of Skin Diseases." We need therefore scarcely say, that his book on Syphilis commands attention. It is illustrated by some well-finished coloured drawings, which are excellent representations of syphilitic affections of the integument; and it is full of cases replete with interest. Mr. Ceely's experiments show that abrasion of the cuticle is by no means necessary to the success of vaccination; and hence our author justly infers that a similar law applies to the absorption of the syphilitic poison. This process he terms imbibition. The poison, after three to seven days, demonstrates its presence by local appearances; and Mr. Wilson believes that a man or a woman, having been once contaminated, and having been, to all appearance, cured, may nevertheless be so saturated with virus, as to possess the property of communicating syphilis to a sound person by means of the secretions.

Now, he relates the case of a gentleman, (p. 13,) who, having had gonorrhœa, but never previously a syphilitic sore, consulted him for a well-marked ulcer in the fossa glandis, which was followed by eruptions and sore throat. Latterly the patient had been living with a mistress, who enjoyed undisturbed health, and had left him to be married two months and a half before the commencement of his illness. He had no connexion with any woman between the time of her departure and the appearance of the sore in the fossa glandis.

"The mistress," says Mr. Wilson, "was the source of the syphilitic poison; the poison had been imbibed by the lover without lesion of surface; the sore in the fossa glandis was secondary, the produce of a secondary poison."

We confess ourselves sceptical as to the gentleman's story. A sore on the penis, followed by bubo, eruptions, and nodes, seems to us strongly like syphilis contracted in the ordinary way.

We think Mr. Wilson hasty in deciding a case to be of syphilitic character. For instance (Case 7)—a young woman, after marriage, suffers from excoriations of the vagina, the result of violence on the part of the husband. She then has an eruption of "red pimples;" then she falls into bad health, the tonsils inflame, suppurate, and burst. Are we not guilty of a gross injustice towards the husband to affirm, upon such evidence, that he has infected his wife with syphilis?

We turn with pleasure to the description of the different forms of cutaneous eruptions, and their transitions from one variety to another; they proceed, according to the author, from one syphilitic poison, and all the varieties of the manifestation of that poison, are due to modifications in itself; modifications having reference to concentration, assimilation, and susceptibility. For this subject we must direct the reader to the work itself. But we cannot quite understand Mr. Wilson, when he describes the following case as an instance of tubercula annulata after *gonorrhœa*. A young woman, aged 20, had gonorrhœa in the month of August; about Christmas she had a sore on the vulva; in the month of January she had an eruption on the skin. Now, why is the sore to be overlooked, and the secondary affection attributed to a previous disease, which rarely gives rise to any constitutional disorders of that character?

Mr. Wilson deserves thanks for his industry in collecting and recording the cases contained in his work; but we do not think that he is quite alive to the serious import of the conclusions which he has drawn in the chapter upon "Hereditary Syphilis," and which, in our opinion, are based upon insufficient evidence.

It is affirmed that the syphilitic poison, once received into the blood, remains there for life!! the infected wife must remain infected as long as she continues to live; the infected child must remain infected until death.—P. 158.

"The question then comes before us, What, 'if an infected child grown to manhood should marry? And with still greater force. What, if an infected child, grown to manhood, should marry the daughter of an infected wife? I feel convinced that a considerable proportion of those diseases which pass under the name of scrofula, are the produce of the syphilitic poison, are in fact not scrofulous, but syphilitic. In conclusion, I beg to repeat, that lupus, kelis, lepra and psoriasis, are forms of cutaneous disease, all having their origin in syphilis."

It were hard to say whether this assertion be most groundless, most absurd, or most pernicious; groundless, because there is literally no evidence worthy of value in its favour; absurd, because scrofula is known to be a term applied to an assemblage of symptoms, influenced by air, light, food, and other causes, and existing most where the luxuries and vices of society are unknown; pernicious, because it authorises a medical practitioner to insult an innocent parent with an infamous accusation. Is it not enough in a family, that a child should suffer from enlargement of the cervical glands and desquamation of the integument (a common occurrence in the highest circles), but that husband and wife must look at one another with suspicion, and mutually inquire from which side comes the syphilitic infection? Suppose that neither the man nor his father were ever so affected, is he justified in suing for a divorce on the ground that his wife has brought the venereal disease as a marriage portion? When in society we meet with a young lady, upon whose face or arm there may be a small patch of lepra, are the young men to point the finger of scorn at her as one syphilized? Mr. Erasmus Wilson would have it so; but he is not, we feel assured, aware of the needless misery that such an idea, once fostered, would create; nor does he seem to think, that such crude assertions, emanating from so respectable an authority, but rejected by the public, shake the confidence which should be reposed in us as well-judging and sober-minded men.

Life of Dr. John Reid, late Chandos Professor of Anatomy and Medicine in the University of St. Andrews. By George Wilson, M.D. Pp. 316. Edinburgh. 1852.

It will be in the recollection of our readers, that shortly after the death of Dr. Reid, in 1849, a Memoir of his life was announced from the pen of Dr. Rose Cormack, and that close upon the heels of this followed the announcement of a Memoir by Dr. George Wilson. Upon this, Dr. Cormack withdrew from the field; but finding, after the expiration of more than a year, that the promised work was still *in nubibus*, he placed his valuable papers at the disposal of a friend, by whom the interesting Memoir was written which appeared in the *Medical Times* for 1851.

The pledge of Dr. Wilson has been at length redeemed, although the words of the Jacobite song are applicable to the volume before us,—

"And oh! but ye've been lang a comin'!"

The purchasers of Dr. Wilson's Memoir will, however, have no cause to regret that it was anticipated in our pages, for from that source much valuable information has been derived, though, we freely admit, it is always acknowledged.

The present volume is a concise, well-written account of a life which did not admit of any great variety. Indeed, the author has shown his discrimination in not overdoing the sketch. The sad history of poor Dr. Reid's frightful sufferings and death, together with the change wrought in his mind, is simply but well told; and it certainly presents one of the most remarkable illustrations of the power of religion, in affording support under the heaviest trials that can befal a man. Interspersed throughout the narrative are comments and reflections; and we fully agree in the justice of the following remarks, which have reference to the removal by Mr. Fergusson of the greater part of Dr. Reid's tongue:—

"Here, surely, was a mournful combination of ingredients of humiliation and sorrow. But this was by no means all. The surgeons were the attached friends of the patient. They did not gather round him, with cold professional eye, to discharge an official duty. Fellow-lecturers, fellow-students, or fellow-scholars and old playmates, they all were; and now they were assembled to perform with grieved hearts a cruel and painful task. For doctors so circumstanced there is no sympathy in the unprofessional public heart. The surgeon who can lift his knife upon a friend is looked upon as little better than an assassin in spirit. Men glow over the tale of the Roman Brutus condemning his sons to execution; and women weep at the spectacle of Virginius stabbing his daughter to save her honour; but no one compassionates the surgeon who nerves his heart to inflict suffering upon one he dearly loves, or reveres the moral courage which guides his unfaltering hand."

There is, alas! but too much justice in these observations. Daily experience teaches us how lightly the world regard the feelings of a medical man, and how apt it is to confound his sacred calling with the indifference of trade. The petty dealer whose mind is cramped by retail dealings, thinks of cutting down to the lowest figure the hard and well-earned account of him who has laboured to restore the blessings of health; and he who calls himself an honest man, and who would cry shame on a starving wretch that steals a loaf of bread, thinks it perfectly fair and legitimate to "do" a doctor out of his fee.

To the thoughtless and unreflective, the perusal of the Life of John Reid will teach a solemn lesson, and no one can read it without serious thoughts, or exclaiming with the Preacher, "Vanity of vanities, all is vanity."

The Jacksonian Prize.—The Council of the Royal College of Surgeons have just awarded the Jacksonian Prize of 1851 to Dr. Edwards Crisp, of Parliament-street, for his essay on "The Causes, Diagnosis, and Treatment of Obstructions of the Intestines within the Abdomen." Dr. Crisp also obtained the same prize in 1845, for an essay on "Injuries and Diseases of the Blood-vessels."

PROVINCIAL CORRESPONDENCE.

IRELAND.

THE CITY OF DUBLIN SANITARY ASSOCIATION

Deserves much credit for its persevering efforts for the reform of abuses whose continuance can only be attributed to the supineness and negligence of those whose duty it should be to watch over the public health. Private associations must, however, he extremely limited in the field of their operations, and without assistance from influential quarters the labours of a few philanthropic physicians and private gentlemen cannot be expected to achieve much against such obstacles as are thrown in their way by the habits of confirmed negligence with regard to all that concerns personal and domestic cleanliness, and the ventilation and sewerage of their dwellings, which unfortunately characterise almost the entire of the poorer classes; while the operations of such bodies may be regarded as wholly ineffectual, as relates to those more extensive and important agencies in the production of disease which come under the heads of city sewerage, street and house ventilation, water supplies, both by river and pipes, etc. Nothing certainly conduces more to the preservation of health, than strict attention to personal cleanliness, not only as regards the body, but also the clothes; and, wherever facilities for bathing and washing exist, the dispensary medical officer should invariably impress this maxim on the poor, and take every opportunity to urge it on them for adoption. We notice with great pleasure that, owing to the enterprise of a few gentlemen, public baths have been recently opened in Dublin on a very commodious plan, and presenting to the poor the great inducement of extremely reasonsble charges, as low as twopence for a warm and one penny for a cold bath. We would only here observe, that the closing of the baths on Sunday appears to us a very unwise proceeding; many of the poorer classes are engaged in laborious occupations until a late hour on Saturday night, and are thus prevented from availing themselves of the baths, which they might, if kept open, say until 10 or 11 a.m. on Sunday. We learn that these baths have succeeded remarkably well during the short period they have been open,—little more than one month. While so much time is being lost about the Government Baths and Washhouses Bill, we would call the attention of physicians in our country towns to the example here offered them. A little judicious enterprise on the part of a few individuals could accomplish for each town what we cannot but designate as a real blessing to the poor.

At a recent meeting of the Dublin Sanitary Association, attention was called by Dr. Vance to the condition of the river Liffey, who stated, that it would be desirable that the Corporation should take some steps with regard to the bed of the river in certain situations adjoining the great thoroughfares of the city. The bed of the Liffey is in many places in a most disgusting and dangerous condition. The sweeping power of the stream is quite inadequate to keep it even moderately free from natural slime and artificial filth of all kinds, and at low water, especially in the warm seasons, the odours exhaled are of the most pestiferous kind, and salute the olfactory nerves of those whose business brings them within any reasonable distance of the river side, while they are absolutely intolerable at one of the most crowded bridges of the entire city. It was stated by Sir Edward Borough, that an intention was entertained by the Corporation to cause lateral sewers, running at each side of the river, to be constructed. We know of nothing which demands more prompt attention at the hands of those who are at all concerned in the cause of hygienic reform.

HEALTH OF THE CITY (DUBLIN).

Mr. James Houghton reported that epidemic fever of a very malignant type was still alarmingly on the increase. In Cork-street Hospital, on the 25th instant, there appeared 153 cases, the number of cases at the same date last year having been only 60. Up to Thursday there had been a death from fever every day in hospital. The sporadic type of fever this year was more fatal than he had known it to be for the last five years. There cannot be a more significant commentary on the present hygienic condition of Dublin.

We may take occasion here to remark the great want of some accurate general system of registration of the amount of disease and the mortality per cent. for any given period in the Irish metropolis. No city of such importance is in a more backward state in this respect, and, indeed, with regard to vital statistics in general: thus, it possesses no registration of deaths, births, and marriages, beyond that kept in a very loose way by the hospital and parish officers.

DUBLIN HOSPITAL GRANTS.

Petitions are about again to be presented in favour of the continuance of these grants. When we consider the extremely imperfect accommodation afforded by the present condition of the Dublin hospitals, as compared to those of other cities, in point of number of beds in proportion to the population, we cannot but think that any interference with their existing means of support would be an irreparable evil to the Dublin poor, and we trust that Government will see the justice of continuing these grants.

SURGICAL DIPLOMA OF THE UNIVERSITY OF DUBLIN.

Dr. Samuel Gibson, M.B. T.C.D., and scholar of the house, has had the honour of being the first to receive the new diploma of the Irish University, qualifying him to practise surgery. Dr. Gibson has thus enjoyed the advantage of completing his education in arts (an extensive and very successful one, as his rank of scholarship attests), medicine, and surgery, within the walls of the same institution. He has thus been saved the annoyance, expense, and trouble of going out of his native country to obtain a joint medico-chirurgical qualification, so indispensable now-a-days, but which it was next to impossible hitherto to complete in the Irish school.

APOTHECARIES' HALL OF IRELAND.—ANNUAL PRIZE OF FIVE GUINEAS.

The subject selected for the year 1852 is the following:—"The Indigenous Plants of the 'Dublin Pharmacopœia';" including their history, botanical character, their ultimate and proximate analysis, the average value of the several forms and menstrua ordered in the "Pharmacopœia;" with any improved formulæ for obtaining and preserving their active principles. The candidates will also be required to give in a written statement of the several processes adopted in each experiment, as well as of any chemical tests or physiological proofs made in evidence of their therapeutic efficacy. The examination will be held upon Monday and Tuesday, the 3rd and 4th of May next, and candidates are required to send their names to the Secretary of the Court a clear month before the days named for the examination.

We congratulate the Directors of the Apothecaries' Hall on the judicious selection made this year for the subject of their prize. It contrasts most favourably with that of last year; and we make no doubt that the result, as far as regards the acquirement of a sound and practical knowledge on the part of the candidates, will be most satisfactory. The subject is one also much more qualified to promote original observation among the students, and certainly far more conducive to the interests of science than a well-ground and parrot-like repetition of facts and theories common in every text-book.

GENERAL CORRESPONDENCE.

THE CASE OF MR. PASCOE.

I.

[To the Editor of the Medical Times and Gazette.]

Sir,—As your Article of the 17th instant contains remarks and severe strictures upon the medical evidence given by myself upon the late trial of William Hamlyn Pascoe at our March Assizes, I feel called upon to come forward and offer my statement of the circumstances and the grounds upon which that evidence was given; from which you will perceive, that the opinions contained in my testimony were not stated without consideration, or formed without a previous consultation of authorities upon the subject of savine as a medicinal agent.

My answers, then, to the judge, against the propriety of using savine as a therapeutic agent, were formed under the following considerations:—

1. Although I had been more than twenty years in practice, I had never used, or known any other practitioner to use, the drug.

2. Upon consulting Dr. Royle's Manual of Materia Medica, I find him giving the action of savine as irritant, so as to be even poisonous, and often used to cause abortion, although in small doses it is stimulant and emmenagogue. He gives the proportion of the oil at three per cent., and the dose from two to five drops. I find him, too, giving the authority of Dr. Pereira for the infusion of savine as an emmenagogue, but in so weak a form as one part of savine to sixty-four parts of water, the dose being half an ounce or an ounce, that I did consider fourteen or fourteen and a half drops of the oil, taken at three doses in the day, to be an excessive quantity.

3. Before forming my opinions, I had also consulted Dr. Paris's seventh edition of the Pharmacologia, where, after stating that Dr. Home, of Edinburgh, was in favour of savine as an emmenagogue, he declares, that the adverse opinions of Cullen had brought it into disrepute, as occasioning determinations of blood to the

uterus, and, if given in large doses, occasioning hæmorrhage and inflammation of the bowels, that its activity depends upon its essential oil, and that the old tincture is now removed from the London Pharmacopœia. He gives the dose of the oil to be from one to three drops.

These, then, were the authorities upon which I formed my opinions, which I declare, without fear of contradiction, were given upon oath conscientiously, and to the best of my judgment. Men in general matters hold various opinions; but in no cases are opinions more opposite or conflicting than in medical cases. I say here, that I still entertain the same medical opinions upon savine as I gave at the trial; and in the report of that trial the fact ought, in justice to myself, to have been more prominently set forth, that I distinctly stated, that the quantity of oil of saviue ordered by the prisoner would not produce dangerous effects upon the woman, but might produce the peculiar effects of savine—as irritation and purging; and that, as a consequence of this, miscarriage might take place.

If any of my opinions are erroneous, I have the satisfaction of knowing they were not hastily given; and if by the majority of the Profession they are held to be erroneous, no one could more deeply regret than myself the effects of these opinions, or more earnestly desire (as you suggest) an application to the Secretary of State for a re-consideration of the prisoner's case.

As you, in support of your medical judgment, have alluded to some circumstances not directly medical, I think it but fair to explain upon one of them. You say, and say truly, that Mr. Pascoe, in order to get the child buried, sent for the parish sexton's assistance. It might have been added, that the sexton's daughter lived with Mr. Pascoe, and was concerned in the secret care of the woman in her premature birth.

That, in giving my evidence, I was influenced by no one motive but the proper one, may be inferred from the fact, that, when this same Mr. Pascoe was, twelve months before, indicted and tried for manslaughter, my evidence upon certain symptoms of poisoning by opium was so directly opposed to the symptoms stated by another medical man to have been found in the case, that an acquittal followed; and here I may observe, that it may appear singular, that upon each of these trials I was the medical witness called. I was called upon, however, by proper authority, and I felt upon each occasion that I ought not to shrink from a duty, however disagreeable that duty may be; but, at this last trial, I particularly suggested to the parties concerned in the prosecution that some other medical evidence should be taken.

I am, &c. WM. MOORMAN, jun., Surgeon.

St. Columb, Cornwall.

II.

[To the Editor of the Medical Times and Gazette.]

SIR,—I scarce need apologise for troubling you with this letter, as it is our duty ever to defend the right, and, in the case of Mr. Pascoe, lately tried at Bodmin, the right seems so loudly to call for defence, that I have dared to lift up my voice on its side; I hope, however, that other voices, which carry more force than mine can, will not be silent, but will declare themselves loudly, and make themselves heard in the quarters where they can effect most good.

It appears that Mr. Pascoe was convicted chiefly on the medical evidence given by Mr. Moorman, surgeon of St. Columb Major. In your article of the 17th inst., you declare your opinion, that Mr. Moorman's statement is a mistake from beginning to end. In this opinion I fully and entirely concur.

Mr. Moorman has committed a gross error in swearing that no man of competent knowledge would administer oil of savine in such doses as those ordered by Mr. Pascoe, unless for the purpose of procuring abortion.

What can Mr. Moorman have been thinking of? Can he, indeed, have been thinking at all? Surely the charge of want of competent skill should be shifted from Mr. Pascoe's to Mr. Moorman's shoulders.

Savine is still used as an emmenagogue by many medical men; the oil is the preparation generally used. To produce the emmenagogue effect, large doses are often necessary.

Hear what some authorities say on the subject, and contrast Mr. Moorman's statements by the side of them; and then judge you which are the worthier of trust, the men whose written opinions I have quoted, or Mr. Moorman, the despiser of Hooper.

MOORMAN.

"It has been used for disease of the womb in old practice."

"Three doses daily, 36 drops, would convey about 14 drops of oil of savine; and used in that quantity, I am of opinion this medicine would produce the peculiar effects of savine, such as irritation, or purging, or inflammation probably of the large intestines, and, as a consequence of that, miscarriage might take place."

In answer to questions by the Judge, etc.—

"I think a man of competent knowledge would not prescribe it in such quantities (14 drops daily), except to produce abortion."

"I think that a man ought not to prescribe such a thing in such quantities for any legitimate purpose."

"Unless the object were to produce abortion, the prescribing such quantities would indicate want of skill.

"Even in the old practice, I do not think so large a quantity of savine would be used."

"Fourteen drops of the oil daily too large a dose to be used, excepting to produce abortion."

CONTRA.

ASHWELL.

"Savine, the juniperus sabina, is a powerful stimulant and emmenagogue; but its use is at present much restricted. Its deobstruent power is attributed to a volatile oil. . . . Where there is a feeble and languid circulation savine is a suitable stimulant, but its use is injurious where there is plethora and irritation. . . . . Of the oil, from 2 to 20 drops may be taken two or three times daily."—P. 83.

BOVIN.

"Some of these substances, besides being general stimulants, act in a special manner upon the uterine organs, and are termed emmenagogues. The use of these remedies, combined with strict regimen, is more proper in the present affection (amenorrhœa) than in dysmenorrhœa. Aloes, rue, and savine have often been found efficacious."—*Practical Treatise on Diseases of the Uterus*, p. 427.

BRANDE.

"It is perhaps the most powerful uterine stimulant of the Materia Medica, and is occasionally administered in amenorrhœa, though always requiring the utmost caution lest it induce inflammatory action."—*Materia Medica, Art. Savine*, p. 152.

BALLARD AND GARROD.

"Savine is a topical irritant, rubefacient and vesicant, and has been recommended for internal use as an emmenagogue."—*Materia Medica*, p. 334.

HOOPER (GRANT'S EDITION).

"Savine is a powerful and active medicine, and has been long reputed one of the most efficacious in the Materia Medica for producing a determination to the uterus, and thereby proving emmenagogue. . . . . Dr. Home appears to have had very great success with this medicine, for in five cases of amenorrhœa which occurred at the Royal Infirmary at Edinburgh, four were cured by sabina, which he gave in powder, from a scruple to a drachm, twice a day."—*Medical Dictionary*, p. 810.

PEREIRA.

"The emmenagogue power of savine is fully established. . . Savine is not much used internally; but in cases of amenorrhœa and chlorosis, depending on, or accompanied by, a torpid condition or deficient action of the uterine vessels, it may be given as a powerful uterine stimulant. In such cases it proves a most efficient remedy. According to my observation, it is the most certain and powerful emmenagogue of the whole Materia Medica. My experience of it, therefore, confirms the statements of Home. Though I have employed it in numerous cases, I never saw any ill effects result from its administration. Fodéré relates a case of a woman who, to produce abortion, took every morning for 20 days, 100 drops of the oil, and yet went her full time, and brought forth a living child.

Emmenagogue Dose of the Oil.

Pereira—From 2 to 6 drops.
Ashwell—Maximum dose, 20 drops, 2 or 3 times a day; or, 60 drops daily.

I am, moreover, of opinion—and my opinion is not formed without experience—that savine is far less powerful to produce abortion than is popularly believed. Drs. Pereira, Ballard, and Garrod, all agree that it is less likely to injure the fœtus than the mother.

If it ever does produce abortion, it always at the same time makes the mother ill. Pereira says, "It ought to be well known, that in those cases in which it may succeed in causing miscarriage, it can only do so at the risk of the woman's life." Now, is it probable, that a drug which thus produces its effects on the fœtus by causing a dangerous state of the mother, could have procured abortion without any uncomfortableness, as it is said to have done in this instance? Look at the case. Miss Nicholls took 14 drops

of the oil daily "for some time," yet, when the bottle was finished, was she ill? Had the medicine made her feel ill? No; for she says, "I thought I was better." Being improved, she ceased taking the drops, and Mr. Pascoe gave her pills to take. (What were they?) The pills came to an end, and then she visits Mr. Pascoe again. This time she stays in his house, and takes no other medicine than salts, (daily quantity not stated,) and lo! she miscarries. At once the blame is laid on the oil of savine, and Mr. Pascoe is charged with giving it to cause the uterus to throw off its contents.

Let us reason on these points. It must be observed, that some weeks elapsed between the time she ceased taking the savine, and the day on which she aborted. She made two journeys from Probus to Cubert, and took a box of pills between the journeys.

Is it probable, that a medicine which can only induce abortion by producing a powerfully acrid and irritating action on the mother, so as often, indeed, to endanger her life, can have acted in this case, and caused expulsion of the child, although a considerable time had elapsed since she had ceased to take it, and although she had felt better than usual while under its influence? —the girl, be it borne in mind, being a sufferer from a dangerous disease of her heart, a condition, of course, rendering her more obnoxious to suffer from any disturbance. I think the opinion of all medical men will be against such an opinion, and yet such is said to have taken place in the case under consideration.

I have shown some good written authorities, all tending to overthrow Mr. Moorman's evidence. I believe, were all the medical men in the land to record their opinions, Mr. Moorman would find himself in a ludicrously small minority. I cannot but blame Mr. Rogers for not having consulted other medical opinions. Bodmin contains some men well able to give a good opinion.

What other evidence tending to criminate him might have been put in, I know not; but, as it was not put in, and as that which was put in was untrue, the man must of a necessity be innocent, because no proof of guilt is given.

The rest of the evidence is of little weight. There is decided failure in the attempt to prove Mr. Pascoe's cognizance of Miss Nicholls' condition. Mrs. Catherine Hockin sees Miss Nicholls opening the front of her dress, and, with a truly feminine suspicion, thinks it is to examine her breasts. What can a man want to see there but the breasts? Oh, yes, it must be the breasts; and dark suspicions crowd on the matron's mind. Alas! but too true. But Mrs. Hockin never saw Mr. Pascoe examine the bosom; she only saw Miss Nicholls opening her dress,—the good dame's fancy finished the operation. Mr. Pascoe wanted to examine his patient's heart; he did so. A medical man, in auscultating and examining a heart, seldom notices the breast at all, much less the areola. There is then no evidence that Mr. Pascoe examined the breasts, or was aware that the girl was pregnant. She herself had never told him. How was he to know?

Most probably he was aware of the absence of the catamenia, and might believe that the re-establishing of this functional discharge would aid in relieving the heart, and gave the savine with this view. It is not a question whether in doing so he did wisely. The point at issue is, whether he did give the oil of savine with this legitimate and justifiable extent, or whether with the criminal one of procuring abortion. Is there any evidence of the latter? None. Then we are compelled to believe the former, and to acquit Mr. Pascoe of the charge laid against him.

I trust that you, Sir, with the other powerful ones in our Profession, will not fail to exert your powers to render justice to Mr. Pascoe.

Mr. Moorman, too, who must see the error he has made, will, I trust, show himself a brave and honourable man, by coming nobly forward and avowing his error, and thereby make all the reparation he can. I am, &c.

EDWARD WILLIAM LOWE, M.R.C.S.E.

Congleton.

III.

[To the Editor of the Medical Times and Gazette.]

SIR,—I think every respectable member of our Profession must feel the justice, truth, and charity of your able remarks upon the trial of the unfortunate Mr. Pascoe, and his condemnation to the society of felons and murderers for the next ten years of his life, upon the erroneous evidence of a professional brother. Professor Christison states, in his "Dispensatory," second edition, 1848, that "the emmenagogue virtues of savine deserve attention." Those virtues have been recently commended in strong terms by Dr. Pereira, who says, "he has never met with any of the unpleasant effects on the bowels and kidneys so generally dreaded by practitioners."

Again, Professor Christison says, "this drug is believed by the vulgar to possess the power of inducing miscarriage, and is sometimes used by them for perpetrating this crime. But it cannot act in such a way without violently affecting the stomach and bowels, and so bringing life into extreme danger." He fixes the dose of sabinæ ℥ij. ad ʒv.

Surely the opinions of Mr. Moorman cannot be placed in the balance with such testimony; surely it was his duty to give the unhappy prisoner the benefit of such testimony, and surely it is now his duty to make a manly avowal of his error. I know nothing of the antecedents of either Mr. Moorman or Mr. Pascoe, and judge only from the report of the trial, which has strongly impressed me with the feeling of an innocent man being condemned to a punishment worse than death.

I trust, Sir, you will not allow your able pen to sleep in this sad affair, and I must hope with you, that some influential members of the Profession will bring this case before the Secretary of State; and I must further hope, that the Profession generally will be ready, if necessary, to use every exertion,—if so, the result cannot admit of doubt. I am, Sir, &c.

Bankside. W. O. BELL IRVING.

IV.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am indeed surprised on reading the testimony of Mr. Moorman, given against an unfortunate apothecary, Mr. Pascoe, at the late Lent Assizes, held at Bodmin, in the county of Cornwall. Mr. Moorman has not displayed an overstock of competency to practise his profession, in stating that a man of competent knowledge would not administer fourteen drops of the oil of savine in twenty-four hours except for abortion. Dr. Pereira states, in his second edition of Materia Medica and Therapeutics, etc., vol. ii., page 1068,—"In cases of amenorrhœa and chlorosis, depending on or accompanied by a torpid condition or deficient action of the uterine vessels, it may be given as a powerful uterine stimulant. In such cases it proves a most efficient remedy. According to my own observation, (Dr. Pereira,) it is the most certain and powerful emmenagogue of the whole Materia Medica. My experience, therefore, confirms the statements of Home. Though I have employed it in numerous cases, I never saw any ill effects result from its administration. In chronic rheumatism, with a languid circulation in the extreme vessels, Chapman, in his Elements of Therapeutics, speaks in very high terms of it. It has been used as an anthelmintic. The dose of the oil of savine as an emmenagogue is from two to six drops diffused in a mucilaginous or oleaginous mixture." This, I should suppose, would be sufficient proof that the oil of savine may be used with safety and in larger doses than that given by Mr. Pascoe to Miss Nicholls. Again, Dr. Locock (no mean authority), in the "Cyclopædia of Practical Medicine," vol. i, page 69, speaks highly of a combination of myrrh, aloes, sulphate of iron, and essential oil of savine, in amenorrhœa. Yet, in the face of the opinions of these two great men, Dr. Locock and Dr. Pereira, both sanctioning the use of it, Mr. Moorman states, in answer to the first question put by the Judge, that no medical man would administer savine except to produce abortion. His ignorance or want of competency at last comes out; he says, "he knows there is a book called 'Hooper's Medical Dictionary;' I do not use it myself, but I have known it used by medical men; it is not in general use." I must here beg to inform him, that there are few, very few, medical men who do not possess it, Mr. Moorman one of the few. It is indeed a valuable book of reference, both for old and young practitioners. Evidence given by such a man, who evidently is not aware of such books as "Pereira's Materia Medica," or "Churchill on the Diseases of Females!" I must agree with you, Sir, that there is not the least evidence against Mr. Pascoe that he administered the oil of savine with intent to produce abortion. If there were any medical men in court during the trial, they ought in justice to their own professional characters to have informed the counsel for Mr. Pascoe that Mr. Moorman was labouring under a very great mistake; probably then the unfortunate man would have been acquitted, instead of being sentenced to ten years' transportation.

I sincerely hope some leaders of the profession will make out a clear case, and lay it before the Secretary of State, whose quick discernment will, I am sure, lead him to see that Mr. Pascoe has been convicted on very mistaken evidence.

If we administer savine, after such a verdict, to a patient, it is sure to be considered as used with intent to produce abortion; the consequences, of course, are ten years' transportation, to which every one of the Profession will be liable. I fully believe not a single medical man is safe; I am not. It is a very favourite medicine with me, combined with aloes and iron, in cases of amenorrhœa and chlorosis; but, if I am liable to transportation,

am bound to discontinue its use, therefore my patients must suffer from complaints with which it has pleased the Almighty to afflict them. He has sent various remedies for various complaints, but we are not allowed to make use of them. I am very sorry to trespass at such an unusual length on your valuable columns; but, when we see ignorance in full bloom, it is enough to rouse any one; and I am sure you will not allow the case of Mr. Pascoe to pass over without giving the Profession an opportunity of expressing its utter indignation at its result. I am, &c.

Mile-end. A Subscriber and M.R.C.S.L.

V.

[To the Editor of the Medical Times and Gazette.]

Sir,—Having just read your account of Mr. Pascoe's trial, and also your remarks, I hasten to express my entire concurrence with the latter, and to express a hope that the suggestion in your closing paragraph will be immediately acted out, for it cannot be that, upon such evidence, the "Profession" will quietly allow a "brother" to be transported for ten years. I have always thought that a prisoner, even of the worst description, had the benefit of a doubt. Surely, in this case, there was ample room for such mercy, at the least in mitigation of punishment. Can it be evidence of intended guilt, "acting in accordance with an acknowledged authority," "writing a prescription to be made up by a chemist," and "sending for the sexton," not to mention other things.

Why, Sir, what can the counsel have been about? Is it not a well-known fact, that females so situated, especially if respectably connected, apply for medical advice for a particular complaint, for the express purpose of getting rid of the cause of their shame, carefully concealing everything likely to create a suspicion of the truth. Are we, then, to suspect every unmarried female, and, in fear of transportation, also give up the brightest ornament of our professional character, that of carefully concealing the faults of our patients, whether male or female, under which honourable feeling I cannot help thinking Mr. Pascoe has risked his own character rather than betray that of his patient; and, admitting he may not have been very prudent in all the circumstances connected with the present case, where, as you justly observe, is the proof of intent? Certainly not in the evidence. Again expressing a hope, that, for the honour of the Profession, no time will be lost in securing a re-hearing of the case, I am, &c.

Humanitas.

P.S. Ought not the Apothecaries' Society to take the initiative in defence of a licentiate thus situated?

VI.

[To the Editor of the Medical Times and Gazette.]

Sir,—On reading your leading article last week, referring to the case of William Hamlyn Pascoe, I referred to Pereira's "Elements of Materia Medica," and found the following very decisive paragraph, vol. ii., p. 726: "Savine is not much used internally; but in cases of amenorrhœa and chlorosis, depending on or accompanied by a torpid condition or deficient action of the uterine vessels, it may be given as a powerful uterine stimulant. In such cases it proves a most efficient remedy. According to my own observation, it is the most certain and powerful emmenagogue of the whole Materia Medica. My experience of it, therefore, confirms the statements of Home, ('Clinical Experiments.') Though I have employed it in numerous cases, I never saw any ill effects result from its administration."

Dr. Nevins, in his "Translation of the New Pharmacopœia," quotes from Pereira, and gives the dose of the oil from mij. to mvi. The prisoner gave doses of four drops and a half.

This is so thoroughly at variance with the opinion of the medical witness, which opinion appeared to influence the mind of the Judge more than any other evidence, that I lost no time in sketching a letter to the Secretary of State, in which I placed the paragraphs from Pereira and Nevins side by side with the evidence of Mr. Moorman.

May I urge upon some of your readers to follow up the application to the Secretary of State with other letters, and he will, no doubt, look at the faulty evidence, and not allow the sentence to be carried into effect, if the verdict has been founded solely upon evidence which shall be proved to be erroneous. I am, &c.

Bedford. T. Herbert Barker, M.D.

ON UTERINE DISEASES AND THEIR TREATMENT.

[To the Editor of the Medical Times and Gazette.]

Sir,—In an Editorial Article in the *Medical Times and Gazette* of March 20th, a hope is expressed, that some gentlemen will assist by *post-mortem* examinations at several metropolitan hospitals, to elucidate the *quæstio vexata* as to the frequency of uterine ulceration.

Fully believing that truth is your sole object, and not the giving a colourable assistance to any party purpose or prejudice, I am at a loss to know why the investigation should be confined within the narrow limits of ulceration, and not embrace the various other abnormal conditions of the uterus and its appendages, seeing that they are equally, or even more, prominent in their effects upon the female system.

All who have made uterine pathology their study must earnestly desire every legitimate method of investigation and the most searching scrutiny into this class of diseases, feeling as assured as they are of their own existence that any inquiry, conducted with impartiality and care, and made upon proper subjects, will tend to substantiate the statements of those who affirm from their daily practical experience, that these maladies, in their various forms and phases, are among the most frequent the physician is called upon to combat with.

But, by the plan proposed, will proper subjects be obtained for the examination? or, in other words, do hospital female patients constitute a fair sample of the general female population? I think not. I fully agree with the opinion so ably and eloquently expressed by Dr. Murphy on a recent occasion, in a speech, which, for manliness of spirit and vigour of style, deserves to be printed in letters of gold.(a) "That women do not die of such diseases. They very seldom enter general hospitals; and if, in consequence of other complaints, they become inmates and die there, they are placed under circumstances that would contribute more than any other to arrest the progress of the primary affection; they are kept perfectly at rest, and morbid action is going forward in another place; hence, if they had such a disease, it is highly probable that there would be no trace of it before death."

Waiving, however, this objection, it may be very pertinently asked, why autopsies should be required to settle the question? Are the statistics of the dead-house alone trustworthy, or, rather, are they at all to be relied upon,—at all events in uterine ulceration, when in one and the same Report(b), Mr. Pollock, ("whose facts," Dr. J. A. Wilson says, "might be depended on," as "it was his" (Mr. Pollock's) "custom to have all women who died in the hospital examined as to the condition of the uterus and ovaries whatever might be the disease they died of,") states, according to Dr. R. Lee, that in 583 autopsies he did not find a single case of simple ulceration of the os uteri, and only 23 of diseased mucous membrane of the uterus; while Dr. Murphy clearly demonstrates, from the same Report, that 62 cases, at least, of that number of 583, belong, by Mr. Pollock's own showing, to the class of uterine disease the result of inflammation? That, by some means, grave oversights or mistakes have arisen in the course of Mr. Pollock's dissections, and, consequently, got into his Report—mistakes which nullify all his conclusions and render his labours useless—is fully and satisfactorily established by Mr. Holl, who states, that last year, at the same hospital which furnished Mr. Pollock's statistics, out of 44 women who died there, and "in which the state of the uterus was examined," disease was found in 13, or very nearly 1 in every 3! What inference can be drawn from such unsatisfactory statements beyond this,—that, valuable as *post-mortem* evidence unquestionably is, when carefully and impartially conducted, it may even unintentionally be made the means of deceiving us, and therefore should be received with caution when its supposed results lead to doubtful and suspicious conclusions.

We shall arrive at far more valuable facts and incontrovertible statements, if every British practitioner, who has experience of and practice in uterine disease, would come boldly forward and give the medical world the benefit of his knowledge. Let him relate his cases; show how others of his professional brethren, holding views opposed to his, have let their patients linger on for years in hopeless misery and distress, until he has been summoned to their aid and restored them, if not in every case to health—for that, perhaps, has been irretrievably lost by long neglect or something worse—at all events to comparative ease and comfort. The gentleman so practising "may find himself surrounded by rumours that he is treating complaints which have no existence,"—for rivals are often not scrupulous as to the weapons they use or the assertions they make to serve their nefarious purposes,—besides whom there will be found in every community some men prejudiced against all innovations, and others too indolent to adopt them; men who will never learn; will never advance with the times, but remain the same yesterday, to-day, and for ever; these it is not my

(a) *Vide* Report of the Royal Medical and Chirurgical Society meeting, *Lancet*, Feb. 7, 1852.
(b) Ibid.

intention now to notice, but it appears strange that any number of men so intelligent and intellectual generally as medical men are acknowledged to be, should act differently, both diagnostically and therapeutically, with regard to the uterus to what they do with any other part of the body, without any sufficient reason being adduced for the deviation. If the physician has a patient with obscure abdominal disease, does he not use every means in his power to arrive at true pathological conclusions respecting it? Does he not notice the aspect—the eye, the skin; watch the secretions and excretions, carefully ascertain whether tenderness, or induration, or protrusions exist, and even then sometimes feel regret that he cannot for a moment look through that thin tegumentary covering which hides from him what he would so gladly know?

When the surgeon is called to a case of inflammation of the eye, is not his first step to see what state the organ is in? Then, but not till then, does he not, as circumstances demand, deplete, counter-irritate, or, if an ulcer be there, will he not use caustic? And he does all this notwithstanding that he is fully aware the patient's constitution is at fault, and requires constitutioual treatment, which he will take care to have contemporaneously carried out.

But, "in disorders found affecting the uterine system," we are told, "that our remedies, if their use is to be attended with success, or their administration founded upon pathological investigation," they "must be directed to the general system, cautiously, if not sparingly, and in most cases not at all directed to the part itself." And this is because "almost in all cases constitutional affections may be detected, not only propagating but maintaining local diseases and local derangements."(a) When this is said of cancer and other incurable blood diseases, in which the local manifestation is only typical of the general contamination, we understand and appreciate the warning it conveys, viz., that all attempts to cure by local means are for the most part useless, and frequently injurious. Experience also tells us, that in such cases constitutional treatment is almost invariably equally impotent, and the patient, in a few months, dies worn out by suffering. But this, so obviously, is not the progress of uterine affections, that we are driven to believe the writer of the paragraphs quoted above does not wish to convey so palpable an absurdity as his words would at first sight appear to indicate, viz., that a common ulcer on the womb is as difficult to cure as a cancerous breast; that he does not intend to assert there is a special and peculiar uterine pathology altogether different from the ordinary pathology of the general system, but only what every tyro in the Profession ought to, and probably does, know, that uterine, in common with most or all other local diseases not occasioned by injury, have a constitutional origin, either inherent or acquired—that is to say, they would not arise if the person was in a sound state of health previously.

Well, then, does this constitutional origin preclude or forbid our using local remedies, when we have localised disease under our care in other parts of the body besides the uterus? Decidedly not. Take the case of an ulcer of the leg. I have just now cured one which has been twenty-two years open. The constitution was clearly at fault, as shown by the long continued deficiency of bile and costive evacuations; the skin of the limb was of a dull chocolate-red, and the veins were slightly dilated. I gave local support by strapping; I applied a local stimulant (caustic); I ordered constitutional means, and, in thirteen weeks from the beginning of the treatment, the man was well. All the remedies directed alone to the general system that the world can boast of, would never have cured this man without the use of local means. And so it is in the vast majority of the cases of ulcerative disease of the womb. But, perhaps it may be argued, that there is a difference between the uterine ulcer and the ulcer on the leg; so there is, but the difference is often one of situation only, and, could we apply the same treatment—caustic, support, and rest—to the former as we can to most of the latter, we should very much abbreviate the duration of the case. This, of course, is impossible, so far as support is concerned, and even rest is very difficult to be obtained; for patients with extensive uterine ulceration will frequently perform all the acts of life as if no disease existed; and here again the analogy between the two cases is striking. Some time ago I had a man under my care with a deep fetid ulcer on the leg extending nearly round the calf, yet he would constantly walk from Launceston to Plymouth, a distance of twenty miles, without, as he assured me, being inconvenienced by his wound.

I do not say, that the vis medicatrix naturæ may not occasionally act with uterine ulceration, as it sometimes, but very rarely, does in tubercular ulceration of the lungs, and I believe the spontaneous cures in the two situations are, under ordinary circumstances, nearly equal in frequency. If my opinion be anything like an approximation to the truth, can any man for a single moment think he is doing his duty to his patient by leaving her to this remote and almost hopeless contingency, when he can convert doubt into certainty, despondency into joy, and pining sickness into blooming health, by the mere passing of a speculum, sweeping a stick of caustic over a sore, or applying a few leeches to an inflamed and indurated organ?

The public should never know of our professional differences, nor be called in to judge between us, or I would say, let the patient herself decide the course she would prefer,—whether to linger on for years an invalid, or be cured in a few weeks by the aid of an instrument which, when properly used, outrages no feeling of delicacy in its application, is unattended by pain, and against which the only argument is, that it may be, nay is, used oftener than necessary. For what purpose—for the sake of gain? That can scarcely be, for the medical man charges for his attendance, whether he uses the speculum or not, and he would save both time and trouble by its being discarded. He who practises his profession in all its various departments, either as a physician or surgeon, can have no motive for asserting that a patient has uterine or ovarian disease when she has not, for what object could be gained by his making it appear that her disorder was in one part of the body where it was not, rather than in another where it really was. He would not be paid more for attending her if the disease was in the uterus, than he would be if it was in the stomach, or liver, or heart, or lungs. We may take it for granted, that she has something the matter with her, for, with the exception of some few hypochondriacal idlers—a race fast dying out—persons, although they will swallow quack nostrums *usque ad nauseam*, and get their friends and druggists to assist them in the endeavour to ascertain which will ruin their constitutions soonest, yet very rarely seek the regular practitioner until they are really ill.

But it may be said that the physician accoucheur has a motive for asserting that uterine disease exists when it does not. I pity the poor grovelling mind that would harbour so base a suspicion. It is not, however, necessary for me to vindicate the honour of the profession it is my privilege to belong to; suffice it to say, although some may be found in it, as in every other walk of life, unworthy their vocation, their number is few indeed compared with the noble hand whose life-long object is the relief of suffering,—men who have a higher principle of action than mere gain, and who would as soon lose a right hand or eye as be guilty of a meanness or a falsehood.

The only other inducement for the too frequent or unnecessary use of the speculum must be that arising from improper feelings—a supposition too horrible to be entertained even for an instant, and which I at once dismiss from consideration with the deepest disgust and loathing.

It has been asserted, that ulceration of the os and cervix uteri is always of a specific character, that it is either syphilitic, or scrofulous, or cancerous. I cannot agree in this opinion, notwithstanding the wide range it is capable of being stretched to; at the same time it must be conceded, that ulceration and other forms of uterine disease are, as might *à priori* be expected, much more frequently met with in delicate persons, and those contaminated with one or both of the first-named diseases than in sound and healthy women; or, in other words, are more often the result of constitutional debility or disease than of local bruise or injury.

Well, then, taking it for granted that the uterus and its appendages are sometimes in an abnormal condition, and that they are governed by the same laws as the rest of the body, why should they not be equally carefully and minutely examined when sufficient and cogent reasons are adduced for supposing that disease is present there?

The medical practitioner can have but one valid reason that I can see for not doing so, and that is a praiseworthy one—a sense of his own utter ignorance of those diseases, even when they are presented in their most cognate forms to his notice.

But all men are not candid and honest; it is painfully interesting to see the various shifts and devices used to hide a want of knowledge. Some boldly proclaim there are no such diseases; others, more timid, assert their infrequency, and the non-occasion for interference; some "don't use any examination;" others "don't use instruments, being satisfied with digital investigation," and probably view their "educated" finger with the same complacency as they do the bee's-wing in their port,—very pretty to look at, but of no real value or utility. Again, some, descending in the scale, (and *facilis descensus* when interest prompts them,) if they can get hold of another man's patient, assert she has had nothing the matter with her womb,—that her constitution has been ruined by the unnecessary interference, but they will do their best to remedy the evil; others go bluudering on, can't find the os uteri,

(a) *Vide* Report of the Royal Medical and Chirurgical Society meeting. *Lancet*, Feb. 7, 1852.

or do not know when they see it; but, being told there is an ulcer there, apply caustic where they can, and leave the patient worse than they found her, or, what is even more to be regretted, herself prejudiced against the very means which, properly applied, would cure her.

This may appear to many as much overdrawn, or too highly coloured; it is neither; and, before this series of papers is concluded, I will, with the Editor's permission, and without travelling from my immediate subject, prove my assertions.

One or two cases I will now subjoin. A few months since, Mrs. W. applied to me with symptoms indicating disturbance of the uterine system. I accordingly examined her, and found, on the posterior lip of the os uteri, an ulcer of the size of sixpence, which bled on the slightest touch. Considering the case would require more time than I could bestow on it, I declined attending her, but stated what was the matter, and advised her to employ some other medical man, who, while he would give the necessary attention, would not charge her as I should be obliged to do. I heard nothing more for some weeks, but at length was sent for in consultation, and, on examination, found the ulcer on the os unaltered, but, in addition, another on the wall of the vagina, not opposite to, nor in possible approximation with, the uterine one. On inquiry, it appeared that my medical friend, whose locks have grown not only grey, but white, in the Profession, had, in conjunction with a gentleman equally mature, repeatedly examined Mrs. W., understanding that she had an ulcer somewhere, but, being unable to find it, they had applied caustic where they could! I am warranted in drawing this conclusion, for, when I passed his instrument, (a tarnished, long-handled original three-bladed machine, which he had a short time before bought second-hand at a sale!) I showed him the uterine ulcer and his own, and applied caustic to both. On my next visit, feeling myself ill, I requested him to see what progress had been made, but he could not then even show me the ulcer, and, after fumbling about for some considerable time, he removed the ponderous weapon, remarking at the same time, "You know, Dr. Roe, she complains of pain directly above the pubic bones," indicating with his hand where that region was! I know nothing more of the progress of the case, beyond that I again showed him the ulcers, which were already looking healthier, and left him in possession of the case.

I have many times found considerable difficulty in bringing the os uteri into view, especially when using the bivalve speculum, and when the uterus has been much displaced; but in this case there was no obstacle, except that furnished by the operator's want of skill.

About eighteen months ago, a poor woman, living some miles in the country, applied to me for advice with profuse menorrhagia. On examination, I found a polypus of considerable size proceeding from the mouth of the uterus. She had been under the care of a medical gentleman of talent and experience for some time, who, although he had attended her in her various accouchements, had never even proposed an examination. I sent her to him with a note, stating the nature of her disease, and he speedily relieved her of the malady by the ligature.

On June 10, 1849, I was consulted by Mrs. J., from Callington, a tall, well-formed person, but of pale and suffering appearance. She stated, that for some two or three months she had been afflicted with pain similar, and equal in severity to that of labour. Her surgeon had been in attendance upon her during that time, but had done nothing in the way of examination beyond pressing the abdomen outside her clothes. She was the mother of several children. On examination per vaginam I found the uterus healthy, but a large tense elastic tumour, situated at the posterior superior part of the vagina, between the uterus and rectum, but apparently springing from the uterine wall. It conveyed the impression to the finger of being a collection of fluid. I requested my friend Mr. Fuge to see the case with me, which he did on the 12th. On the 20th he passed a long trocar and canula into the tumour, and drew off about eight ounces of clear serum. The puncture immediately closed, and her symptoms were at once relieved. On the 25th the operation was repeated, and on July 17 she returned home well. How much agony this woman would have been saved, had she been "speculumised," when she first began to suffer! I am, Sir, &c.

Plymouth. E. T. Roe, M.D.

DIETETIC USE OF COD-LIVER OIL.

[To the Editor of the Medical Times and Gazette.]

Sir,—The accompanying case has been obligingly forwarded to me by Mr. Spender, of Bath, for many years the medical attendant of the late Mr. Barry, the subject of the case.

It was Mr. Barry's own wish that his case should be published in some medical journal for the benefit of others, for he felt that his life had been prolonged by the use of the cod-liver oil, which he took more as an article of aliment than as a medicine.

To enable the profession to appreciate fully the clear and able detail of the case, and of the *post mortem* examinations given by Mr. Spender, it may be useful to premise that Mr. Barry was naturally a remarkably healthy man. In stature he was under the middle height. He was well built, of strong physical organization, and, as he advanced in years, acquired a healthy degree of corpulency.

I had been for years in the habit of visiting the old gentleman as a personal friend, and I saw him for the last time about six months before his death. He had been then living upon the cod-liver oil for about two years, and up to about that time there had been little or no alteration in his appearance. In the summer months he went out occasionally to take the air and transact business in a Bath-chair, and he sometimes took walking exercise on the terrace where he resided without any other support than his ordinary walking-stick. There was, in fact, little or nothing of the decrepitude of old age about him, and his mental energies, which were always above the average, were as vigorous as ever, and he took a lively interest in all public passing events. His senses, too, were all perfect, and he could read the smallest print without spectacles.

But about that time, in September, 1851, he began to break down. His pulse, which, a few months before, was like that of a strong and healthy middle-aged man, was changed in character; and his voice, which used to be strong enough for a huntsman, was become feeble.

I may mention, too, that the portion of egg he sometimes took beaten up in his coffee was but very small, as he himself and his housekeeper also assured me; and the morsel of muffin never exceeded the eighth of an ounce in weight. He did not take those articles every day regularly; sometimes he could not take them at all, and perhaps never oftener than two or three times a-week.

I was often present when he took the cod-liver oil. He always took it floating on a table-spoonful of brandy-and-water, and generally washed it down with a glass of sherry.

With his pint of Scotch ale, he always smoked a pipe of tobacco, and, considering his advanced age and all the circumstances of his case, he slept well, and suffered but comparatively little, except from the feeling of emptiness and exhaustion, which latterly came on with greater severity.

He often expressed a wish to be relieved, yet always submitted himself with pious resignation to the will of Providence, for he was a man remarkably strong in Christian belief and faith, and had a fervent hope of enjoying, on departing this life, the presence of his Redeemer in a happy eternity.

The prolongation of life, I need not remark, is the principal object of the physician's mission, and the discovery of any medicine or article of aliment that can conduce to so desirable an end, cannot fail to be a great acquisition to the Profession, and an advantage to society that cannot be overvalued.

In Mr. Barry's case, it was palpable that life had been prolonged by the use of cod-liver oil as nutriment; and the merit of being the first to give it as an aliment to sustain life, is certainly, so far at least as I know, due to Mr. Spender, of Bath.

The prolongation of life with regard to matters of property, is often of momentous importance to families. There are numerous cases on record, well-known to the lawyers, showing, that if persons had lived but a few hours, or less time, longer, so as to survive others, great advantages would have accrued to their successors.

I could myself mention several cases of the kind, but feeling a reluctance to intrude further on your valuable space, I shall confine myself to giving one instance only.

I happened to have, many years ago, at the same time, two patients who were both on their deathbeds. One of them was a wealthy testator; the other, as it afterwards turned out, was a legatee under the testator's will. They both died the same day, but unfortunately the legatee died a few hours before the testator, and the legacy, consequently, became lapsed. Now, I am satisfied, from the nature of the cases respectively, that if the value of the cod-liver oil had been then known, the life of the legatee could have been prolonged beyond that of the testator, and a poor family would have obtained that which would have made them comfortable for life.

In Mr. Barry's case there are, apart from the effects of the cod-liver oil, several striking features, which I hope will attract the notice of learned and practical pathologists, to whose views on the subject, I am sure, Sir, you would willingly give a place.

The case is, viewing it in all its bearings, perhaps one of the most

curious and interesting upon record, and, as bearing on the properties of cod-liver oil as a singularly nutritious substance, it is probably unique.

I am, Sir, &c.

GARRETT DELLON, M.D. Edin.

5, Spanish-place, Manchester-square.

At the commencement of the year 1840, Mr. Barry, then in his 67th year, experienced a most acute attack of sciatica. The severity of the symptoms soon yielded to the employment of a seton introduced over the track of the nerve; but during the two or three weeks before he consented to the employment of the remedy, the pain was so intense as to compel him to take large and repeated doses of opium. Subsequently to this seizure, he was occasionally liable to milder forms of the disease; these, however, did not recur very frequently, but when they appeared he would resort to the opium. His general health and appetite continued without being much impaired until the beginning of 1849. He then lost not only desire for ordinary food, but all ability to take it. To such an extent had the loathing arrived by the July of that year, that the effort to masticate and swallow any portion was immediately followed by an uncontrollable disposition to vomit. I then advised him to take morning and evening a table-spoonful of cod's-liver oil, mulled wine at midday, a pint of Scotch ale every evening, and also, with a view to lessen the distressing feeling arising from a sense of vacuity, as well as to obviate sciatica, and to procure sleep, an opiate every night. This plan was pursued for about two years and a half, his sustenance during that period consisting almost exclusively of the ingredients mentioned above, with the occasional addition of coffee, with a portion of egg dissolved in it, at breakfast; sometimes a morsel of muffin. His appearance and bulk did not much vary from the date specified (viz., July, 1849,) until the beginning of the present year. About every three or four days he had an evacuation from the bowels of a very extraordinarily natural appearance, bulk, and consistency, when the character of the aliment was considered. Latterly the bowels were unable to act without the assistance of enemas; and four or five months ago the bladder also lost the power of evacuating its contents. About six weeks since, the ability to take the ingredients constituting his sustenance became diminished, he rejected his ale, then his oil, and could only take small portions of wine, or brandy and water. For the last two weeks scarcely anything could be swallowed. The opium was compelled to be increased in frequency to allay the wretched sensation of exhaustion, and at last he died by literally falling asleep and not waking again.

On examining the body, considerable food was found still present, and no unnatural condition or appearance whatever could be detected in the stomach. This organ was not even diminished in size, owing probably to the daily distention by the use of the Scotch ale, a pint of this being commonly taken within a short period. He died on Sunday evening, Feb. 15, 1852, in the 79th year of his age; and the body was examined 48 hours after death.

57, Gay-street, Bath.

THERAPEUTIC ACTION OF VARIOUS MEDICINAL AGENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—A thorough insight into the therapeutic action of different medicinal agents tends materially to augment the real utility of our art, and we have therefore reason to be grateful for any individual contributions in reference to the subject, and ought to endeavour to turn them to practical advantage.

Dr. Handfield Jones's paper on the Action of Antimony, in the *Gazette* of April 10, is interesting as the result of scientific research; it does not, however, seem to tend to such practical results as I consider might be obtained by connecting it with the more empirical investigations which have been already made, and I, therefore, purpose making a few desultory observations on the subject.

Dr. Jones's experiments clearly show that increased action of the mucous membranes results from the administration of antimony, but I cannot believe that on this alone depends the relief which the medicine in question affords in pulmonary inflammation. That antimony produces a peculiar modification of the state of the blood there can be no doubt. Dr. Jones's experiments tend to indicate that such is the case, and such is the opinion of many other physiologists, as well as Dr. Bocker. The simple fact, of the influence of antimony in causing purulent formation, constitutes a practical proof of this. I cannot, however, for a moment admit, with Dr. Jones, that antimony has any power whatever in promoting the secretion of the liver or the kidneys, but, on the contrary, I maintain that the reverse is the case. The emetic action of antimony may cause the discharge of bile in the first instance, if the liver be gorged or the gall-bladder full, but that the secretion of bile is promoted is decidedly not the fact, for I never yet saw a person under the pure influence of antimony, but the pale clayey stools marked a total absence of biliary secretion, and at the same time the renal secretion would also be found more or less completely suppressed. In hospital practice these facts may be readily verified.

My theory of the action of antimony is simply this. That it modifies the constitution of the blood, making it more amenable to the action of the cutaneous and mucous membranes, but at the same time rendering it unfit for renal elimination, and more especially for bilious secretion. But the function of the liver is surely not confined to the mere elaboration of bile; is there not reason to believe that it prepares oily and other carbonaceous matter for the pulmonary combustion? If, therefore, the second hepatic action be arrested, as well as mere secretion, then the usual quantity of fuel will not be conveyed to the lungs, and, the ordinary amount of oxygenation not being required, respiratory action is consequently diminished in force and frequency, to which the atonic state of the nervous system also conduces. Dr. Jones clearly demonstrates the peculiar state of the oily matter in animals killed with antimony, which evidently has a bearing on the question.

In olden times, it was well known that antimony would make monks chaste and pigs fat; the why and the wherefore remain for modern science to resolve. But while we consider antimony as a cholagogue and a diuretic because our fathers did so before us, we shall never know how to use this valuable medicine properly. We cannot at present tell why we give it in pulmonary inflammation, or how it is best to administer it. No one would think of antimony as a remedy in renal disease, though, if there be any foundation for the opinion which I have so briefly adverted to, it may prove a good remedy for albuminuria, diabetes, etc.

I take the liberty of referring Dr. Jones to a paper which I published in the *Lancet* of March 28, 1846, as embracing some curious facts respecting antimony, and I sincerely hope that he will continue his interesting investigations in reference to other medicines.

I am, &c. BUTLER LANE, M.D.

Ewell, Surrey.

CASE OF CONGENITAL HYDROCEPHALUS, WITH BREECH PRESENTATION.

[To the Editor of the Medical Times and Gazette.]

SIR,—In Dr. Lee's "Clinical Midwifery," there are five cases of congenital hydrocephalus given, all of which proved fatal to the mother. As I have lately been fortunate enough to have a successful case of this kind, may I hope you will allow me space in your Journal for the insertion of a few notes of the case.

I was engaged to attend Mrs. C——, residing at Wimbourne; age 38 years, married 17 years; has had eight children. At the last confinement she had twins, and, since then, has miscarried with twins. She is of a spare habit of body, and nervous temperament.

Labour pains commenced about 10 a.m., March 19th, 1852; and I saw her about 2 p.m. The pains were then very feeble and irregular in their intervals.

On examination, I found the os uteri fully dilated, the bag of membranes low down in the vagina, and the presenting part of the child so high up as barely to be reached, and therefore I was unable to determine the presentation.

After waiting till 5 p.m. without any advance, I ruptured the membranes, and an unusually large quantity of liquor amnii escaped. I then found that it was a breech presentation, with the breech still at the brim of the pelvis, and also that a loop of the funis presented; after this, the pains slightly increased, and the labour progressed very slowly; at length, the breech was expelled, and, soon afterwards, the body and shoulders followed, by ¼ to 10 p.m. At this time there was still pulsation in the cord; the head was still detained in the cavity of the pelvis, and the pains almost ceased; in about half an hour the cord ceased to pulsate. I gave a ʒss. dose of pulv. secale, and, in a quarter of an hour, another dose. These had the effect of again exciting the uterine contractions, and of forcing the head a little lower down; but it was still detained, apparently locked between the two spinous processes of the ischia, with the face to the hollow of the sacrum, and it remained so fixed in spite of a considerable amount of traction with one finger in the mouth.

By passing the finger as high as I could reach, I could feel one ear, and perceived that the head was of a larger size than normal; the bones were also slightly movable, and the sutures between the parietal and occipital bones felt distended. I therefore concluded

it was a case of hydrocephalic head, and would require the head to be opened.

I then sent to request the assistance of my friend Mr. Sandford; but, having to send above four miles, a further delay was unavoidable; so, as the patient seemed rather exhausted, I gave her two grains of solid opium, which soothed her very much.

On the arrival of Mr. Sandford, we resolved to open the head at once, and accordingly he passed up the perforator by the side of the neck of the child, through the muscles, and into the skull, behind and below the right ear; immediately some quantity of fluid escaped, I should think nearly a pint, and, on introducing the crotchet, the bones collapsed, and the head was born directly; the uterus contracted well, and the placenta was thrown off, and removed in a few minutes, with very little loss of blood.

The delivery was completed at five minutes to 3 a.m. of March 20th, the labour being of seventeen hours' duration.

The patient was rather low just after the completion of the delivery, but soon rallied, and was fairly comfortable, with a pulse of 104. The uterus remained firmly contracted.

She afterwards convalesced slowly, but without a single bad symptom; she did not require the use of the catheter at all; the after-pains were troublesome for a few days, but, on the twelfth day, she sat up out of bed, and expressed herself as being as well as ever she had felt after any of her labours.

I have seen her this day, being three weeks after her confinement, and she is quite recovered.

In this case, from the distance of the nearest presenting part of the head, and from the contractions of the uterus, especially of the os uteri, which nearly embraced the neck of the child, great care was required on the part of the operator in order to keep the os uteri clear of the point and edges of the perforator, this being the chief difficulty in its use.

Hoping I have not trespassed too much on the space of your valuable journal, I am, &c.

Wolverhampton. C. A. Newnham, M.R.C.S., L.A.C.

IRON SPICULÆ IN THE CORNEA.

[To the Editor of the Medical Times and Gazette.]

Sir,—The difficulty of extracting spiculæ of iron or steel imbedded in the cornea or conjunctiva,—an accident so frequent among engineers, is often so much more embarrassing than one expects, that I am sure those of the Profession who are not aware that the use of the knife may almost always be avoided, will be glad to recollect, that by repeating one of the simplest of their experiments in chemistry,—the immersing a piece of iron in solution of sulphate of copper,—the iron is entirely removed. I usually use the collyrium of one to three grains to the ounce. Although I have mentioned it to many, I never saw the process referred to in print. I was first led to adopt it in my own person when abroad some years ago. While turning a steel cylinder, a point flew off, and stuck fast in the cornea, producing much pain. A professional friend having made several endeavours to extract it, was about to make an incision, when the thought struck me, and, by keeping the eye open in a wine-glassful of the solution, I was speedily relieved from all uneasiness. I am, &c.

Henry Jeanneret, M.D.

12, Finchley-road, St. John's-wood.

MOVEMENTS OF THE HEART.

[To the Editor of the Medical Times and Gazette.]

Sir,—Having dwelt at some length in a recent publication upon the physical diagnoses of the diseases of the lungs and heart upon the recoil theory of the heart's movement in systole—a view universally ascribed on the Continent to Dr. Guthrod—I consider myself called upon to state that the said theory was fully and clearly established nearly thirty years ago by our talented countryman, Dr. James Alderson, in a paper published by him in the *Quarterly Journal of Science* for 1823. As I have had my attention directed to the above fact within a few days only, I take the earliest opportunity of doing this act of justice to Dr. Alderson, whose ingenious view, after slumbering for nearly thirty years, has now found many able advocates in Germany.

Whether Dr. Gutbrod at any time saw the original paper, or worked out the theory from the independent reasoning of his own brain, I am not in a position to decide. I would simply in this communication give honour to whom honour is due, by showing to whom the ingenious theory of the motion of the heart is really to be ascribed. I am, &c.

23, Finsbury-square. Herbert Davies.

THE FRACTURE SWING.

[To the Editor of the Medical Times and Gazette.]

Sir,—Owing to some mistake, I observe that the smaller figure in the engraving attached to my communication upon the ball and socket swing for fractures of the leg, has been left undescribed. I have, therefore, to state, that it represents the top of the arch, as constructed when the frame is made in a portable form.

Since my former letter was sent to you, I have suggested to the maker, (Mr. Bigg,) that the beam should be constructed of light iron pierced with the necessary holes, and that the centre pin should be provided with a hook at the lower extremity, by means of which the beam is attached to it.

The pulleys are connected with the beam by means of a letter S hook.

The swing thus formed is now being more fully tested at Guy's and King's College Hospitals. Your early insertion of the above will oblige Yours, &c.

Rye, Sussex. Alfred Roberts.

THE GRADUATES' COMMITTEE OF THE UNIVERSITY OF LONDON.

[To the Editor of the Medical Times and Gazette.]

Sir,—Will you permit me to ask the Honorary Secretary of the Graduates' Committee of the University of London to publish, for the benefit of your readers, the numbers of graduates in arts, laws, and medicine respectively, who have attended each Committee meeting during the past twelve months, giving to any one the higher title only when he may have two.

The graduates are now informed that a greatly increased effort is being, or about to be, put forth for the coercion of the Senate. The Committee nominally consists of thirty-six members, but only a mere fragmentary number attend the Committee meetings, and these, therefore, constitute the real Committee.

It is commonly reported that the graduates in laws and medicine take very different views as to the means to be employed in this struggle; and, since the graduates in medicine have a greater stake in the issue than those in laws, it would be satisfactory to learn if the proposed coercive measures are supported by those graduates in medicine who are now members of the Committee.

The movement will succeed, doubtless; but it is the opinion of many, that the disrespectful expressions and efforts which have been employed by the Committee will greatly delay the desired consummation. I am, &c. M.B.

London.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

John Bishop, Esq., F.R.S., F.R.C.S. Eng., President, in the chair.

Mr. Canton brought under the notice of the Fellows of the Society

A PECULIAR SYMPTOM OF RHEUMATIC OPHTHALMIA,

which he had so frequently had occasion to notice associated with this complaint, that, in cases the nature of which otherwise might have presented difficulty in their diagnosis, had been rendered easily distinguishable by its presence. He alluded to a peculiar white deposit collected at the internal or external canthus of the lids. It is often abundant, and in mild attacks but scanty, and often exists where there is no deposit in the urine; but in proportion as this secretion, in many cases, becomes charged with the lithates, so will the white deposit be lessened in amount at the canthi. Sometimes it is associated with slight pains in the loins, limbs, or the larger joints, but of which the patient makes no particular mention; while at other times the pain may be more severe, and distinctly articular. It was, however, in those cases more particularly where the affection was not especially marked as one of a rheumatic character, that this symptom, Mr. Canton believed, would be found valuable, as indicative of the real nature of the complaint, and which pointed out, at the same time, the advisability of employing those medicines which are generally so beneficial for rheumatism elsewhere situated. Mr. Canton had had cases

under his care, where the symptom referred to was present, where other rheumatic signs were absent, and which, resisting other treatment, had then been benefited by the exhibition of alkalies with the tincture of aconite and colchicum wine.

PRESERVATION OF PATHOLOGICAL SPECIMENS.

Mr. B. W. Richardson recalled the attention of the Society to his new mode of preserving pathological specimens in antiseptic gases. Early in last session he (Mr. Richardson) had exhibited to the Society a specimen that had been kept for a long time in arseniuretted hydrogen gas. The poisonous nature of this gas had, however, led him to discontinue its use, and he had since used, with great success, 1st, simple nitrogen; and, 2ndly, chloroform vapour, the antiseptic power of which had been shown by Robin and Dr. Snow. The specimens exhibited were four in number. The original one, in arseniuretted hydrogen; two, (portions of an ulcerated lung,) one in nitrogen, the other in chloroform vapour; and a uterine tumour, in nitrogen. The portions of lung had been preserved for seven months, and none of the specimens had undergone the slightest change, either in colour or consistence. The mode of using the nitrogen gas was very simple: the preparation was first fixed in the bottle, which was then filled with water through a hole in the cork, and the gas introduced by displacement under water. With chloroform, it was only necessary to drop a few drops of the liquid into the bottle while held in warm water, closing the bottle as soon as the vapour began to pass over. The mouths of the bottles must be perfectly sealed. Mr. Richardson was of opinion, that the cause why these specimens were thus preserved rested in the simple fact, that they were removed from the influence of oxygen; and he believed that pure nitrogen, used in the manner described, would be found to surpass every other process for preserving animal food for dietetic purposes.

Mr. Barlow read a paper

ON FATTY DEGENERATION.

The author began by insisting on the great importance and extent of the whole question of fatty degeneration, which had naturally interested so many observers, from the vast number of pathological consequences which it, and it only, could explain. The subject was to be viewed comprehensively, and as a whole, and not as illustrated by any particular organ or part. It could not be separated, unless by the imagination, from the yet larger question of atrophy, of which, indeed, as Mr. Paget had said, it was a manifestation. Fatty degeneration was the consummation and result of atrophy—a word which should be used as denominating the slightest impairment of nutrition, as well as that obvious wasting of parts which paralysis, phthisis, and many chronic maladies presented in forms more or less striking. Seeming hypertrophy and real atrophy co-existed; muscular fibres might seem enlarged to the eye; but, viewed with the microscope, might be found degenerated into fat, as had been long shown in reference to the hypertrophied heart, and lately by Mr. Hancock in relation to the (so-called) hypertrophied bladder. Bulk was in these cases no measure of power, but just the contrary. The author thought that the general subject of fatty degeneration might be best pursued by looking at the conditions known to be essential to perfect nourishment, and then fairly tracing the results of their failure. The degeneration might be produced—first, by a wrong or defective state and composition of the blood; second, by an insufficient supply of blood; third, by a deranged or obstructed influence of the nervous system; fourth, by an imperfect, unhealthy, or declining state of the part to be nourished. These conditions were, in every respect, the reverse of those which Mr. Paget had specified as most important to healthy nutrition. The author treated these points in detail, and the following is a mere outline of his remarks:—

I. The state of the blood in reference to nutrition had been noticed by Harvey in an emphatic manner. It was modified by age, and varied by disease to a remarkable extent. It had been found deficient in corpuscles, in anæmia, (or spanæmia, as Simon termed it,) hæmorrhage, and some cases of granular degeneration of the kidney; but much on this subject was to be inferred from reasoning on certain obvious conditions of the system; nor could it be expected that analysis, however ingenious and subtle, could be expected to cope with half the difficulties of the question. The blood might be said to grow old; he believed the climacteric disease, as Sir Henry Halford had denominated it, to be a mere sign of degeneration—oftentimes of fatty degeneration, or that chiefly. This kind of decay happening late in life, and gradually loosening its tenure, could hardly be called morbid or abnormal, being altogether as much in the order of nature as the fading of a leaf at the autumnal season. But decay was impatient, and anticipated time: premature degeneration would occur from various general and local pathological states, in many whereof the blood was to a certainty most seriously involved. The observations of Dr. Ormerod and Dr. Quain upon the general relation of wasting maladies to this destructive process, as well as those made by Mr. Gulliver on its occurrence in various parts and states, were referred to at length. The author knew, from his own observations, the vast practical bearings and high interest of this part of the subject. Fatty degeneration was very frequently the most perilous complication, and it was necessary to watch for, and if possible to detect it. Persons sometimes during chronic maladies would turn pale, and expire in a moment: the heart was at fault; degenerated to the utmost, it could act no more. It was to be suspected that the hæmorrhage of disease, as well as artificial losses of blood, had very often assisted in inducing, and quite as often greatly aggravated, this downward change. Cases of fatty degeneration had occurred at six and eight years of age, and Dr. Snow Beck had observed an instance of degeneration of the small cerebral blood-vessels in a child aged one year and seven months; he had detected minute granules in their coats, but did not consider it certain that they were oil-globules, as they had not been tested by dilute hydrochloric acid and ether.

II. The question of inadequate supply of blood was, for the most part, inseparable from that already treated of. Pure anæmia could never last long; abstraction of blood even, if too frequent, led to the spoiling of what remained; yet some practitioners had bled the palest and most bloodless, on the bare imagination of inflammatory action: but not thus could be remedied confirmed anæmia, or atrophy repaired, or degeneration arrested. The changes throughout the arteries and their branches, which led to local obstructions of the circulation, needed fuller inquiry; those obstructions of the heart, as had been well shown by Dr. Quain, acted in the manner of partial ligatures, and led to local anæmia and decay, or they might proceed the length of completely cutting off the supplies of a part. Whether narrowing of an artery would cause local atrophy or death, depended on the condition of the neighbouring vessels, which might be too degenerated themselves to enlarge and compensate for the withdrawn supply. The same remark applied to ligatured arteries in cases of aneurism. Arterial degeneration might be so extensive, and especially if the heart were fatty and feeble, as to prevent the circulation being carried on. The peculiarity of the cardiac circulation, noticed by Mr. Swan, and remarked on by Dr. Quain, as favouring fatty degeneration of the heart, was observed upon. There was no free communication between the branches of the coronary arteries, and the conservative influence of anastomosis was absent. Harvey had dwelt most fully on local modifications of the general circulation. The author thought that some local deaths which had been referred to obstructions of an artery or large branch of it, had really depended on the arrestation of the streamlets in its smaller ramifications. All general and local defects of circulation were to be considered perilous in proportion as the general nutrition might be impaired.

III. The question of nervous influence, in relation to the failure of nutrition and fatty degeneration, was extremely complex, but there could be no doubt whatever that its derangement or withdrawal had a large share in the production of atrophy and its results. Rostan, Lallemand, and others, had referred to cases of softening of the brain, which they partly attributed to grief and anxiety. But though nothing was more certain than that the mind so deranged the vital function as to waste the body and "fret it to decay," there was nothing harder than to measure its influence,—to separate it from other simultaneously acting causes of destruction, or to define the exact part which it played among them. The withdrawal of nervous influence by mechanical means, such as those seen in the paraplegia of disease or fracture of the spine, was to be considered by itself; the mind could not reach the affected parts; volition and emotion were withdrawn; and the atrophy which followed was to be explained more readily than that which happened in parts yet open to mental impressions. The state of the mind often injured nutrition, in an indirect manner, by withdrawing the body from those exercises and diversions which constituted the main sources of its vigour; by depressing and interfering with the heart's action, so that the blood was circulated with insufficient frequency and force; by modifying the respiration so extremely that the oxygenation of the blood was less perfect than it should be; by seriously interfering with the digestive function, the disorders of which spread through the body; and, oftentimes, by banishing or breaking the sleep, which had been called so finely, "chief nourisher in life's feast;" but he doubted not that, in many cases, from what might be observed of the effect of the emotions upon different secretions in time of health even, that there was frequently, besides all this, an indirectly depressing influence exercised by the mind, both

locally and generally, on the function of nutrition; and he thought it probable that it might at times aid greatly in leading to degeneration, and in aggravating it where it already existed. But he would refer to some observations by Mr. Paget, in reference to matters more or less touching this subject; and also to Dr. Holland's chapter, contained in his "Notes and Reflections," on the effect of attention on the bodily organs.

IV. The fatty degeneration of parts, as affected by general and local defects of assimilation, was one of the most difficult yet important divisions of the subject. Each tissue might be termed a centre of appropriate and discriminative nutrition. It had a special life of its own, though that were in the circle of, and dependent on, the general vitality. It had, doubtless, hereditary strength or weakness, such as affected the entire organism. It had its own circulation and its own nervous influence, liable to especial impairments; it might be subject to premature death, or be found, when the body as a whole had died, with a structure perfect to the minutest line. The healthier a part was, the likelier was it so to remain; and the converse was certain. The least atrophy was an approach of death, no matter whether it concerned a fibre, or the complex anatomy of all the frame. But mere atrophy was recoverable; and, though parts of an organ had degenerated irrecoverably, the surrounding structure might be restored to vigour, and compensate effectually for the loss sustained. The only part in a degenerated condition which could be watched by the eye, was the cornea; and a case of great interest had been communicated to the author by Mr. Charles Simpson, in which the arcus senilis, which had been both well and frequently observed, had disappeared. He agreed with what Dr. Quain had written respecting the treatment of the degenerated heart, and the hope, in some cases, of arresting the changes in it. Reparation there could not, of course, be seen; but the undestroyed fibres might enlarge and strengthen, and its beats become firmer, and its sounds more audible. In the young, the middle-aged,—nay, in some quite old,—in all, indeed, who had much sound structure left,—fatty degeneration might probably be counteracted by a new vigour infused into the body, and by certain changes in the atrophied tissues which adjoined or bordered on those which had perished. The author adopted Dr. Quain's theory of the process whereby fatty degeneration was effected, and referred to a suggestion made by Dr. Williams respecting its nature. Dr. Quain had found, by accident, changes produced in the hearts of the dead similar to those which often happen in the living under circumstances of low vitality, of a feeble or deficient circulation, of impaired nervous influence, of structure long damaged by insidious atrophy. It was the power, or rather the combined powers, of life, however vague we might term the expression, which preserved us in integrity, and hindered the changes which implied death. An extract was read from Dr. Quain's memoir touching this point. How long the tissues were preserved healthy in some cases, was not less remarkable than their premature decay in others. Mr. Canton had given him a minute description of the state of the heart-fibres of a man aged 103, which was drawn up by Dr. Quain after most careful examination; and it was only in a spot or two, and to an inconsiderable extent, that any of the fibres were found degenerate; but what was most interesting, viewed in connexion with this state of the heart, was, that the cornea was free from the arcus senilis, and, microscopically examined, only presented a very few fat-granules scattered here and there. The specimen was, through Mr. Canton's kindness, placed before the Fellows, and they might compare it with another, in which the arc had been obvious, showing the true structure of the cornea thickly crowded with countless fat-granules. The author referred to some recent observations made upon the subject of fatty degeneration, but especially to those which had been made respecting the fibres of the uterus, and the vessels of the placenta. He also directed attention to a most interesting contribution of Dr. Dittrich, who had found a fatty degeneration of the vessels of the lungs in some cases of pulmonary apoplexy, similar to that already discovered by Mr. Paget (and to which the author had, on a previous occasion, specially called the attention of the Society) in those of the brain. Dr. Kirkes had kindly given him an abstract of the principal conclusions. The most important was, that there was "a fatty metamorphosis of the walls both of the larger, and especially the smaller and smallest vessels." This occurred in the "large majority" of cases of pulmonary apoplexy. Dr. Charles Shearman had found most distinct groups of fat-granules lying in the substance of the coats of a small vessel of a degenerated heart. The "diameter of the vessel was $\frac{1}{1\,1\,1\,4}$ inch." The author had the opportunity of observing it. Marked degeneration of the cerebral blood-vessels, great and small, was found also. The author, after taking a general view of the important researches of various inquirers, asked the Society whether a grand advancement had not been made in a subject which bore largely and intimately, not only on the science but on the practice of medicine?(a)

Dr. Daniel spoke in terms of great praise of Mr. Barlow's paper, but regretted it had been curtailed at a part where facts would have been adduced, showing that intense mental anxiety, etc., may cause a disordered condition of the blood, and thus induce the degeneration of the heart, and its sudden rupture, of which he had seen two or three examples, the result of melancholia, caused by mental anxiety.

Dr. Handfield Jones referred to two facts as bearing on the question of fatty degeneration, the one being, that a certain combination of oil and albumen is essential in every act of nutrition; and the other, that the change in fatty degeneration consists in the separation of the oil from the albumen. With respect to the degeneration itself, he thought it doubtful whether it consisted of an actual conversion of the tissue into fat, or of the deposit of fat in the place of the wasted or atrophied fibre. He himself inclined to the latter opinion, and thought that facts and experiments tended to confirm that view.

Mr. Richardson joined with Dr. Daniel in his regret that the cases in which this degeneration had been brought on by mental anxiety, etc., had not been given by the author, and he inquired whether that result was caused directly or indirectly, as by the disordered state of the primæ viæ, and the altered condition of the organs of digestion, thus set up. He knew that many persons in cases of hypochondriasis seek at once for signs of fatty degeneration of the heart. Mr. Richardson then referred to the question as to the propriety of bleeding in all cases of apoplexy, and said he was satisfied that in many instances of what is termed pallid apoplexy, death is caused by failure of the central organ of the circulation. He was called lately to see an old lady who had fallen down insensible—in a fit, as the bystanders said, and they were all exceedingly anxious she should be bled. This he opposed, and finally, but not without great opposition, had some brandy given to her, which afforded great relief.

Dr. Basham said, that the question was in some measure so new as to render it difficult to collect one's thoughts, so as to examine the subject in a serviceable manner. There was one point, however, as to its being a positive decay, so that they might arrive at a distinction between that which is absolute disease, and perhaps curable, and that which is real decay and incurable. He then commented on Dr. Handfield Jones' remarks, and observed, that zoo-chemists were aware that the fibrous exudations of inflammation and pus-corpuscles contain a large amount of fat, showing the important part that element plays in morbid processes, and thus we may not be unprepared to see hereafter, that the conversion of tissues into fat may be traced by a consecutive chain of phenomena.

Mr. Henry Lee observed, with reference to the question mooted by Dr. Handfield Jones, as to whether fatty degeneration is an absolute conversion of the tissues into fat, or merely a deposit of fat in an atrophied part, that he had lately examined some tumours from the neighbourhood of the rectum, which were removed on the supposition they were malignant, and which he had found were almost entirely fat, which had been morbidly deposited, and was not a mere conversion of tissue.

Mr. Dunn would like to ask Mr. Barlow one question, Whether he had had an opportunity of carefully investigating the actual condition of the blood in cases of fatty degeneration? Pathologically considered, the subject was one of great interest and importance. For himself, he had been led to embrace the views expounded by Dr. Williams in such cases, both in reference to the products of local inflammations and to the active agency at work in the scrofulous and tubercular diathesis, in the development of tubercle itself in phthisical subjects.

Dr. Ryan suggested, that as Dr. Quain was present, and he had paid especial attention to this degeneration, he would perhaps be kind enough to furnish the Society with some information on the subject.

Dr. Quain said, that he could not hesitate to reply to the call thus made on him, although he came there rather as a visiter in search of information. In that respect he had not been disappointed. He had listened with great satisfaction to the interesting and suggestive paper which had been read, and to the important and valuable remarks made by the gentlemen who had spoken subsequently. He had so fully entered on this subject elsewhere, that he would not then go into the question at any length, but would briefly refer to some of the observations which they had heard that evening from others. The relation of mental affections to this disease of the heart was one of great interest. He had met with several cases of dege-

(a) Some portions of this highly interesting and valuable paper were, of necessity, read in abstract, its great length precluding the possibility of reading the whole at one sitting, if any discussion were to follow.

neration of the organ in individuals who had previously suffered much anxiety. In three instances, the degeneration was such as to have led to rupture of the heart, so that the sufferers may be said literally to have died of a broken heart. Mr. Richardson's observation, that mental anxiety leads to disturbance and derangement of the nutritive functions, affords no doubt a correct explanation of the source whence this impairment of structure proceeds. It is also worthy of remark, that this state of heart is often associated with a peculiarly irritable state of mind—a state probably due to an impairment of other structures as well as of those of the heart, and to the influence which the organ exerts over the comfort and well-being of the individual. Then, again, the pathological cause of, or the condition on which this state of heart depends, is one of great interest and importance, in connexion, of course, with the treatment to be adopted. There was no doubt that Dr. Handfield Jones was correct in some of his remarks. The combination of oil with albumen was a primary step in the process of nutrition, and the presence of oil with albumen in fatty degeneration was, so to speak, the evidence of final decay. These combined elements enter the blood from the chyle vessels. In this fluid they soon disappear. They enter under the influence of what we call the organizing power into the composition of the tissues and textures. Here, under the continued influence of this power, they undergo changes, they are removed, and a fresh supply afforded. But when this influence is weakened, this process of supply and removal is stopped, and the tissues return to their primitive form. He referred to his communication in the "Transactions" of the Medico-Chirurgical Society for a full detail of the mode in which this degeneration occurred. No better examples of the truth of this proposition could be offered than those mentioned by Dr. Basham, in which, in effusion of fibrin and pus, fat abounded. Substances such as these, the elements of which were held together by the feeblest affinity, soon passed into a state of degeneration. He looked with more confidence than had been expressed by some of the speakers to the means capable of arresting this process of decay. He had concluded theoretically, that fatty degeneration was the result of impaired nutrition and subsequent decay; and experience, by showing him, in several instances, how great was the benefit resulting from the means by which the only condition could be improved, and the other arrested, had confirmed the theory. Of course, so favourable a result must be looked for in cases of premature decay, rather than in those which were met with in advanced life, and in the ordinary course of exhausted nature. The fact which the researches of M. Kilian had brought to light, and those of Mr. Rainy had confirmed, viz.—that the fibres of the uterus, after delivery, underwent a fatty degeneration, and that new fibres were developed—showed that there was much ground for believing that the process was not one of absolutely irremediable destruction.

Mr. Barlow said, in reply, with respect to mental anxiety as causative of fatty degeneration, that the subject of mental affections as the origin of disease, was one of the most difficult of all questions. The evidence was very clear to prove its influence as causative and aggravative of disease, but it is very difficult to prove its direct action. Mr. Paget, in his College lectures, had spoken of the influence of nervous disorders on nutrition, and if this be correct,—of which there could not be a doubt,—its influence in inducing atrophy will be evident. The history of a case will generally show, that grief or some other depressing influence was connected with the origin of the complaint. The depressing passions exert a very injurious influence on respiration and circulation, and produce a disordered state of the system. If any one will carefully watch himself, he will readily come to the conclusion, that mental influences greatly disturb nutrition. With respect to the question of blood-letting raised by Mr. Richardson, he believed that the facts connected with fatty degeneration, would exert more influence on it than any other cause; and as regarded cases of apoplexy, or cases so recorded, he considered that very many so-called, were in reality instances of disease of the heart, and nothing was so likely to cause them to end fatally as bleeding. In real apoplexy, blood-letting is not practised, as was formerly the case, for it is frequently indicative of a tendency to decay, with fatty degeneration, and the arcus senilis,—a sign which he (Mr. Barlow) considered to be very diagnostic of that degeneration. He had not examined the blood as Mr. Dunn had inquired, but authors had described such changes in the constitution of that fluid as must exert a greater or less influence on nutrition. He (Mr. Barlow) did not possess any facts bearing on the remarks made by Dr. Handfield Jones. He had fully adopted the views promulgated by Dr. Quain in his admirable paper published in the *Medical and Chirurgical Transactions*. The conversion into fat was, he thought, both a physical and a chemical change, and may occur after death, or while life is departing.

MEDICAL NEWS.

Royal College of Surgeons.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 16th inst.:—

Bolton, Robert Thorley, Hexham, Australia.
Desplan, Henry, Bath.
Kirby, Edmund Adolphus, Hamstead-road.
Lawrence, Henry John Hughes, Carmarthen.
Macnamara, Francis Nottidge, Uxbridge, Middlesex.
Merry, Francis William, Shottesham, All Saints, Norfolk.
Montgomery, James Barclay, Penzance, Cornwall.
Pickstock, George N., Belize, Honduras, West Indies.
Rogers, H. J., Peninsular and Oriental Steam-packet Service.
Spender, John Kent, Bath.
Stocker, Alonzo Henry, Grove-hall, Bow, Middlesex.
Wilkinson, Edwin Adolphus James, Birmingham.

At the same meeting of the Court, Messrs. William Mackay Ogilvie and Francis Yeates Toms passed their examinations for naval surgeons. These gentlemen had previously been admitted members of the College, their diplomas bearing date respectively July 26, 1847, and August 14, 1848. Mr. Toms having been appointed to H.M.S. North Star, proceeds in search of Sir John Franklin.

Graduates for M.D., University and King's College.—April 15, 1852:—

Allen, Christopher A., Cork.
Brown, Philip, Durham.
Crosland, George, Yorkshire.
Elliott, Ernest, Portsmouth.
Jones, John Dalston, London.
Molloy, Robert, Pentonville.
Popham, William Home, London.
Richards, Owen, Cardiganshire.
Ross, James, Elgin.
Young, James William, Co. Meath, Ireland.

Military Appointments.—23rd Foot: Staff-Surgeon of the 2nd class, Richard Gamble, M.D., to be surgeon, vice Bradford, promoted on the staff. 35th Foot: William George Clarke, gent., to be assistant-surgeon, vice Fairbairn, promoted on the staff. Hospital Staff: Surgeon Edward Bradford, from the 23rd Foot, to be staff-surgeon of the 1st class, vice Andrew Foulis, who retires upon half-pay. Assistant-Surgeon William Home Fairbairn, M.D., from the 35th foot, to be staff-surgeon of the 2nd class, vice Gamble, appointed to the 23rd foot. *Memorandum.*—The removal of Assistant-Surgeon John Knox Leet, from the 85th Regiment to the 10th Foot, and the appointment of Mr. William George Clarke to the assistant-surgeoncy of the 85th foot, on the 26th March, 1852, have been cancelled.

Medical Appointments and Vacancies.—The office of house-surgeon and dispenser to the Portland-town Free Dispensary is vacant, salary 65*l.* a-year, with an unfurnished residence. Candidates must not be more than forty, and duly qualified to practise. No private practice allowed, so that a legally-qualified medical man is expected to do everything but lodge himself, and give up his whole time to the charity, for 65*l.* a-year. *Proh pudor!* The pay is much worse than that of a banker's junior clerk. Medical officers are required for the Tamworth union; one for the Fazeley district, salary 50*l.* a-year, with 10s. for each midwifery case, 1s. and 1s. 6d. for vaccination, and the usual Poor-law extras; and one for the Kingsbury district, salary 26*l.* 12s. a-year, with the same extras as for Fazeley. Leeches to be provided by the medical officers. Date of election, the 24th inst. A house apothecary will be elected on the 13th of May for the Dorset County Hospital, Dorchester. Testimonials on or before the 28th inst. Candidates must possess the double qualification, and be unmarried. They must also engage for three years, if their conduct be approved. Salary 50*l.* a-year, with 10*l.* annually as Secretary. A house-surgeon is wanted for the Liverpool Royal Infirmary; board and lodging, but no salary. Candidates must be M.R.C.S. Testimonials on or before the 28th; election next day. A resident house-surgeon and dispenser is required for the Milton and Gravesend Dispensary, salary 75*l.* a-year, with furnished residence, and 17*l.* a-year allowed for coals, candles, washing, etc. The double qualification required, and the person elected is not permitted to practise within three miles of Gravesend, for one year after resigning the office. Election, 28th of May. At the Rotherham Dispensary, a medical officer is wanted, salary 120*l.* a-year, with house free of rates and taxes. One qualification required. Election, 1st of May. House-apothecary is wanted for

Addenbrooke's Hospital, in Cambridge. Election, 26th of May. Salary, 86*l.* a-year, with board and lodging. Testimonials on or before the 21st.

Obituary.—On the 15th inst., at Andover-lodge, John Burton, Esq., late of the medical staff of the Madras army.

Her Majesty's Levee, of the 21st, was attended by the following members of the Profession:—Dr. Ferguson, Dr. Ashley, and Mr. Erasmus Wilson. The following presentations took place:—Dr. Rutledge, by Lord Rosslyn; Dr. J. B. Thomson, by Lord Malmesbury; Dr. Wylie, by Mr. J. C. Herries.

Statistical Society of London.—Lieut.-Col. W. H. Sykes, V.P., in the chair. Dr. Guy read a paper on the Vital Statistics of Chittagong, Bengal, by Assistant-Surgeon Bedford; and Mr. Farr brought before the meeting a notice of the cholera in England in 1848-9, the discussion on which was adjourned to the next meeting of the Fellows on the 17th May.

City Orthopædic Hospital, Hatton-garden.—At a recent meeting of the officers and governors of this Institution, the Report stated, that the establishment was prospering greatly, and that altogether 582 patients had been cured, or were still under treatment. The first course of lectures on Orthopædia was concluded on the 17th inst.

Medical Society of London.—The Lettsomian professors appointed for the session of 1852-53 are, Dr. Murphy, who will deliver some lectures on points interesting in midwifery, and Mr. Pilcher, whose lectures will embrace some subjects of importance in the science of physiology.

Society for Relief of Widows and Orphans of Medical Men in London and its Vicinity.—The sixty-fourth anniversary of the foundation of this Society was celebrated last Saturday, the 17th instant, at the Freemasons' Tavern. Sir Charles M. Clarke, bart., the President, in the chair, the usual loyal toasts having been given, and "The Army and Navy," coupled with the honoured name of Sir James M'Grigor, the Chairman proposed "Prosperity to the Institution," and regretted that the sums granted to the widows and children of members were so small; still the Society had gone on ever since its foundation, increasing steadily though slowly in its numbers, in the amount of its capital, and in the number and amount of the grants for relief. He congratulated the Society on their having now obtained a local habitation at the house of the Royal Medical and Chirurgical Society. Mr. Hedgson proposed the health of the President, Sir Charles Clarke, to whose professional and personal worth he paid a well-deserved tribute of praise. The President expressed his very great regard for the profession to which he had so long belonged, and his especial gratification at meeting the members of this Society on these occasions, and at the Courts over which they had done him the honour of electing him to preside. Mr. Ware assured the members of the interest which the Court of Directors took in the business entrusted to their management, and of the scrupulous regard which was paid to the due administration of the funds. Mr. Stone stated, as an instance of the benefits conferred by the Society upon those who needed its assistance, that a widow was receiving 100*l.* a year for herself and her six children, though her husband had subscribed only ten or twelve guineas during his lifetime. Dr. William Merriman, the acting Treasurer, stated, that a most gratifying donation had been received, namely, 50*l.*, which one of the widows, shortly before her death, had desired might be given to the Society, from a small fund in her possession, as a mark of her thankfulness for the relief which, for many years, she had received from its funds, and which had enabled her to struggle successfully with very serious difficulties. Mr. Walsh, the Secretary, stated that the Society had gradually overgrown the arrangements which had hitherto sufficed for conducting its operations. This had long been partially felt, but had now become quite apparent. He trusted that on Wednesdays, the days of his attendance at the Society's rooms in Berner's-street, he should be honoured with inquiries of many members and others, to whom he could give abundant information as to the Society's usefulness. The subscriptions received amounted to 211*l.* 8s.

Oxford Medical Dispensary and Lying-in Charity.—At the Annual Meeting, recently held in the Town-hall, the Principal of Magdalen Hall in the chair, the Report was read, to the effect, that on the 1st of January, 1851, there were 65 patients on the books, and that 1241 had been admitted since, the total being 1306. Of these, 1022 cured, 65 dead, 145 relieved, 11 sent to the Infirmary, 9 to the parish, and 54 remaining on the books. In addition, there were 158 midwifery cases. Admitted since the foundation of the dispensary in 1807, medical cases, 38,857; midwifery ditto, 5543; total, 44,400. The receipts for the past year were 305*l.* 14s. 2d; the credit side included 80*l.* retained for investment, and a balance of 4*l.*, after payment of the House Surgeon's salary, and of other incidental expenses. The Institution is well supported.

Progress of Epidemics.—By the latest reports it is stated, that yellow fever is very severe at Rio de Janeiro among the shipping, and there have been a few fatal cases on shore. Owing to this, the Tay, Royal mail-steamer, was placed in quarantine at Teneriffe and Lisbon. The crews of foreign vessels are suffering severely. The fever has almost left the Cape de Verde Islands. The small-pox has broken out on board Her Majesty's steam-sloop the Sphinx, Commander Shadwell, on the coast of China, and several men and officers, including both lieutenants, are laid up with it. The gun-room steward has died from the endemic. This disease has also shown itself on board Her Majesty's steam-frigate the Dragon, in the Tagus. The clerk has been attacked by it, and sent to the Naval Hospital at Lisbon.

Poisoning by Laudanum.—Another of these cases was lately made the subject of inquiry before Mr. Baker, the coroner, at Bethnal-green. It appeared from the evidence, that the deceased, an infant nine months old, was put out to dry-nurse, in consequence of its father being seized with small-pox. It was in good health, but restless at night, and the nurse, anxious for a good night's rest, gave it some laudanum at 11 p.m., and another dose at 3 a.m. the next morning. Death followed the exhibition of the poison. The verdict was, "That the deceased died from the effects of an excessive dose of laudanum, administered as a composing draught." The coroner, at the request of the jury, admonished the nurse's two sisters, for having given the laudanum without having obtained medical advice, and observed, that it was out of a merciful consideration of the jury that they did not return a verdict of manslaughter. True mercy and justice would have been administered had such a verdict been returned. Some cases of severe punishment are required to put a stop to the baneful practice pursued by many nurses, of insuring themselves good nights' rest by half or wholly poisoning the helpless babes entrusted to their charge. The restlessness exhibited by the babe is easily accounted for; it was removed from the maternal care—in all probability, from the breast—and entrusted necessarily and properly to hirelings, who undertook to bring it up by hand, and gave it food which more or less disturbed the stomach; for, as all who have had anything to do with dry-nursing infants are well aware, there is scarcely anything so difficult as to find articles of food other than the mother's milk adapted for an infant's stomach. Instead of remedying this by using other aliment, the infant was poisoned, not by one, but by a repeated dose of a powerful narcotic. Laudanum ought to have been included in the Sale of Arsenic Act.

The Woolrige donation fund for the Free Cancer Hospital is now completed. The money thus raised is to be set apart for the maintenance and treatment of in-door patients exclusively.

DEATHS *in the Metropolis for the week ending Saturday, April* 17, 1852.

ORIGINAL LECTURES.

CLINICAL LECTURE

AT

King's College Hospital.

By WILLIAM FERGUSSON, Esq., F.R.S.,

Professor of Surgery in King's College, London, and Surgeon to King's College Hospital, etc.

CLEFT PALATE.

Gentlemen,—We have lately had in the house a number of cases which well deserve some especial notice at my hands in my clinical observations to you. Some of them are important, owing to their ordinary character, while others no less claim your attention because they are chiefly examples of disease and treatment not frequently coming under your notice. To the latter class of cases I shall this day draw your particular attention. You are aware, that within the last few weeks we have had some cases of malformation of the palate, which have excited some interest in our minds, and the more so as you know I have paid considerable attention to the subject of these malformations—a subject, indeed, which has of late years increased both in magnitude and in interest. It would scarcely suit the present lecture were I to dwell at length upon the history of this malformation; but I may say, that the subject of cleft palate was at one time almost out of the field of surgery. It is only within the last twenty-five years that it has been prominently brought forward, and has so much increased in interest as to be looked upon most carefully by those surgeons who were anxious to remedy malformations of the kind. It may, previous to that time, be said to have been beyond the aid of surgery. The only plan which surgeons could devise as of any utility, was to put an artificial palate into the roof of the mouth; and, indeed, this department was chiefly in the hands of the dentists. Since this period, however, it has been found out, that, by a surgical operation, such a modification of the parts may be brought about, as to insure a closure of the cleft in the soft palate. Like as in other important discoveries, it may be said that an accident almost led to this discovery in surgery. A medical student in Edinburgh who was subject to this malformation, went over to Paris at an advanced stage of his pupilage, to finish his professional studies. While there, he saw the celebrated French surgeon Roux, who, in conversing with him, discovered the deficiency, and proposed to endeavour to effect a cure by some operative proceeding. This was readily assented to. Now, Roux thought of treating the fissure in the soft parts of the palate just in the same manner as surgeons were in the habit of operating for a similar condition of the upper lip. He did so in this case, and, the operation succeeding, the patient returned to his native country so much improved, that his friends certainly did not know him by his voice. This, I believe, was the first case ever performed. It was afterwards performed by Graefe, of Berlin, Warren, of Boston, and many others.

During the last twenty-five years, various modifications of this operation have been recommended and adopted by several surgeons, in accordance with their own particular views of treating the affection, or with the peculiarities of each case. However, with the exception of the cases occurring in the practice of Roux, and of one or two surgeons in America, there has not been very great success with this operation. Roux is understood to have operated on upwards of one hundred cases, and to have succeeded in one-third of them; but the American surgeons, Mason Warren and Mûtter, have succeeded better. In this country, it may with truth be said, that the operation had almost fallen into oblivion.

In my younger days I saw several cases of cleft palate in Edinburgh, where operations were attempted, but they turned out very unsatisfactory. The late Mr. Liston very rarely performed the operation; even he, with all his great skill and manual dexterity, was very unsuccessful in these proceedings. About seven years ago a new impulse was given to the subject, in consequence of some views of my own having been offered to the Profession through the medium of the Medico-Chirurgical Society, who honoured a paper of mine, on the subject of cleft palate, with a place in their Transactions; and subsequently there has been more written about the subject than at any previous period. The peculiar and important features in my paper were the announcement and description of the anatomy and physiology of the palate in its cleft condition, and also the application of this knowledge to the surgery of cleft palate.

I had taken up certain views of my own upon this subject, and had made inquiry for the purpose of ascertaining if these same views had been entertained or promulgated by any other surgeon or physiologist prior to myself; but I could not ascertain that any one else had ever described the physiology or the movements of the parts in the cleft palate; in fact, that investigations which had been already made only tended to convince surgeons that they were left in almost utter ignorance of the movements of the parts and of the causes of the movements in this condition.

Now, when you have a person before you whose palate is cleft in two, and you look into his mouth and ask him to imitate the act of swallowing, the edges of the cleft, and more especially of the posterior portion of it, approach each other, and the fissure is much narrowed; and if a spasmodic action of the palate is induced by irritating it, the two portions of the uvula fall together. This movement of course had been noticed by those surgeons who had paid particular attention to the subject; but although it had been observed by them, they had not been able to understand it. Malgaigne, indeed, had referred to this very movement as the one he was perfectly unable to explain. In the investigations I carried on, I fancied I explained this movement satisfactorily; and any one who could see the preparation which I made, and from which I instituted my observations, and would reflect carefully upon the matter, will understand that this hitherto unexplained and difficult point can now be easily and clearly understood. Now, no one had ever thought about the possibility of the sides of the cleft palate being pushed together; but such is the case, for the superior constrictor of the pharynx, from its peculiar situation, and from the disposition of its muscular fibres, has this pushing effect upon the palate, and it is this which causes the sides of the cleft to approach each other. As I have before stated to you, this fact was one of the main features of originality in my paper. All surgeons prior to that time had seen that one great obstacle to the uniting of the wound was the constant dragging of the soft parts. The lateral portion of the palate was so moveable, that there was a constant tension on the stitches; in fact, to a greater degree than exists after the hare-lip has been united. Surgeons knew that this was the great obstacle to the uniting of the wound; but the precise cause of it was uncertain, and remained so until I made my observations. I then announced that the principal muscle which dragged the parts outwards was the levator palati. I also showed that the palato-pharyngeus acted in such a manner as to exert an unfavourable influence on the soft palate. There can be no doubt that this muscle, which, you know, constitutes the posterior pillar of the fauces, acts differently in the cleft state of the palate and in the natural state of parts. In the natural condition it has the tendency to close the posterior part of the fauces, as it draws the parts towards the centre; but when the palate is cleft it acts otherwise; this muscle, indeed, helps to drag the flaps of the palate outwards. Well, from all the inquiries which were made, I came to the conclusion in my own mind, that if the levator palati and palato-pharyngeus muscles were divided preliminary to bringing the edges of the cleft in contact, the parts would be much more likely to lie in apposition, the tension would be taken off the edges of the wound, and the unsuccessful results which had hitherto obtained would in this manner be prevented. In my observations, some other and minor points were referred to, such as the action of the palato-glossus and tensor palati, which were shown by me to have but little action. It would, indeed, appear on first consideration, that this latter muscle would have a powerful effect upon the soft palate; but if you examine this muscle carefully in the cleft condition of the palate, or in the natural state of parts, you will ascertain that in reality this so-called tensor has scarcely any action at all upon the soft parts, while, on the contrary, you will observe, that the levator palati is the muscle which principally acts in pulling the flaps of the cleft upwards and outwards.

I must here mention, that some of the incisions which were recommended by some surgeons had nearly accomplished the object which I have in view; for instance, the incision of Dieffenbach, which was made through the whole thickness of the palate on each side of the cleft, most likely

involved the levator palati muscle; that Dr. Mason Warren probably included a portion of the palato-pharyngeus; but still there never had been made the slightest allusion to the anatomy of the parts by these surgeons, and, in their operations, there could be no scientific or anatomical precision. But, in the proceeding which you have seen me adopt, I know what particular textures I divide, and I know for what reasons I divide them, and the results of my operations have been most satisfactory; and hence I cannot help thinking that the method is the most correct one, and I must strongly advise you to follow it.

There is one point of very great importacce, in connexion with the after-treatment of these cases, upon which I also forcibly dwelt. It was formerly the custom not to allow the patient to take any food for some two or three days after the operation, for fear of the muscular action which is necessary to swallowing disturbing the union of the parts; in fact, the patient was literally starved,—so that the remedy became worse than the disease. However, I determined to allow my patients food as soon after the operation as they chose to have it; of course, it was given to them only in a fluid form. I found the great advantage of this plan, and strongly inculcated its observance. I must, however, do Sir Philip Crampton the justice to state, that he had resorted to the same measure occasionally before. In, however, recommending that the patient should take food immediately after the operation, I must beg you to understand, that I do not allow my patients any solid nourishment, but only food in the shape of fluids, such as broth, beef-tea, and arrow-root.

Now, we have had two very interesting cases of cleft palate in the house lately, and you have seen me adopt the particular mode of operation above referred to in both instances, and in each of them the result has been everything we could have wished. In the first case I operated on,—both of them were young men,—the fissure only went through the soft parts, so that it was a most favourable case for an attempt to close the opening; but the second case was somewhat complicated, as the cleft implicated the hard as well as the soft palate. Here, moreover, there was a bridge of communication of soft tissue in the centre, so that the fissure was divided into two almost equal portions. This condition was probably an advantage; so I determined to operate only upon the hinder portion first, and this I did in my usual manner; and you have all seen how very favourably union has taken place. The patient is now to go into the country, and is to return at the termination of a few months, when it is my intention to perform an operation upon that portion of the cleft which still remains open. In the case first mentioned, where the cleft was much less extensive, I performed the same kind of operation, having divided the levator palati muscle on each side, prior to bringing the edges into contact; and the result was a perfect cure.

Now, you must all notice what a difference there is as to the sensitiveness of individual patients, and the power of bearing the operative process. In one case we have an immense deal of trouble, in consequence of the excessive irritability of the parts, and the want of firmness on the side of the patient. In another instance we shall find just the contrary, and here the operation is rendered comparatively easy, although it is a difficult one under any circumstances. Now, in the second case you saw this exemplified; the young man was firm and determined to bear the necessary process with patience, and the parts were by no means so irritable as they are usually found to be; consequently, there was little difficulty or delay here, and indeed everything has turned out as well as we could possibly wish.

Now, gentlemen, before concluding this subject of cleft palate, I will contrast these two very fortunate cases with a case which is now in the house. I am speaking of the young woman, upon whom I operated last Saturday. Here was a deformity in the velum, but it was not the usual congenital deficiency I have been speaking to you of. She had an aperture in the soft palate, which was so large as to admit the little finger into it, and it had been produced by disease. It is generally the custom to close these artificial openings by small plugs of different materials; and much ingenuity has been displayed in their construction and adaptation. In this instance, however, I thought I would endeavour to close the opening by an operation. You saw that I brought the edges of the opening well together, and accurately adapted them by sutures, and for the first forty-eight hours the wound looked well, and appeared as though it would heal; but unfortunately it has since broken open, and the patient is as bad as she was before. I must tell you, that in cases of this description, where there is an opening in the soft palate produced by disease, for the most part syphilitic, there is very little chance of doing good by an operation. I have tried on various occasions to close openings of this nature, but cannot flatter myself with being successful.

ORIGINAL COMMUNICATIONS.

EXCISION OF JOINTS.

By G. M. JONES, Esq.,
Surgeon to the Jersey Hospital.

[Continued from page 289.]

Case 2.—John de Ste. Croix, a short-set muscular man, aged 38 years, by trade a whitesmith, was admitted into the hospital on the 17th March, 1851, with disease of the left elbow-joint, ten days before which I had visited him at his house, and there learned the following account of his case:—

Upwards of three years ago he experienced pain of a lancinating kind in the elbow, and shortly afterwards perceived two small lumps, which occupied, according to his statement, one the radial, the other the humeral portion of the joint. This induced him to consult his "club doctor," who with a lancet abstracted from a vein a quantity of blood, as a means of removing this local affection. The pain not subsiding, he applied to various other medical men, whose prescriptions he followed, and occasionally with apparent benefit, nor did he refuse to listen to and adopt the advice of quacks. He was not aware of having received any injury or hurt; but, from the time he first suffered in the elbow, he had never for many days together been exempt from pain, which frequently prevented his working; and at one period he had to lay up for six weeks. The pain was almost always more acute during the night, and would often wake him. It was, however, only one week before I was called in that serious symptoms manifested themselves, the whole arm, but more particularly the joint and its surrounding parts, becoming almost suddenly inflamed, and the pain attending it excessively severe. His sufferings at this time were most distressing; the whole arm, from the shoulder to the fingers, was in a state of phlegmonous erysipelas, and measured nearly twice the size of the corresponding limb. There was a small opening, not much larger than a pin's head, about one inch below the head of the radius, and another full two inches above the external condyle of the humerus; fluctuation was most distinct, so that I at once enlarged one of the openings, in order to give the matter free exit; a quantity of ill-conditioned pus escaped, and comparative relief followed. From this time till his admission into the hospital, irritative fever ran very high; tongue coated; pulse 130; and perspirations so profuse, as to render necessary a change of linen every four or five hours. The plan of treatment followed was that generally adopted in cases of this nature.

The erysipelatous affection having considerably lessened when he was admitted into the hospital, a more careful examination took place than had up to this time been deemed prudent. Any attempt to move the joint gave excruciating pain, the effort, however slight, occasioning, to use the patient's own expression, "the bones to rub one against the other." A probe introduced into either of the openings above alluded to at once proved that carious bone existed, and burrowing sinuses could be detected running in all

directions not only near the diseased articulation, but in parts some inches removed from it. The integuments of the whole arm were, however, in such a state, that local treatment seemed absolutely required before any operation could with much prospect of success be resorted to; but a train of symptoms, dangerous from the extreme debility they were occasioning, prompted me (with the concurrence of my friends) to remove without further delay the cause, which was not only rapidly undermining an otherwise healthy constitution, but threatening life itself.

In this case of excision (the operation was performed on the 30th of March) I followed, as nearly as circumstances allowed, the plan laid down and adopted by Syme. The dreadfully diseased state in which I found the bones of the joint, as well as the surrounding soft parts, excited a doubt whether, after all, amputation, if not the more justifiable, would, at all events, prove the safer course to pursue; but, knowing from experience that Nature can effect very much more than she is generally given credit for, I determined to test her powers in this instance. The integuments throughout were in a much greater state of disease than I had in the least anticipated; it was like cutting through a soft gelatinous and pulpy substance. The under portion of each flap, and other of the surrounding parts of the entire joint, were in some places so diseased as to make it necessary here and there to remove pieces with the knife. Both ulna and radius at their connexion with the humerus were carious, and the latter bone, to the extent of 1¼ inch, very much so. There was not only complete destruction of the articulating surfaces, but some portion of the substance of the bones participated in it also. The operation, which was rather a tedious one, was completed with but very little hæmorrhage, the flaps were brought together by means of sutures, (the state of the integuments permitting but little reliance to be placed on them,) and the arm laid in a semi-bent position.

About an hour after the operation, ʒij. of tinct. opii were given, and beef-tea ordered to be frequently taken.

9 p.m.—Has experienced nausea several times; feels restless; pulse 135; thirst; tongue moist; has had no sleep; considerable pain in the arm.

Saline draughts, with ♏x. of tinct. opii, to be taken every three hours.

31st mane.—Has had some sleep during the night. Pulse quick, but more quiet than yesterday; a cold, clammy sweat over the body.

A glass of port wine every three hours, preceded by ʒj. of quinine mixture. Beef-tea and other nutritious diet to be occasionally taken.

Vespere.—Much the same as this morning.

April 1st, mane.—Slept at intervals during the night, perspirations very severe for three or four hours; pulse very weak, and 135; tongue rather coated and inclined to be brown; feels but little pain in the arm.

Two and a half grains of quinine every three hours, and a pint and a half of port wine to be taken during the twenty-four hours.

Vespere.—Pulse 120, and stronger; enjoyed a dinner, consisting of roast chicken; tongue moist.

2nd mane.—External dressing removed; wounds have discharged a great deal; general appearance unhealthy; pulse 114; slept full five hours during the night; tongue much cleaner; appetite good; perspired very much towards morning.

Continue the same. A bottle of porter in addition to wine.

Vespere.—Has passed a tolerable day.

3rd mane.—Bowels acted on for the first time since the operation; slept several hours during the night; pulse 96, and soft; copious discharge from the wounds, unhealthy in appearance; adhesive straps removed, the integuments for some extent dark coloured, and when pressed on have a pulpy feel, at the same time a considerable quantity of fetid pus, much tinged with blood, bubbled out; sutures came away with the dressings.

Two adhesive straps applied for the purpose of support, and water-dressing. Diet of the most nutritious kind to be taken, in addition to the port wine and quinine.

Vespere.—Has eaten very well during the day; feels much more comfortable than he had yet done; pulse tranquil; tongue clean.

4th.—Discharge from the wounds still very copious, and unaltered in character; the lower arm much swollen, and in some parts, particularly on the radial side, hard: experiences but little pain, has slept well, and relished a meat breakfast exceedingly; pulse 90, and much improved in strength.

The water dressing to be applied over the whole of the forearm, as well as on the diseased parts; bowels acted on twice; evacuations natural.

5th.—Has, for the first time, found the perspirations less; slept almost the whole night; discharge from the wounds less copious, and more healthy; granulations here and there florid; the forearm less swollen.

Continue the same.

6th.—The same as yesterday.

13th.—From the 6th to the 13th, his appearance and general health have daily improved; he has slept well; bowels regular; appetite very good; perspirations trifling; pulse 90, sometimes 94. The discharge from the arm still continues very considerable; some portion of the inner longitudinal incision has healed by first intention; it is, however, evident that every other part will heal by granulation, and equally so that, in consequence of the diseased state of the integument, a considerable time must elapse before the sinuses can close, and healthy integument supply the place of that which was and still is so disorganized.

Water-dressing to be continued. The arm was this morning placed in an appropriate splint, and the patient was allowed to sit up.

20th.—The arm, since the last report, has gradually improved; it is rather painful and tender in two or three parts, but more particularly in one spot, about three inches below the removed portion of the ulna; pulse almost natural, both as regards frequency and strength; there is considerable œdema, extending from the wrist to the bend of the arm; very little above. He can move his fingers with more facility than he had yet done.

The same local treatment to be continued, and the many-tailed bandage to be applied rather tighter; the diet to be still of the most nutritious nature, and wine, quinine, and porter to be taken as before.

30th.—Wounds are filling up, though slowly; the œdema has considerably subsided; feels much stronger.

The same treatment to be continued.

May 10th.—There is still considerable discharge; the sinuses are evidently closing, and the general aspect of the parts more healthy. The forearm is its natural size; the arm smaller.

The water dressing to be continued: port wine to be reduced one-third; quinine also; porter or ale to be taken as before.

29th.—From the 17th April to this date he had been up daily; had frequently left the hospital for hours together, and occasionally for the whole day. The night before last he remained out later than usual, in consequence of the weather, and returned to the hospital with his clothes wet. During the night he felt chilly and unwell, and is now very feverish; skin dry; tongue coated; pulse hard, and 96; coughed several times during the night, and the sputum, which was at first tenacious, is now uniformly of a rusty colour; breathing difficult, and any attempt at taking a long inspiration causes instant cough, and very great pain in the right side.

Thirty ounces of blood were at once abstracted from the arm, a blister applied to the side, and an aperient powder given. Linseed-tea to be taken *ad libitum*.

Vespere.—Breathing still continues difficult, coughs much, sputum streaked with blood frequently. The blood abstracted in the morning is highly inflammatory. Pulse softer, 104. Bowels have been freely acted on five times; thirst very considerable, has drunk very largely during the day; blister has risen.

℞ Ant. tart. gr. viij., tinct. opii ʒij., nit. pot. ʒij., mist. camph. ʒviij. M. Cap. cochl. mag. ij. sum. quaq. quartâ horâ.

30th.—Cough much less than yesterday, expectorated freely, sputum much less tinged. Has had some sleep; skin moist; pulse 90, and soft; still experiences much thirst; tongue coated, but not dry; the appearance of the arm much the same as at last report.

By following up the antiphlogistic treatment for several days, and having recourse to derivants and expectorants, milk diet, etc. etc., the pneumonic symptoms gradually sub-

sided, so that on the 28th June he was, at his own request, discharged as an in-door patient; cough, expectoration, and all pain, both in the side and chest, had left him. The healing of the arm, though progressing favourably, has evidently received a check; still there is nothing to indicate an unsatisfactory termination.

Ordered to attend at the hospital every second day.

Sept. 25.—The arm may now be looked upon as cured; for some time past the discharge has been so trifling as scarcely to soil the lint; at present there is none whatever; several of the wounds have so cicatrised as scarcely to leave the least scar. The arm can be easily straightened, and there exists but little doubt that in a few months he will be able to bend and straighten it at pleasure.

Last Report.—This patient has for some time past followed his usual employment, and is able to earn very tolerable wages: he finds his arm become daily stronger, and can now use it to dig, carry pails of water, etc.

I have omitted mentioning that Ste. Croix was at one time a great pugilist, which renders it probable that either a blow or a fall occasioned the disease which led to the resection of the elbow-joint.

Case 3.—On the 4th June, 1849, John Le Gros, a boy nearly nine years old, was admitted into the hospital in consequence of an affection of the left knee, the result of a kick he had received three weeks before from one of his school companions: this was not attended to at the time, nor had any remedy been employed. When I saw him the affected joint was much swollen, and was attended with symptomatic fever of the inflammatory kind; perfect rest was enjoined, and the antiphlogistic treatment followed out both in a surgical and dietetic point of view. At the expiration of a month the knee regained its normal size, and, although the danger attending an early removal from the hospital was pointed out to the patient's mother, she persisted in his being discharged, and her wishes were accordingly complied with. Five months after he again became an inmate, and for the same affection; local and constitutional remedies were once more resorted to, and apparently with advantage, for in six weeks there was evidently an amelioration of symptoms. Without my consent or knowledge the boy was removed, and from that period to the 6th April, 1851, I entirely lost sight of him. On that day I was requested to visit him, and learned that he had been able to walk tolerably well for a month or two after leaving the hospital, but was at length obliged to have recourse to crutches. Iodine ointment was the sole application which had been used, and that only for a short time. The poor boy was to all appearance sinking from irritative fever; pulse small, and upwards of 130; emaciation very great; features attenuated, and the whole body had a cold, clammy feeling; his nights were either sleepless or extremely restless. The affected knee was very much swollen, and had an elastic feel; any attempt to move the joint gave excruciating pain, and this, together with the extreme tenderness of the part, left little doubt that extensive disease of the joint existed. The skin was considerably raised from the patella to rather more than half up the thigh; the swelling had a conical form, and, as fluctuation was very perceptible, the fluid, of which there was a large quantity, was at once evacuated by means of an opening made in its most projecting point. This gave temporary relief, but as the hectic symptoms daily increased, and also the diarrhœa, (which was of some standing) and the mother had no means whatever of supporting her child, he was, on the 14th of the same month, admitted for the third time into the hospital. From this day to the 27th every attempt was tried to strengthen the system, and this was in some degree accomplished by means of nutritious diet and tonics combined with astringents. The discharge from the thigh, however, increased rather than diminished, as also the emaciation of the whole body, so that it was evident there remained no chance of saving life except by amputation or excision of the joint. In the wretched state of the patient neither offered much hope of success, but the unwillingness of both mother and child to have the leg removed decided that the latter plan should be attempted.

On the 27th of April, in presence of several of my medical friends, I excised the joint, following almost throughout the operation the same plan that had been adopted in Sarah Hansford's case. As in hers there was but little hæmorrhage; no vessel required a ligature; there was a considerable quantity of matter within the joint, and not only the articulating surfaces were destroyed, but much also of the substance of the bone was found to participate in the disease; the ligaments, also, were partially disorganised, and the under part of the patella partook in the general affection. The portion of bone removed from the femur and tibia measured 2¼ inches. The operation lasted seven minutes; the edges of the wounds were brought together by means of sutures, and the limb was secured in a box with pads, etc. etc. A state of great exhaustion followed the operation. Two hours after thirty-five drops of tinct. opii were given, and strong beef-tea and port wine ordered to be taken frequently.

Vespere.—Apparently but little oozing from the wounds; pulse exceedingly quick, too much so to be accurately counted; complains of excessive pain, has had no sleep, and feels restless and exhausted; the whole body covered with a cold clammy sweat; the kidneys have acted freely.

℞ Tinct. opii gr. xl., tinct. card. co. ʒiij., mist. camph. ʒiss. M. ft. Half to be taken immediately, the other half in two hours, should the pain continue.

Port wine to be taken frequently.

28th mane.—Took both portions of the draught, but had very little rest; suffers much less than last evening; temperature of the limb not greater than might be expected. Pulse 140, small; tongue coated, but moist; perspirations as great as ever; no appetite.

Two grains of quinine, and one glass of port wine, to be taken alternately every three hours, and strong beef-tea to be given frequently.

Vespere.—Pulse rather stronger than in the morning, and 135; tongue less coated; perspired most profusely from four till six. Has taken the quinine and wine regularly, but very little beef-tea.

29th mane.—Has passed a sleepless night; pulse as last evening; had a natural evacuation during the night; tongue much cleaner, and perfectly moist; cheeks hectic; perspirations in no degree lessened. The leg seems to lie comfortably, and is by no means painful.

Ordered cocoa for breakfast, and a chop for dinner. Medicine and wine as usual.

Vespere.—Ate but little for dinner, and is in every respect much the same as in the morning.

30th mane.—The bandages and dressings were removed this morning. The aspect of the wounds showed that but little, if any, would unite by the first intention. Some of the sutures were removed. The discharge was copious, moderately thick, and, although in character not everything that could be desired, was not worse than was to be expected. That from the opening in the thigh was abundant. The water-dressing to be applied, together with moderate pressure over the whole limb, from the ankle upwards. Considerable exhaustion followed this dressing, which the extreme nervousness and timidity of the boy were in themselves sufficient in a great measure to account for.

Vespere.—Has passed a more quiet day than he had done since the operation. Pulse 132, small, but regular; perspirations as great as usual; enjoyed some roast duck for dinner and is tolerably cheerful.

Wine, quinine, etc., to be continued.

May 1st, 9 a.m.—Has had six copious watery evacuations since six o'clock; is looking wretchedly ill. Pulse 140, very thready and flickering; tongue dry, but not coated.

To take frequently arrowroot, with brandy in it, and a table-spoonful of an astringent mixture every two hours; and when thirsty, port wine and water, or rice water with cinnamon and brandy in it.

Vespere.—Bowels have only been acted on twice since the morning; evacuations less copious, and more consistent; pulse equally frequent, but not so weak; features not so attenuated. The leg was dressed at mid-day, and appeared much the same as yesterday.

Mixture to be taken every five hours.

Arrowroot, etc., the same.

2nd mane.—Has slept but little, and that little was much disturbed. Pulse very weak. Two evacuations during the night, not copious. Complains of great pain all down the leg. Integuments about the wound very puffy, particularly on the outer part. Several of the sutures came away with the dressing. General appearance of the parts unhealthy. Considerable discharge of ill-conditioned pus from the sinus in the thigh.

A glass of port wine every three hours.

℞ Mist. cretæ comp. ʒi., quinæ sulph. gr. ij., tinct. card. co. ʒss., ft. haust. quâq. quartâ horâ.

Vespere.—Bowels have not been acted on during the day; pulse 132, stronger than in the morning; perspirations very considerable. Relished two cups full of beef-tea, and broiled meat.

Continue the same.

7th.—From the 2nd to this day there has been but little improvement, with the exception of the bowel complaint, which has not returned. Appetite very bad; tongue clean; pulse 130; perspirations very profuse; discharge from the wounds rather more healthy than at last report, but very abundant. This morning there is less pain in the leg, and he seems more cheerful than he has yet been. Has not the least appetite for meat or broth.

The same quantity of quinine to be taken, but in powder. Chalk mixture to be omitted.

As much milk as he fancies.

14th.—The wounds this day assumed a more gratifying appearance than they had yet done. Pulse for the first time under 130; tongue clean; countenance much less expressive of pain and anxiety. The discharge also from the wounds, and from the sinus in the thigh, less copious, and of a more healthy character. Sleeps better, but very far from well. Perspirations have not lessened; more emaciated than ever.

Continue the same, and pale ale to be taken three or four times during the twenty-four hours.

18th.—Complained of occasional rigors during the night, and was unable to sleep in consequence of pain along the outside of the leg. Pulse rapid; a shining blush of some extent on the part complained of; wounds have discharged much as usual; edges have a moderately healthy appearance. Appetite improved.

A linseed poultice to be applied to the painful part.

19th.—Night has been sleepless, in consequence of a throbbing pain extending almost all down the leg. Pulse 128; cheeks hectic; has perspired more than usual.

Full a tablespoonful of laudable pus was evacuated by means of a lancet from an abscess which had formed about an inch below the external transverse incision. This gave instant relief. The wounds are filling up, though slowly, with healthy granulations; sinus in the thigh still continues discharging; three or four very small sequestra of bone which were visible were withdrawn by means of the forceps.

Hot-water dressing to be applied. Citrate of iron cum quinine to be taken every four hours, and as much nutritious food as the stomach can bear.

30th.—Another abscess, situated about two-thirds up the inner part of the leg, was this morning opened. The matter which flowed from it was thick and healthy. All the other wounds are going on favourably.

Treatment to be continued in every respect the same.

June 10.—Health has gradually improved since last report. A copious discharge still continues from the different wounds, and more particularly from the one caused by the abscess, which was opened on the 19th. Perspirations equally great when they occur, but not so general nor so frequent. Appetite much better. Has taken for some days past upwards of three quarts of milk during the twenty-four hours. There is not, nor has there been, the slightest œdema of the foot or leg. Pulse 100; still very weak, but regular. Bowels opened once a day. Wounds cicatrising.

Diet as well as medicine to be continued.

The body and limbs to be sponged night and morning with the pyroligneous acid lotion.

25th.—Every day for the last fortnight has been taken down, and remained for several hours each day in the open air; countenance has lost all expression of anxiety; and, though the emaciation is still very great, it is evident that for some time he has gained flesh. Pulse 90, and moderately strong; appetite quite as good as at any time during the last two years. Two other abscesses have discharged, both situated in the popliteal space; neither are deep, and they seem to have arisen more from some undue pressure than from any other cause; discharge from wounds and sinus in the thigh much less.

Water dressing to be continued.

Wine, pale ale, and medicine as usual.

July 10th.—Very considerable improvement has taken place since the last report; there is no œdema whatever, and the sinuses are healing. There is another opening, self-made, at the under-part of the leg; very healthy pus issues from it, as well as from other parts not yet healed; appetite is very good, and he relishes his meals; pulse 80 and firm; tongue clean; perspirations have altogether left him, and his nights are very good.

Same treatment to be continued.

August 1st.—Union of the femur and tibia has decidedly taken place; the head of the former bone is distinctly felt moving under the finger when rotated from the foot, and the whole limb is raised easily by the patient with but very little help. The sinus in the thigh still discharges; health is evidently improving daily. The leg is inclined to bow outwards, and is somewhat bent.

Treatment the same; and the box to be so padded as to keep the leg as straight as possible.

25th.—Is now quite convalescent. The discharge from the different wounds is very trifling; some have healed.

Last Report.—Is now able to walk a considerable distance with the assistance of a stick; and it is probable that in a short time he will not require even this support. The limb still bows outward, but not so much as it did. The bend before mentioned, I conceive, facilitates his walking. He can with ease support his whole body, which is now in excellent condition, on this leg. Three or four superficial ulcers still keep up a slight discharge; but there cannot be a doubt that, as the improvement of the constitution advances, these nearly healed ulcers will disappear.

[To be continued.]

PRACTICAL OBSERVATIONS ON DISEASES OF THE EAR.

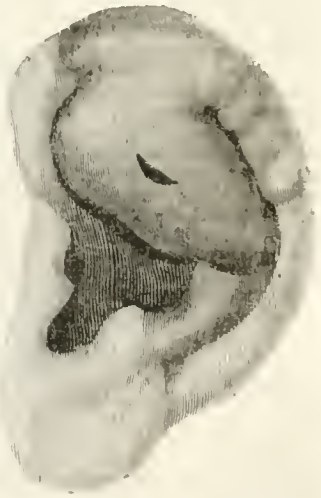
WITH RECORDS OF CASES TREATED AT ST. MARK'S HOSPITAL, DUBLIN.

By W. R. WILDE, Esq., F.R.C.S., Etc.

(Continued from page 315.)

No. 18.—TUMOUR OF THE AURICLE.

J. E., 24, male; a printer. A tumour, about the size of a small pear, occupies the upper portion of the left auricle, between the helix and the concha. It is immovable, and has a tense, elastic feel, like that of a hydrocele, and the skin covering it is smooth, and of a dusky red colour. It is of three months' duration, and has been several times lanced by a medical man, and a quantity of glary matter discharged. As soon as the wound healed, the fluid re-accumulated. Hearing unimpaired. The whole auricle is very hot, but the pain is not great. The case, when admitted, presented the character shown in the accompanying illustration.

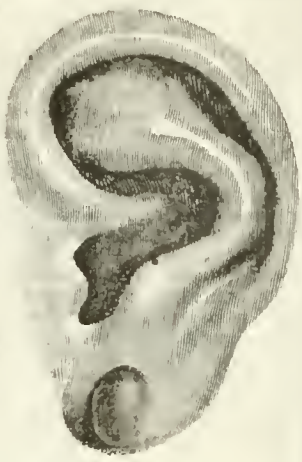


A free incision was made through the entire length of the tumour, and about two ounces of glairy tenacious fluid, of a yellow colour, like that contained in a ranula or an enlarged bursa, but mixed with portions of flocculent matter, was discharged. The sac was found to be smooth and polished. The wound was dressed from the bottom, with dossils of lint and a cold lotion applied to the auricle. Under this plan of treatment, the fluid did not again accumulate, but the auricle presented a hard, thickened, nodulated feel and appearance, which remained for months, and completely effaced the natural curvatures and sinuosities of that portion of the external ear. The patient, while he remained in attendance at the Institution, took Plummer's pill and bark, and had the thickened auricle painted over with tincture of iodine every third day. This is a rare form of disease in man, but I have frequently seen it in dogs, where it forms a hard lump attached to the end of the long flexible auricle. In one instance that I remember, it caused so much inconvenience to a valuable pointer dog, that it had to be excised.

No. 19.—FIBROUS TUMOUR OF THE LOBE.

M. S., 19, female, has a hard, firm, ovoid tumour, occu-

pying the centre of the lobe on each side, but largest on the left, of which the accompanying woodcut affords a faithful representation. It is of a stony hardness, and is quite distinct from the cartilage above, and the fleshy part of the lobe, which it appears to pass through. The skin covering it is smooth, and of a light pinkish hue, like that of a keloid tumour. It grew gradually from the orifice made for holding the ear-ring, and has been several months attaining its present size. The tumour upon the opposite side, which also surrounds the hole made for the ear-ring, is much paler in colour and not larger than a garden pea. The girl states, that she experienced a great deal of pain and soreness in the wound made in piercing her ears, and that about three or four months afterwards she was obliged to remove the ear-rings on account of the irritation they produced. The large tumour was dissected out, and the eliptical aperture left in the lobe brought together with sutures. It healed kindly, and the disease did not return. A section of the tumour exhibited a dense yellowish white fibrous appearance, and was so hard, that the nail made little impression upon it. I saw this patient about three months ago, and as the excrescence in the lobe on the right side had not increased, she was unwilling to have it interfered with.



If tumours of this description were frequently to follow the irritation caused by piercing the ears we should find them much more common, particularly among those nations who wear very large, heavy, pendulous ornaments there; but I have frequently seen the hole made to hold the earring elongated to a slit three quarters of an inch long in some of the African and Oriental tribes. The South Sea Islanders, as you are aware, introduce pieces of wood, shells, and other large substances into apertures made in the lobes.

In a case of goitre, where the tumour extended over the side of the neck along the course of the mastoid muscle, which I remember seeing in the west of Ireland some years ago, the lower portion of the auricle was enlarged to the size of the palm of the hand; and we read that pendulous tumours, growing from the external ear, are not unfrequent in those parts of India where goitre prevails. Mr. Williams, in his Treatise on the Ear, relates a case of tumour of the lobe which was removed by Professor Syme, and which, from the description, would appear to be very similar to that which I have described. Dr. Graves has published a case of fatty deposit in the lobes in a gentleman who died of fatty degeneration of the liver. The same eminent authority has also related a case of gouty congestion of the ear, apparently caused by metastasis. Swellings of the auricle are said to be common among lunatics, but I have no experience thereof. Boyer, in his Treatise on Surgical Diseases, has related a case of a large pendulous lobe, which he removed.

No. 20.—CLOSURE OF THE MEATUS AUDITORIUS EXTERNUS.

T. S., female, aged 54, has become deaf gradually during the last three or four years—tinnitus aurium. No pain or soreness in the ear. There is but little to be learned from the history of this case. A glance at the external ear affords us a tolerably good idea of the cause. Upon looking at the external meatus we perceive that it has lost its usual ovoid shape, and has become a mere elongated slit, or fissure marked by a dark line where the incurvated edges are in contact. Upon drawing forward the tragus, you perceive that I rather increase the defect, but upon grasping the auricle between my finger and thumb, immediately above the little protuberance called the anti-tragus, and drawing it outwards and a little forward, you see that I can to a certain extent restore to its natural size and position the external auditory aperture. The hollow formed between the tragus and the external meatus is much larger and shallower than natural; and on pressing with the finger in front of the tragus and beneath the zygoma, where the skin is rather corrugated, we are unable to push the tragus backwards into the concha so as to cover the meatus externus, to which in normal cases it ought to act as a sort of lid or operculum. Upon examination with the speculum, we find the flexible walls of the auditory tube compressed, the lining of the passage white, and its cuticular investiture thickened as if by maceration and detached in patches, while a slight, whitish, curdy discharge collects round the edge of the tubular speculum. The tympanal membrane is white, and apparently thickened. There is no evidence of ceruminous secretion in any portion of the passage.

Upon enlarging the external meatus, either by the means which I first pointed out to you, or by the introduction of the speculum, you observe that the hearing is increased. She can now perceive the ticking of the watch at six inches. Previously she only heard it when pressed against the auricle.

Closure of the external meatus may arise from a variety of causes, of which you have examples in the series of drawings now exhibited. In the instance before us, it does not seem to be the result of any inflammatory process, but appears to have been caused by some force gradually exerted upon the tragus, and drawing its point forward toward the cheek, and pressing its base backwards—possibly permanent spasm of the tragicus muscle. It is a very slow and gradual process, and is, therefore, seldom attended to by the patient, until complete closure of the meatus ensues. The deficiency of cerumen, the thickened cuticle, and the slight discharge which you observed in the passage, are the result, not of the original disease, but the subsequent closure and pressure of the sides against each other. It is a disease of middle or advanced age. Although it attacks one ear first, it is generally found in that on the opposite side. It is most difficult to manage. I have had thoughts of making an incision in front of the tragus, so as completely to divide any muscular fibres which might have produced the deformity; but I fear that plan would not be attended with much success, for I have, from long experience, remarked, that when once any of the free cartilages, as of the eye-lids, nose, or auricle, become viciously bent or distorted from their natural position or curvature, that it is almost impossible to restore them by any effort of art. I have used tents made of compressed sponge for the purpose of gradual dilatation; but I cannot say that I have effected much thereby. They should, however, be given a fair trial in every case. The tube ought to be cleansed from those impurities which you observe have collected therein, and the parts washed over with a strong solution of nitrate of silver, and a fresh tent should be introduced every night, and removed in the morning. With intelligent persons, in the upper ranks of life, this plan of treatment, if proceeded with for a sufficiently long time, may be attended with benefit; but, with careless, stupid people, among the lower orders, who pay little attention to cleanliness, we have but a slight chance of success. The defect of hearing arising from this (in the first instance) mechanical cause is one of the few cases that may be relieved by the introduction of a small metallic tube shaped like a wine-funnel. You see those constantly advertised as a means of relieving every description of deafness. I need not tell you, from the rarity of the peculiar disease to which they are applicable, in how very few cases they can afford relief; but, as they are silver-gilt, are sold in very neat morocco cases, and cost a guinea and a half, they serve the purposes for which they are advertised by their proprietors. Several years ago I had under my care a case of this description, in a very intelligent old gentleman, and having made an accurate wax cast of the concha and meatus, while the latter was drawn open, as I have just described to you, my friend, Mr. Grimshaw, made the silver plate which I now show you, and which fitting accurately to the parts gave no inconvenience, was not remarkable, and very much improved the hearing. Pads have been constructed to fit behind the ear, and press the auricle forwards; but they do not afford the desired relief. Persons who are aware of the cause of their deafness do not, when speaking to you, place the half-closed hand behind the auricle, in order to collect sound, but very soon learn how to enlarge the meatus, by drawing the auricle outwards and a little backwards.

In ordinary cases of otorrhœa, particularly where the discharge is profuse, the meatus is often rather larger than natural, and the excoriations which sometimes occur where the matter is of an ichorous character, being always more or

less moist, and not forming crusts and scabs, do not produce any contraction of the external aperture; but other cases occur where the meatus is closed by morbid growths, of which the following instance is an example.

[To be continued.]

CASES AND OBSERVATIONS

ILLUSTRATING THE THERAPEUTIC EFFICACY OF

DILUTED HYDROCYANIC ACID

AS A TOPICAL APPLICATION IN CERTAIN

AFFECTIONS OF THE EYE.

By JAMES VOSE SOLOMON, Esq., M.R.C.S.,

Surgeon of the Birmingham Eye Infirmary, late Surgeon to the Birmingham General Dispensary.

[Continued from page 369.]

STRUMOUS OPHTHALMIA OF SEVENTEEN WEEKS' DURATION CURED IN LESS THAN THREE WEEKS.

TREATED BY DILUTE HYDROCYANIC ACID AND IRON.

Case 6.—Upon the 25th of February, 1842, I was requested to visit E. L., a little girl 7 years of age, the daughter of persons in a respectable station of life, some of whose children had died of scrofulous complaints. On arriving at the house, I found my patient sitting in the corner of a small and dimly-lighted back room, with her face turned towards the wall, playing with some toys. I was informed, that this had been her habit for the last sixteen or eighteen weeks; a stronger light was insupportable.

The child is pretty, of lively disposition, has regular features, and a pink and white complexion. There is no enlargement of the glands of the neck; the hair of the head is dark brown, cut short, and interspersed with hypertrophied follicles filled with caseous matter. The follicles inflame, ulcerate at their apices, and shrivel up. The eyelashes are well grown and silky-looking. The appetite is good; bowels generally relaxed. The conjunctivæ of the inferior palpebræ are streaked by a few straight vessels; the right cornea presents a pearl-coloured opacity; that of the left appears to be normal.

History.—In the course of the last five years, she has suffered from five attacks similar to the present one, the duration of each one averaging from four to six months. She has been treated by distinguished ophthalmic practitioners in Dublin and Birmingham, in the opinion of her parents with little benefit.

Treatment.—The hair to be cut short. A large shade to be worn on the forehead. The eyes to be frequently fomented with warm poppy decoction. Two or three drops of dilute prussic acid to be applied to the eyes night and morning. A small dose of castor oil to be taken at bed-time. A light and nutritious diet.

Feb. 26.—Can open her eyes, and bear a moderate degree of light. The castor oil has operated freely; the alvine evacuations are bilious. The application of the drops is reported to occasion trivial pain, which disappears in the course of about twenty minutes, and is succeeded by a greater degree of ease and tolerance of light than was experienced before their introduction. The photophobia was relieved in an hour after the first application of the acid.

Feb. 28 (the 3rd day of treatment).—The improvement in the tolerance of light is still more marked; the child now looks cheerful and happy.

℞ Tinct. ferri sesq., tinct. conii aa. ʒss., aquæ carui ad ʒvi. M., s. cochlear. duo larga ter in dies.

℞ Hyd. c. cretâ gr. j., pulv. ipecac. co. sodæ bicarb. exsic. aa. gr. ij. Ft. pulvis omni nocte s.; mitte doses tres.

March 18 (the 3rd week of treatment).—During the last fortnight, my little patient has been residing in the suburbs, and has spent most of her time in the day, as directed by me, in the open air; she has left off her shade, and can bear as strong a light as other persons. All the functions appear to be well performed.

Remarks.—This patient's eyes have continued, ever since this period up to the present time, perfectly well, with the exception of the occasional appearance of a hordeolum.

She is now (Nov. 1851) of robust contour, in good health, and much stronger than any of the other children of the family.

The history of this case is deserving of attention. We learn from it, that the child's enjoyments of the external world had been, for the last five years, curtailed more than one-third, indeed, nearly one-half of her life, the duration of the several attacks of ophthalmia having varied from four to six months; that medical treatment had been of little avail from the first commencement of the child's affliction up to the period of the prussic acid treatment having been adopted, and in this seizure sixteen or eighteen weeks were said to have already transpired; so that, *primâ facie*, it might appear that the termination of the disease was referrible rather to the period at which my services chanced to be called into requisition than to the particular treatment employed.

I am fully sensible of the efforts which are continually being made by Nature to throw off disease; yet when, in this case, I call to mind, that the beneficial agency of the prussic acid was manifested within an hour after its first application, — that the patient has ever since (*i. e.*, for nine years) enjoyed immunity from her troublesome disease —and that the case is not a solitary example of the propriety and excellence of the treatment of strumous ophthalmia by the topical application of prussic acid,—I must, in fairness, assume that the acid exerted a decided and unequivocally salutary influence.

PHLYCTENULAR OPHTHALMIA. — GASTRO-INTESTINAL IRRITATION. — CURED IN THREE WEEKS. — DILUTE PRUSSIC ACID AS AN EYE-DROP.

Case 7.—M. A. S., a little girl, 7 years of age, residing in a court in Ellis-street, was brought to me on the 28th Feb., 1842, at the suggestion of the mother of E. L.

The children had been in the habit of accompanying one another to a public institution.

Her countenance is pale and puffy-looking; the skin of the body is peculiarly soft and delicate to the touch; the irides are grey; the eyelashes coarse, and stunted at their points. The hair of the head is light coloured. The right eye is spasmodically closed, the lids have consequently a turgid appearance; the palpebral conjunctivæ are red. The marks of four leech-bites are apparent upon the lower eyelid. The stimulus of light is too painful to admit of the state of the cornea being satisfactorily ascertained. The left eye is not diseased. The abdomen is tumid and hot, and its superficial veins more marked than natural. She is restless at night, but no worms have ever been seen; the bowels are habitually costive; the tongue is covered by a thin creamy fur. She frequently vomits green frothy bile; the appetite is fickle.

History.—The mother states that her child has been more or less afflicted with disease of the eyes since the commencement of teething; she could not remember how many attacks she had had, but that their average duration was about six months. For the last six weeks she has been in attendance at a public charity. Upon her first admission there was a profuse yellow discharge from the eye, which was soon subdued by a lotion prescribed for it. As, however, redness of the eyelids and intolerance of light continued, leeches, blisters, aperients, and caustic drops, were subsequently employed, but without relief.

Treatment.—The following treatment suggested itself as likely to do good. S. pulv. ipecac. gr. x., statim ex theæ tepidæ cyatho.

℞ Hyd. c. cretâ, gr. ii., pulv. rhei gr. iii., pulv. ipecac. comp. gr. iii. Fiat pulvis omni nocte sumendus; mitte doses tres.

The eye to be frequently fomented with a warm poppy decoction. Two or three drops of the Pharmacopœial dilute prussic acid to be applied to the affected organ every night and morning. To subsist upon light nutritious food, and take plenty of out-door exercise.

March 4.—The fourth day of treatment. The mother reports that the child is better; the appetite is improved, and her sleep has become sound. The application of the drops produces pain, upon the subsidence of which the photophobia is relieved. To continue the powders, taking one every alternate night, the eye to be bathed with a tepid saturnine wash.

11th.—The eleventh day of treatment. The child presented herself to-day, which is cloudy, with her eyes open. There are one or two small albugos, probably resulting from phlyctens which have ulcerated, upon the right cornea. The tumid appearance of the eyelids is gone, showing that the spasm of their orbicular muscle has subsided. The conjunctiva continues of a red colour. The mother says, that

now her child runs about in the open air, but that prior to the late treatment her habit was to lie during the whole day with the face buried in a pillow. The tongue is clean, the papillæ of its apex red and elevated, the bowels regular, appetite good, sleep natural. Three drachms of castor oil to be taken at bedtime, and the stools therefrom to be examined. Pergat.

21st.—The third week of treatment. My little patient is to-day looking comparatively healthy. The corneal specks are nearly absorbed. Photophobia subsided. All the functions are reported as being healthy. The alvine discharges contain shreds of mucus.

℞ Vini aloes ʒiss., tinct. ferri sesq. ʒss. M. ft. guttæ; cujus capiat guttæ xx. ter in dies ex aquæ ʒss.

Remarks.—This child entirely recovered without any further treatment. The symptoms of depraved digestion were much more remarkable in this case than in that of E. L., as evidenced by the vomiting, variableness of appetite, tendency to constipation, and heat of the abdominal surface. The nature of the ophthalmic affection prior to my seeing the case, appears from the narrative of the mother to have been in the first instance catarrhal ophthalmia, merging, in consequence of the disordered condition of the primæ viæ, into the purulent form, which, when subdued by treatment, left the eye red and irritable. For the correction of these, four leeches, blisters, caustic drops, and purging-powders had been employed. This treatment failed, while a much more simple and soothing class of remedies, directed to the correction of the gastro-intestinal irritation and morbid sensibility of the affected eye, worked almost a charm in the course of three weeks, thus abbreviating the disease nearly two-thirds of what had been, on former occasions, its average duration.

Inflammation of the eye, of whatever kind, occurring in a person of strumous diathesis, is very prone to terminate in, or be complicated with, phlyctenular disease.

This patient continued free from ophthalmic disease up to February of the present year (1852) when she became my patient at the Eye Infirmary for acute catarrhal conjunctivitis of both eyes. She is now under treatment. Although the girl is healthy-looking, the disease is modified by the strumous diathesis; it dodges about from one eye to the other, and is attended by photophobia.

STRUMOUS OPHTHALMIA OF FOUR MONTHS' DURATION CURED IN SIXTEEN DAYS.

Case 8.—M. A. V., two years and a half of age, residing in Fordrough-street, was brought to me on the 14th day of March, 1842, presenting the following appearances and symptoms. The eyelids of both eyes are spasmodically closed; the inferior sinus of each palpebral conjunctiva is traversed by dilated vessels of a purple colour; the eyes are too intolerant of light to permit of the state of the cornea being decisively ascertained. The eyelashes are long and taper; alæ nasi broad; the lips tumid; gums free from irritation.

An eruption, crusta lactea, covers the chin, and extends to the commissure of the lips; the skin on the surface of the body is soft and delicate to the touch. The bowels are so irritable as to constantly disturb the child by straining. Her mother says that she sleeps with her face buried in a pillow, and that she rises at seven in the morning, but does not open her eyes until nine or ten o'clock in the day. The present ophthalmic affection is referred to an attack of scarlet fever, from which the child suffered four or five months ago. She has been under treatment for the last five or six weeks, at a public institution, and, in the opinion of the mother, has been but little benefited. I recommended very similar treatment, with the exception of the emetic, to that which was ordered in the last case.

At the expiration of sixteen days from its commencement, the facial eruption and ophthalmia were cured, and the muscular system had gained some tone. The child had been taken into the country for an hour or two every day, at all other times she had breathed the impure atmosphere of her home.

Remarks.—When strumous ophthalmia is complicated, as it often is, by a cutaneous disease upon the face or body, the constitutional treatment exhibited for the cure of the former in many cases first manifests its beneficial action by the subsidence of the eruption. If the scalp be implicated, the ophthalmic affection takes precedence in the process of cure.

The little girl whose case I have just related remained exempt from disease of the eyes for the following six years. In 1848 she consulted me as an eye-infirmary patient for acute corneitis of the left eye, with abscess in the substance of the cornea. She recovered with perfect vision; the iris did not prolapse; the leucoma resulting from the disease was fortunately near to the outer border of the membrane in which it was situated. I did not let out the matter by puncture, as recommended by Dr. Jacob.

[To be continued.]

SCIENTIFIC LECTURES.

HUNTERIAN LECTURES ON THE ANATOMY OF INVERTEBRATE ANIMALS.

BY RICHARD OWEN, F.R.S.,
Hunterian Professor to the College.

This Evening, May 1.—Lecture XXI.—*Mollusca Acephala.* Characters of the Tunicata, Brachiopoda and Lamellibranchiata; their organisation respectively exemplified by that of the Ascidian, the Terebratula and the Oyster. Structure and relations of the bivalve shell. Muscular system. Nervous system and organs of sense. Stomach and trituratiog style. Vascular and respiratory systems. Inhalant and exhalant syphons. Modifications of these and of the shell-valves in the Ship-borer (Teredo). Relations of the compound Ascidians to Polypes, and their propagation by gemmation as well as ova. Generative organs of dicœcious Ascidiæ. Development and metamorphosis of Ascidians. "Alternate generation" of viviparous Salpæ. Dicœcious condition the rule in lamellibranchiate bivalves. Male and female organs bulky but simple: short sperm-duct of males, short oviduct of females: no glandular appendages, and no intromittent organ. Modifications of gills to form marsupial pouches. Development of germ: rotation of ciliated embryo. Metamorphosis of "Glochidium" and other larval forms of bivalves: final purpose of the deciduous byssus.

Tuesday, May 4.—Lecture XXII.—*Mollusca Encephala.*—Characters of the Pteropoda and Gasteropoda. Muscular wing-like lobes of Clio: its digestive, glandular, circulating and respiratory organs. Structure and parts of the shell in Gasteropods. The foot and retractor muscle. Examples of the nervous system. Organs of vision and hearing. Modifications of the jaws and proboscis, of the stomach and intestine. Salivary, pancreatic, and biliary glands. Circulating and respiratory systems. Generative organs of the androgynous Gasteropoda. Combination of testes and ovarium: distinct sperm-duct and oviduct. Glandular appendages of the sperm-duct: intromittent organ. Albuminiparous glands of oviduct: multifid vesicles and spermatheca. Different relative positions of male and female external orifices. Dicœcious Gasteropoda. Development of the ova. Various and singular forms of the ovicapsules. Development of the embryo: phænomena of rotation in ovo. Deciduous nautiloid shells of the embryo nudibranchiata. The "Cirropteron" and other pteropodal larval forms of marine Gasteropoda.

Thursday, May 6, and Saturday, May 8.—Lectures XXIII. and XXIV. —*Cephalopoda.*—Characters of the class and of the two orders Tetrabranchiata and Dibranchiata. Modifications of the shell: its progressive simplification and diminution in the naked Cephalopods. Exceptional character of that of the Argonaut. Nervous system and organs of sense. Calcareous and horny jaws: tongue, ingluvies, gizzard, laminated cæcum and intestine. Sallvary, pancreatic, and biliary glands. Modifications of the circulating and respiratory systems in the two Orders. The ink-bag peculiar to the Dibranchiata. Both Orders dicœcious and oviparous. Parasitic Hectocotylus the probable male of the Argonaut. The single testis; glandular appendages of sperm-ducts. Spermatophora. The single ovarium: oviduct single in some species; double in others: ovidncal and nidamental glands. Female organs of Nautilus. Development of ovum and diverse forms of nidamental capsules; their analogy to the spermatophora in the male. Development of germ; radiated fission of germ-mass. Development of embryo: early manifestation of class-characters; rotation of embryo in the ova of Loligo. External and internal vitellicle. Cephalic umbilicus. Condition and powers of the young Cephalopod when excluded. Concluding remarks on the Invertebrata.

LIST OF SCIENTIFIC MEETINGS FOR THE WEEK.

This Evening,	May 1.	Royal Institution. *Annual Meeting of the Members.*
——	——	Medical Society of London. *Subject:*—Dr. Webster, F.R.S., "On the Health of London." Eight o'Clock.
Monday,	May 3.	Royal Institution. *Subject:*—C. B. Mansfield, Esq., "On the Chemistry of the Metals." Four o'Clock
——	——	Chemical Society. Eight o'Clock.
——	——	Epidemiological Society. Half-past Eight o'Clock.
Tuesday,	May 4.	Royal Institution. *Subject:* — E. Lankester, M.D., "On the Physiology of Plants." Three o'Clock.
——	——	Pathological Society of London. Eight o'Clock.
Wednesday,	May 5.	Royal Institution. *Subject:*—J. Conolly, M.D., "On Insanity." Four o'Clock.
——	——	Geological Society. *Subject:*—Sir C. Lyell, F.G.S., "On the Tertiaries of Belgium." Half-past Eight o'Clock.

Thursday,	May	6.—Royal Institution. *Subject:* — R. Westmacott, Esq., R.A., "On the History and Practice of Sculpture." Three o'Clock.
——	——	Harveian Society. Eight o'Clock.
Friday,	May	7.—Royal Institution. *Subject:* — Prof. E. Forbes, "On the Supposed Analogy between the Life of an Individual and the duration of a Species." Half-past Eight o'Clock.
——	——	Western Medical and Surgical Society of London. *Meeting of Council.* Seven o'Clock. *Subjects for Ordinary Meeting:*— 1. Mr. Keen, "On a Case of General Subcutaneous Cancer." 2. Dr. Traquair, "A Comparative View of the Various Methods at present employed in the Treatment of Rheumatic Fever." Eight o'Clock.
Saturday,	May	8.—Royal Institution. *Subject:*—Prof. Faraday, "On Points Connected with the Non-Metallic Elements." Three o'Clock.
——	——	Medical Society of London. *Subject:*—J. T. Brown, Esq., "On the Treatment of Ovarian Dropsy by a New Method of Operation." Eight o'Clock.

TERMS OF SUBSCRIPTION.

Twelve Months (pre-paid) stamped for post £1 10 0
Six Months (do.) 0 16 0

Regularly transmitted by Post throughout Great Britain, and to the most distant of the British Colonies.

Post-Office Orders to be made payable at the Post-Office in Coventry-street to Mr. James Lucas, *46, Princes-street, Soho.*

TO ADVERTISERS.

Terms for advertisements (which should be sent to the Office before two o'clock on Thursday):—

For seven lines (or less) 6*s.* | *Each additional line,* 6*d.*

TO SUBSCRIBERS.

Portfolios for holding the Numbers of the current Volume, 2*s.* 6*d. each, may be had by order of any Bookseller.*

Cases for binding the Volumes in cloth, gilt lettered, price 2*s.*

Orders should be given, without delay, for back Numbers or Volumes that may be required to complete Sets.

The TWO VOLUMES for 1851, *price* 34*s. cloth.*

Medical Times & Gazette.

SATURDAY, MAY 1.

THE COLLEGE OF PHYSICIANS.

We gave last week an abstract of the proposed new Charter of the College of Physicians. The following are its chief features:—

The sphere of the College is to extend through England and Wales; all physicians will be compelled to join it, by means not specified in the Charter, though reference is made to them; the class of extra-licentiates will be absorbed into the new class of members; all present practising physicians (not being fellows or licentiates) will be admitted to the membership; future physicians must undergo examination; members will become fellows by examination or election.

Of the utility of these alterations there can be no question. The present Charter is both liberal and fair; it aims at a more perfect organization, and we are bound to say, that it appears to attain it. After a very careful examination of the several clauses, we see nothing to object to in the filling up of the details, except in one or two cases. We should wish to see the method of election of the several officers a little more democratic. The general body of Fellows appear to have, except in the case of the Council, no power of initiation. They propose the Council apparently, but then deliver themselves hand and foot to their nominees. The Council propose the President and the Censors; the President nominates the Vice-Presidents. In most societies and corporations, every member of the electing body has power to propose a candidate for any office, and this method has great advantages.

Another point to which we make some objection is, the utter exclusion of the members from all share in the government. Why, indeed, is it necessary to keep up this distinction of fellows and members? Or, admitting that the latter is a good probation, before a young physician is admitted to the higher honours of the fellowship, could no means be found of connecting, in some way, the members more closely with the College?

Again, supposing the fellows to be created on account of their high acquirements, why not allow to each a vote? Why limit the privilege of voting to those resident in London or its vicinity? for it is evident, that to compel personal attendance when a vote is to be given, is really to exclude the great bulk of the provincial Fellows from taking part in the management of the affairs of the College. Still, even with these drawbacks, the new Charter will be a great gain, a manifest benefit to all physicians. Time, too, will cure most of, if not all, these faults. The door is to be opened widely, and it is strange if the College be not after a little while thoroughly ventilated.

There is, however, one clause which we are sorry to see the College have inserted. We cannot see why the College should have the power of granting the degree of M.D. to any candidate who has reached forty years. Why not equally give the College the power to grant degrees at any age? Why not, in fact, make of the licensing College a graduating University? What is there in the age of forty so magical, that all usual rules must give way to it? "At forty, a man is either a fool or a physician" is the old saying, and the College seem disposed to seriously carry out the proverb. We cannot doubt but that the Universities will oppose this attempt to make the College of Physicians a refuge for senile would-be graduates.

The only argument which presents itself to our minds in favour of this clause is, that a general practitioner, on reaching the age of forty, might easily, if he wished, pass into the higher grade of the Profession. But there is even now no real difficulty in doing this; and, in fact, a great number of general practitioners are from the first graduates of one or other University. This trifling advantage would not compensate for the disadvantage of having another body authorised to grant degrees, added to the too numerous ones already in existence.

Putting this aside, we have no hesitation in expressing our hope, that the College may obtain their Charter. We trust, when they have got it, they will take care to let in no homœopathists, and then they will really do the physicians throughout the country a great service, by drawing a line which the public will be able to appreciate, between legitimate and irregular practitioners.

NEW CHARTER OF THE COLLEGE OF SURGEONS.

In December last we laid before our readers in full the Draft Supplemental Charter of the College of Surgeons. The College has now received a new Charter, identical with that Draft. The following are its chief points:—

The Council may elect, as a Fellow, without examination, now or hereafter, any member of the College of fifteen years' standing who was a member of the College before 1843, *i. e.*, before the date of the last Charter, provided "that he does not sell or supply drugs or medicines otherwise than in the due exercise or practice of his profession as an apothecary," that he produce a certificate to that effect

signed by six Fellows of the College, by two Fellows and the superintendent medical officer of the military department, or by two Fellows and the Governor of any of the Colonies; and that he pay ten guineas to the College. The Council may also admit, without examination, to the Fellowship, yearly, on the payment of the same sum, any two members of the College of twenty years' standing, as well as the Fellows, members, and licentiates of any other College of Surgeons in the United Kingdom.

The members of Council are to be elected from the Fellows of twenty years' standing, not at the date of their election practising as apothecaries. Candidates for a seat in the Council are to transmit their own names to the Secretary of the College, with a "nomination, signed by six Fellows;" the Council are then to announce by advertisement the names of the candidates, and from these the Fellows are to select at a meeting summoned for that purpose. Three members of Council retire annually, but are eligible for re-election. The ordinary examiners are to be appointed for five years by the Council, who are further empowered to appoint "not less than three persons" to the examiners in midwifery.

This Charter has been, as we anticipated, received on the whole with satisfaction by the Profession, and, it must be confessed, is a great improvement on the last. Although not all we could wish, yet it confers a great benefit on the Profession. The cause of medical reform is advancing—slowly, it may be, but none the less surely. The monster injustice of the Charter of 1843 must now be repaired. The members of the College fairly entitled to the Fellowship are to receive it; surgeons are to be in examined midwifery; provincial surgeons may, henceforth, enter the Council; and the mode of electing the members of Council would, if there were no country Fellows, be unexceptionable. We have sought earnestly for an explanation of the exclusion of the country Fellows from the exercise of their privilege of voting at the election of the Council, but we have sought in vain, unless it be that the existing Council are desirous of retaining more than their legitimate influence in the choice of their successors and colleagues. Ultimately, the Council will have to yield this point.

To repeat our own words, we receive the Charter, then, as an instalment towards the settlement of the question of medical reform, and, as such, we accept it with gratitude, determined, at the same time, to demand the rest, until the full debt be duly discharged.

THE PHARMACY BILL.

This week has been an important one in the history of the new Pharmacy Bill. The Scottish Corporations, who, up to this time, have shown an extraordinary apathy in regard to a measure deeply affecting their interests, have at length been roused, and are now taking vigorous steps in regard to their existing rights.

On Monday and Tuesday, the Select Committee took the evidence of Fellows of the Royal Colleges of Physicians and Surgeons of Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow. The general tenor of that evidence may be inferred from a document now before us.

The College think it might be for the public good that druggists should be examined, registered, and distinguished by an honorary title; at the same time, they object to the institution of a new Corporation, which shall enjoy exclusive privileges in any department, and the establishment of which would still further comprehend the general question of medical reform. They suggest further, that it would be a retrograde movement to confer a monopoly on any body whatever; that they have themselves ceased to exercise their powers over druggists, because they found public competition a better check than any they could devise; that they cannot give their sanction to the formation of a Board in London, to which the nomination of the parties who are to carry out the objects of the Bill in Scotland are to be intrusted; that they "observe with regret that it is proposed to enforce the provisions of this Bill by inflicting penalties for breaches of its enactments;" "and are of opinion that no penalty should be inflicted except in the case of parties fraudulently assuming a title to which they have no legal claim;" that they decidedly object to the privilege of being registered as Pharmaceutical chemists being withheld from members of the Medical Profession; and suggest that the following words should be added to Clause XX., viz., "and that all persons who may now be, or may hereafter become, entitled to practise, under the licence of any of the corporate bodies in Scotland examining on materia medica and pharmacy, shall be entitled to carry on the business of pharmaceutical chemists;" and, finally, they object very decidedly to the arrangement proposed by Clause III., permitting of voting by proxy at the meetings of the Society.

It will be seen that the views of the Royal College of Physicians of Edinburgh agree in the main with those we expressed in our Article of March 6th, on "The New Pharmacy Bill;" and their efforts to oppose it will be fully appreciated by the great body of the Profession.

Drs. Rinton and Alexander Wood, from the College of Physicians; and Drs. Combe and Gairdner, from the College of Surgeons of Edinburgh; and Dr. Watson, from the Faculty of Glasgow, had an interview with the Home Secretary on Tuesday on the same subject.

It is a satisfaction that, in one part of the kingdom at least, the Royal Colleges see the injurious bearing of Mr. Bell's Bill on themselves and on the Profession.

HILL-TOP *VERSUS* VALLEY-BOTTOM WATER.

We have received an important Memorandum, just issued by the Sanitary Association on the Metropolitan Water question. This document refers to a vast mass of chemical and engineering evidence, in proof of the superior quality, ample quantity, and moderate cost, of the water obtainable from the barren uplands of Surrey, as compared with that which the monopolist water companies pump up from the sewage-tainted Thames. It shows that *hill-top* water is invariably purer and softer than *valley-bottom* water; the former being the pure sun-distilled rain-water, taken as near as possible to its source in the clouds; while the latter is the same water, taken after it has washed the surface of manured fields, and of cattle-dunged roads and streets, besides receiving the drainage of the valley-population, which numbers, in the case of the Thames, (even above Teddington Lock,) more than three quarters of a million. We have no hesitation in confirming the third paragraph of this very able and luminous paper; which sets forth the insalubrity of such tainted river water, especially in hot epidemic weather, when the activity of fermenting matter becomes so intense, that water not visibly impure, or even clouded, may yet cause violent diarrhœa, dysentery, etc. For these reasons, we hold the river Thames, even when in its clearest and purest condition, a far less safe and suitable water source for the Metropolis, than the pure sand-springs of the Surrey hills; and we know we shall be borne out by the whole Medical Profession, in

demurring to the statements of the chemical witnesses who were last week examined before the Water Committee, and who pronounced the organic contamination of the Thames too small in *quantity* to affect health. Those gentlemen are, doubtless, very accomplished analytical *chemists*, but they betray an entire ignorance of the physiological and pathological bearings of the water question; which can only be elucidated with due authority by well-informed and experienced medical men. It argues, indeed, no slight neglect on the part of the Commons' Water Committee, that it has called so little authoritative professional evidence to prove the superior salubrity of soft over hard water, and of pure over sewage-tainted water, for potable and culinary use. Dr. Prout, it is well known, recommended the use of distilled water to dyspeptic patients; Dr. Leach, of Glasgow, bears witness to the marked decrease of dyspeptic and urinary disorders in that town since a softer and purer water has been introduced; and Mr. Simon, of St. Thomas's Hospital, who unites the highest professional attainments with great sanitary experience as officer of health to the City, not only confirms these views in a recent Report, but says truly, that they are the general opinions of the Medical Profession. To those opinions we shall endeavour to give effect, by supporting the proposed introduction of the pure soft water from the Surrey sands, and by opposing the threatened perpetuation of the monopolist companies, determined as they appear, in the teeth of all evidence, to pump up the hard and foul Thames water, and sell it to the population at four times the proper price. Between *hill-top* water, pure and cheap, and *valley-bottom* water, costly and foul, our choice is made; and we shall lose no opportunity of demanding, on behalf of the Profession and the public, the abandonment of the condemned Thames river supplies, in favour of the sparkling sand-spring water from the Surrey hills.

UNPAID MEDICAL OFFICERS.

In another part of our present Number will be found a letter addressed by the Assistant-Physicians and Assistant-Surgeons of the London Hospital to the Governors of that Institution. It is an ably-written document, and contains in plain but forcible language a statement of the injustice of employing assistant medical officers without remunerating them in some measure for their labours. It cannot fail to command attention; and we believe that it will as certainly lead to the object its authors have in view. For years the junior officers of the majority of our metropolitan hospitals toil on without deriving, directly or indirectly, the slightest compensation for their services. Many of them even grow grey ere they attain the posts to which they aspire; while the senior medical officers, as the writers of this letter state, necessarily absorb all the practice arising from hospital connexions, and receive the fees paid by the pupils. The members of no other profession are guilty of the folly of working the best part of their life without fee or reward; and we trust the days are numbered in which medical men will commit so gross a blunder.

Dreadnought Hospital-ship.—The anniversary dinner of the Seamen's Hospital took place on Monday last, on which occasion it was stated, that upwards of 65,587 patients, of whom nearly one-half were foreigners, had been relieved since its establishment; and that, during the past year, 2242 had been admitted. Mr. Hume, the Chairman, appealed so successfully to the meeting, that 1350*l.* was subscribed after dinner.

Sir William Burnett, M.D., F.R.S., K.C.B., Director-General of the Medical Department of the Navy, is on a visit of inspection to the medical establishments attached to Portsmouth.

REVIEWS.

The Past and Present State of Intramural Burying-places; with Practical Suggestions for the Establishment of National Extramural Cemeteries. By G. A. Walker, Surgeon, etc. Pp. 50. Longmans and Highley.

A bold and uncompromising exposure of the great evils to which men "in populous cities pent" are exposed by the grave-yard nuisance. Mr. Walker's name is as closely identified with the cure of this evil as that of Howard with the improvement of prisons, or of Conolly with the treatment of the insane. He has rendered a great and lasting service to his fellow-countrymen; and this pamphlet, which not only points out the evil, but shows the remedy, we cordially recommend to the perusal of our readers.

The Hand; its Mechanism and Vital Endowments, as evincing Design. By Sir Charles Bell. Fifth Edition, with Woodcuts. 8vo. Pp. 128. London: J. Murray. 1852.

This book, we need not say, is one of the Bridgewater Treatises, and one of the most interesting and admirably written of the series. The fourth edition was published in 1837; the present is edited by Mr. Alexander Shaw, who has enriched it with notes furnished by its author to Lord Brougham's edition of "Paley's Natural Theology," and extracts from "Animal Mechanics." These additions occupy about eighty pages. Mr. Shaw has performed his task with great judgment. The work is beautifully "got up,"—paper, type, and woodcuts unexceptionable.

The Philosophy of Living. By Herbert Mayo, M.D., formerly Senior Surgeon to the Middlesex Hospital, etc. etc. Third Edition. Pp. 282. London: J. W. Parker. 1851.

"The Philosophy of Living" was written, says its author, at the suggestion of an eminent publisher, who desired to have a book to the title. It is addressed to that portion of the public whose circumstances allow them to live where and how they choose. "It is," Dr. Mayo writes, "to be viewed rather as ancillary to the advice of the fashionable physician, than as conveying lessons of sanitary regulation and provision for the poorer classes." Dr. Mayo's style is excellent, and his philosophy sound.

The Vegetation of Europe; its Conditions and Causes. By Arthur Henfrey, F.L.S., etc. etc. Pp. 387. John Van Voorst. 1852.

This work is one of a series—"Outlines of the Natural History of Europe"—in course of publication by Mr. Van Voorst. It is only during the last half century that botanical geography has been studied as a special subject. At first it was supposed that a difference in the temperature of different countries was sufficient to explain the differences observed in their vegetation, but more careful observation showed this to be an error. A variety of atmospheric states, and the chemical and physical conditions of the soil must be considered, in order to explain apparently anomalous facts. But these are insufficient; and Mr. Henfrey says—

"Countries have become populated with plants partly by the spreading of some special kinds from centres within those countries where they were originally exclusively created, and, while these have spread outwards into the neighbouring regions, colonists have invaded and become intermingled with the indigenous inhabitants."

He then proceeds to consider the general influences on the distribution of vegetation, and special influences on the distribution of vegetation, and, subsequently, the characteristics of the vegetation of the countries of Europe.

This work will be found a very valuable acquisition to those interested in the subject on which it treats.

A Treatise on the Diseases of the Chest; being a Course of Lectures delivered at the New York Hospital. By John A. Swett, M.D., Physician to the New York Hospital; member of the New York Pathological Society. 8vo. Pp. 585. New York: Appleton and Co. 1852.

This work consists of twenty-two lectures on Diseases of the Lungs, and thirteen on Diseases of the Heart. They

were delivered ten years ago, and published at that time in a New York weekly journal. Since then, Dr. Swett says, he has carefully revised the whole subject, and added the experience of ten years' hospital and private practice. These lectures prove Dr. Swett to be a good practical physician; one who has seen much, and paid considerable attention to his cases; but we cannot recommend them very strongly to the notice of the Profession in this country. They are decidedly inferior to the standard works on the same subject we already possess. In proof of this assertion, we shall point out some of the defects in the first lecture, which is headed thus:—"Physical Signs of Pulmonary Disease." There is here no mention of friction-sound, or of friction fremitus, and, strange to say, neither is referred to when describing the physical signs of pleurisy. Jerking respiration is said to be always due to the deposit of tubercles in the lungs; vocal fremitus is scarcely mentioned; the difference of its force on the two sides is unnoticed; and in the chapter on Pleurisy vocal fremitus is not even referred to. Cavernous breathing, as distinct from amphoric, is affirmed to indicate unequivocally the presence of a cavity; and œgophony is spoken of as a common sign. These are a few of the faults of omission and commission in the first lecture; many of those in the subsequent lectures are yet more important.

UNPAID MEDICAL OFFICERS.

TO THE PRESIDENT, VICE-PRESIDENTS, AND GOVERNORS OF THE LONDON HOSPITAL.

My Lords, Ladies, and Gentlemen,—We, your assistant medical officers, have long been impressed with the propriety of our professional services rendered to your Institution meeting with some adequate recognition. Our opinion has of late been so fully borne out by the powerful advocacy of the Medical Press, and by the conduct of the Governors of several medical institutions, that were we any longer to remain silent on the subject, we should appear as a consenting party to what we regard as a manifest injustice.

Many of those we address are unaware that our responsible and onerous duties are performed without any remuneration. These duties require attendance at the hospital at definite periods during every week, and the acting in place of our senior colleagues, as occasion may require. They involve much time taken from the most valuable part of the day, considerable mental anxiety, and bodily fatigue. As evidence of such being the case, we may mention, that the average annual number of patients under the treatment of your assistant-staff has, during the last ten years, amounted to 15,431—the largest number being, in 1849, 20,614.

We feel that the gratuitous performance of these laborious duties has grown up under peculiar circumstances, and is at variance with the spirit and intention with which your important charitable Institution was originally founded.

In the early days of the London and other metropolitan hospitals, the remuneration of the physicians and surgeons was provided for directly by the fees paid by pupils, and indirectly by private practice, which such a position soon established. In the course of time, however, the medical requirements of the several hospitals having much increased, assistant officers were appointed, and it must have been thought at the time that the remote prospect of promotion to seniority would be ample compensation.

A full and fair discussion of the case, which the limits of a letter scarcely permit, would, we are confident, fully demonstrate the fallacy of such a conclusion. In the capacity of Governors, you very properly require that your assistant medical and surgical officers should hold a high professional rank, (to obtain which requires a prolonged and very expensive preliminary education,) and practise as consulting physicians and surgeons, the least remunerative career by far during early life, the senior medical officers almost necessarily absorbing the practice arising from hospital connexions. Hence it follows, that your assistant officers who are called on to sustain their professional and social position, perform during the best years of their life the important duties of your hospital without any adequate acknowledgment. Should their health give way, or other unforeseen circumstances arise, as has more than once occurred, you as Governors can scarcely call to mind without regret, that many years of anxious toil have been expended by the members of your assistant-staff in the service of your Institution, without that fair remuneration which not only generosity would suggest, but even justice may claim.

Some such considerations as the above have within the last few years induced the Governors of several hospitals, viz., of Guy's, St. Thomas's, St. Bartholomew's, and the Royal Free Hospital, to give an annual stipend to their assistant medical officers. It may be further stated, that the Governors of St. Luke's, Bethlehem, and the Dreadnought Hospital, and those of no less than ten metropolitan dispensaries, do the same.

We cannot but think that the Governors of the London Hospital will feel the force of these statements, and that, emulating as they do the other hospitals of the Metropolis in their edifice, their method, their arrangements, the number of their patients, and the magnitude of the benefits conferred on suffering humanity, they will not be less anxious than the Governors of similar establishments to do justice to those through whom the most important of these results are in a great measure obtained.

It has been suggested, that the insufficiency of the resources of your hospital to meet the heavy demands on its funds may be offered as a plea for your not remunerating your medical officers; but the liberal manner in which the services of all your other officers are acknowledged forbids the belief in the validity of such an objection.

After much consideration, we have thought it proper to appeal to the general body of Governors, rather than to your Committee, because, having been elected by you, we feel that it is only through you that this act of justice can be done.

Supported by arguments, by the Press, by precedent, by the opinion of our senior colleagues, and a confidence in your sense of right, we have felt the propriety of bringing the subject thus before your notice, and of claiming for it your full consideration.

We have the honour to be, my Lords, Ladies, and Gentlemen, your faithful and obedient servants,

Patrick Fraser, M.D.
Herbert Davies, M.D.
Nicholas Parker, M.D.
George Critchett, F.R.C.S.
Nathaniel Ward, F.R.C.S.
John Cawood Wordsworth.

GENERAL CORRESPONDENCE.

THE CASE OF MR. PASCOE.

I.

[To the Editor of the Medical Times and Gazette.]

Sir,—I pursue the subject of my evidence in Mr. Pascoe's case, after reading in your Number of the 24th instant your observations upon my first letter and five other communications condemnatory of my opinions; and before I again enter upon the question, as a medical one, upon the admissibility of savine as a therapeutic means, let me observe, that one of our two county papers, the *Cornwall Gazette*, which is conducted and edited by two medical men of reputation in the county, declines to enlist itself in opposition to Mr. Pascoe's sentence, upon the expressed conviction, that proof had been adduced to warrant the verdict.

I pass by your two correspondents, who have had the taste to conceal their names, merely noticing of "Subscriber and M.R.C.S.," that he appears to be the only one of the five who has been a prescriber of savine, while I cannot find from the three gentlemen who have entered upon this subject, that they know by their own practice and experience more than myself upon the action of this substance.

I am ready to entertain Mr. Lowe's courteous letter, and to comply with his invitation to reason upon points.

He assumes that I had stated in evidence, that the savine had produced abortion. So far from that, it was distinctly seen that this drug had produced no such effect; and Mr. Lowe must be acquainted with the fact, that it is not necessary, in order to complete the offence with which the prisoner was charged, that the drug administered should have the intended effect.

I stated, that if abortion did not follow within fourteen days from the irritating effects of savine, it (the abortion) could not be ascribed to savine, and, further, that the dose prescribed by Pascoe was, in my opinion, calculated to produce purging, etc., but no consequences to the woman of a dangerous kind or degree.

And now let us take the point of the possible, or even probable, effects of fourteen drops of oil of savine taken daily for the space of a month. I admit that the authority of Ashwell, given by Mr. Lowe, upon the dose of the oil, is against me; yet it should not be overlooked, that he states its use to be much restricted at present; but when I find him giving the authority of Brande, who says, "it should be always administered with the greatest caution,

lest it induce inflammation," I cannot see that this authority favours his views.

If Hooper was successful with the powder of savine, in doses of a scruple, or at most a drachm, he succeeded with a form of the drug known, or said by Dr. Paris, to be rendered comparatively inert, by the drying process dissipating its active principle, the essential oil.

But supposing a drachm of the powder to retain all the active qualities of savine, Hooper, or any other person, in prescribing this, his maximum dose, twice a-day, had, according to the authority before used by me, ordered not quite the strength of two drops of the oil, if Dr. Royle's statement of the proportion of oil obtained by distillation indicates anything like the real proportional composition of savine. In justice to Mr. Lowe, I grant that Pereira's testimony is favourable to his statement; but in justice to myself, too, let me add, that Pereira's formula for the infusion, found in Royle's Materia Medica, had influenced my judgment. Mr. Lowe, who does not declare that he has used savine, will pardon me when I affirm, that from my reading of the substance, I was as well acquainted with the fact as he was, that when miscarriage is the effect of savine, it can only be at the risk of the woman.

I do not learn anything from the authority of Dr. A. T. Thomson, when I find him instructing us, that "at all times the internal use of savine requires caution;" and when I return to Dr. Paris, who says, that Cullen's opinions had brought it into disrepute, although he (Dr. Paris) had found it useful in amenorrhœa in females of relaxed systems; and when, in addition to this, I find Dr. Forbes, in his review of Paris's last edition, upon the subject of ergot as an emmenagogue, stating, that, in his opinion, ergot is nearly as uncertain in its operation upon the menstrual secretion as other emmenagogues, but, as it is productive of no injury to the constitution, it may be adopted, I am not yet satisfied that Mr. Lowe, Mr. Irving, or Dr. Barker would, if ever they use savine, prescribe fourteen drops of the oil to be daily taken for a month, without watching their patients.

And, after all, I ask this question—Can they find Thomson, Pereira, Brande, Ashwell, or any other authority, suggesting that a respectable and discreet medical man would prescribe savine in any form or dose, without previously ascertaining that the patient was not pregnant?

It is not enough for me to find my opinions opposed, through your Journal, by five, or fifty, or five hundred medical men, like myself, of obscure or ordinary standing, after the positive, and possibly premature judgment uttered by yourself. Let this case, with all its points, be fairly put to the judgment and the decision of medical authority; and, after that, it will be either for me to show to the Profession, that I have sufficient moral courage to admit that my testimony has been given in error, or for you to retract, to some extent at least, your declaration, that William Hamlyn Pascoe has been convicted upon "medical evidence which is utterly worthless and untrue." I am, &c.

WILLIAM MOORMAN, jun., L.A.C., M.R.C.S.

St. Columb, Cornwall.

P.S. Since writing the above, I have received an anonymous letter, dated at Bristol, and signed "Humanitas," upon the subject of my evidence at the late trial of Mr. Pascoe, and calling upon me to communicate with the Secretary of State, and to admit that my evidence has been erroneous.

The writer accompanies this application with expressions somewhat invective, and with the declaration that he, ignorant of the existence of pregnancy, has in two instances known abortion to follow his administration of savine.

If this, coming from an anonymous writer, can be taken as a fact, it shows at least that savine is a drug which ought to be discountenanced. The writer, whoever he is, will see that I am by no means so tenacious of my opinions as to turn from reasoning; but I cannot comply with the sudden and offensive application of any man, who, from any cause, is afraid or ashamed to subscribe his name.—W. M.

II.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have read with exceeding care, the remarks which have appeared in your Journal with reference to the above important trial, and it is not without feelings of deep regret, similar to those which you yourself have expressed, that I think it right to follow in your footsteps, and to criticise freely the medical evidence of Mr. Moorman.

I shall dwell, in my observations, on the evidence of Mr. Moorman at the trial, and on his letter in your last Journal, at one and the same time.

The first thing, then, which strikes the reader, on looking at the particulars of the evidence, and at the letter, is the great want of knowledge on the subject of that evidence, which Mr. Moorman shows himself to have possessed at the time of giving it. Speaking of the therapeutical action of savine, he admits, "that he had never used the drug himself, nor did he know any other practitioner who had used it." Practically, therefore, it is evident that Mr. Moorman knew nothing whatever about savine. Again, in information from written authorities as to the action of savine, Mr. Moorman seems to have been miserably deficient. Twenty English writers at least, to say nothing of foreign, and of the ancient Greek ones, commencing with Hippocrates, have spoken on this subject, and expressed various opinions: and yet, as far as we are able to learn, he (Mr. Moorman) contented himself by consulting two authors only; thus making it obvious that his acknowledged want of practical information on the matter was in no way compensated for by his theoretical information.

That this criticism may not seem too severe, allow me, Sir, to bring forward two or three of Mr. Moorman's statements, and to try them, partly on their own testimony, and partly on the written opinions of the various writers who have spoken upon the properties of savine.

1st. Mr. Moorman asserts, "that, in his opinion, fourteen drops of oil of savine per day would produce the peculiar effects of savine, such as irritation, or purging, or inflammation probably of the small intestines, and that, as a consequence of this, miscarriage might result." He also states, "that no man of competent skill would, in his opinion, use it in such quantities, unless the object was abortion." Now, the impropriety of giving any such evidence as this, on the part of Mr. Moorman, at once becomes apparent, when the statements noted above are referred to. "Mr. Moorman has never given the drug savine, nor does he know any practitioner who has given it." He is ignorant, in fact, of its effects, either for good or for evil! What right, then, has he to affirm on oath, that the drug in question is capable of producing any such effects as those he names? Mr. Moorman can have no trustworthy knowledge concerning that of which he has neither heard nor seen; neither has he any more right to assume, that savine, in the doses named, might not be used with all safety for the legitimate purpose of causing the menstrual flow, than he has to assume, that in such doses, it could only be used for the illegitimate purpose of producing abortion. But, more than this, had Mr. Moorman inquired into the matter, he would have found, that no man of competent skill would employ savine, in any dose at all, for the purpose of producing abortion, since he would have discovered that which is the fact, viz., that savine, neither by direct nor indirect agency, possesses much power to produce abortion. He might have learned, by the merest glance at the works of those two illustrious British medical jurists, Dr. Alfred Taylor and Dr. Christison, that abortion from the effects of savine is the exception rather than the rule; that a pregnant woman has been known to take the oil of savine in doses of 100 drops daily without its effecting abortion; that all the other effects of savine, such as intestinal irritation and purging, may be produced during pregnancy, and yet no abortion result; nay, that a woman so situated may die from the effects of this drug, and remain undelivered!

2ndly. "Mr. Moorman affirms, that savine is discountenanced by the Profession now a days, and that no practitioner less skilled than himself would use it as an emmenagogue."

This assertion is at once so gratuitous and contrary to all fact, that one is astounded to know that it ever passed from the lips of a qualified medical man. Your correspondent, Mr. Lowe, has shown this in the list of authors given in his letter. To this list I would add the authority of Dr. Anthony Todd Thomson, who, in an article on Emmenagogue in the "Cyclopædia of Practical Medicine," thus remarks: "In whatever manner it acts, savine or its oil is well adapted for cases of amenorrhœa connected with a feeble state of the constitution, and a languid circulation." Beck, also, in his "Medical Jurisprudence," as "an effective emmenagogue." Nor did Cullen, to whom reference has been made, deny its action as an emmenagogue; he simply said, that, in consequence of its heating properties, he had not ventured to use it as such.

I may add, moreover, that although I have never used savine myself, yet I know gentlemen who do, and who have long used it, and who consider it an efficient remedy for bringing on the menstrual flow.

3rdly. Mr. Moorman gives an opinion, "that the dose of savine administered by Mr. Pascoe (14 drops daily) was very large, and that such large doses were not used in old practice."

These statements are as gratuitous as the last were. Thus, Dr. A. T. Thomson gives the dose of savine as, Powder, 5 to 10 grains; oil, 2 to 6 minims. Christison, powder, 10 to 15 grains; oil, 2 to 5 minims. So much for modern authority. On referring

to more ancient authors, I find Dr. Home, of Edinburgh, in his Clinical Reports, (written in 1783), to which allusion has been made by Pereira, saying of savine, "Authors mention a drachm" (of the powder) "as a proper dose. I gave generally but half that quantity, and have found it useful and safe." Then follow the reports of five cases of amennorrhœa in which savine was employed; in three with success. (Third Edit., p. 420.)

As a further proof, that the old practitioners did not consider savine a very powerful remedy, I will just refer to the article "Sabine," or "Savine," in Dr. Stephen Blancard's "Physical Dictionary," a book published in 1726, and which was a first authority in its day. The writer here, after describing the well known properties of savine, states in reference to its dose, thus:—"A spoonful of the juice of it mixed with milk, and sweetened with sugar, has been given with great success to children with worms, and it is an extraordinary medicine, and in no way dangerous."

There are still other matters, Sir, with reference to this medical evidence, which have an important bearing on the disagreeable position in which it, and the conviction it led to, place every practising member of our Profession; but my hand is checked from writing on this question, by the knowledge that I am already guilty of trespassing too far on your columns. It will be observed, that in what I have said above, no speculations have been entered into with reference to the moral guilt of Mr. Pascoe. I am convinced myself, that the trial of Mr. Pascoe proves nothing against him, and I sincerely hope that the members of the Profession will unite to memorialise the Secretary of State for a fresh inquiry on his behalf. It has been my object, however, only to deal with Mr. Moorman's statements, as forming the evidence of a scientific man, to show that his own admissions ought to have been sufficient to have shut him out of court, and that his assertions have no accuracy left in them when tried by the experience of others.

Mr. Moorman says that his evidence was not hastily delivered; so much the worse for him, in that it exhibited such grievous ignorance. He says it was conscientious; and that he believed what he said to be true, at the time of the trial, I quite admit. But surely it was not very conscientious of him to give sworn opinions on a subject which he admits himself to be unacquainted with, and to make blind statements directly contradictory to the opinions of others who have carefully studied the matter, and the benefit of whose labours he might have obtained by the merest possible exertion.

One word more. Mr. Moorman, in his letter, observes,—"that should his opinions be held erroneous, no one would more deeply regret than himself the effects of those opinions." Now, this admission (notwithstanding all my previous criticisms) I do greatly admire; it is very atoning; it is nobly spoken; and it does as much credit to Mr. Moorman's heart as his evidence does discredit to his professional knowledge, and to his abilities as a medico-legal witness. I am, &c.

Mortlake. BENJAMIN W. RICHARDSON.

III.

[To the Editor of the Medical Times and Gazette.]

SIR,—Fearing lest any of your numerous readers should imagine that the Medical Profession in this county take no interest in the unhappy fate of poor Pascoe, I beg to apprise you that I have the honour (for I consider it such) to have appeared first in public on his behalf. Herewith I send you a copy of a letter of mine, which I forwarded to the *West Briton* newspaper, the most widely circulated of our local papers. I am much gratified that the object I had in view has been so far answered that it has been the means of attracting a vast deal of attention to the subject, as I am convinced of from a number of letters I have received both from medical men in this neighbourhood, altogether unknown to me, and also from London, from gentlemen who are at the head of the Profession. I feel personally greatly indebted to you for the able leader given two weeks since in the *Medical Times and Gazette*, and that that very article "has been heard even in St. Columb." I shall feel obliged by the insertion of the before-mentioned letter of mine in your next Number. I have also sent you Mr. Moorman's reply to mine, which you can also insert; from which you will perceive, that his letter, given in your last Number, he intended as an answer to mine.

I think Mr. Moorman's letter, published in the *Medical Times and Gazette* of Saturday, calls for a few observations. And at the outset, I beg you to bear in mind Mr. Moorman's statements, given on oath, "that no medical man would give savine for any legitimate purpose." He now says, that his answers were given under the following considerations:—

I. His never having given it or known it given. I very much fear that this has led him into very serious errors. Does Mr. Moorman believe that he has given, or known others give, all the remedies used in medicine?

2. Dr. Royle's Manual; an authority which, according to Mr. Moorman's own showing, entirely condemns his statement. Speaking of savine, he says, "In small doses it is stimulant and emmenagogue." I quote from Mr. Moorman's own letter.

3. Dr. Paris's Pharmacologia, who states, "that Dr. Home, of Edinburgh, was in favour of savine as an emmenagogue, but that the adverse opinions of Cullen had brought it into disrepute." I again quote from Mr. Moorman's letter.

Mr. Moorman then adds, "These, then, were the authorities upon which I formed my opinions." What! Dr. Royle and Dr. Home, who speak of savine as an emmenagogue! Did they ever give it for "any legitimate purpose?" Is it possible? The very authorities quoted by Mr. Moorman knock the ground on which he endeavours to stand from under him.

I do not think Mr. Moorman has acted fairly in giving Dr. Cullen, who flourished so many years ago (he died February 5th, 1790), when he despises "Hooper's Dictionary," the last edition of which was published about three years since, and, according to Mr. Moorman, is "an old-fashioned book!"

In his letter, Mr. Moorman says, "If by the majority of the Profession (speaking of his opinions) they are held to be erroneous, no one could more deeply regret than myself (qy. Pascoe) the effects of these opinions, or more earnestly desire an application to the Secretary of State for a reconsideration of the prisoner's case;" and I now call on Mr. Moorman to send in a statement on Pascoe's behalf to the Home Office, in his own individual capacity, in deference to the opinions of Drs. Royle and Home, quoted by himself; as likewise to the opinions of Hooper, A. T. Thomson, Churchill, Locock, Beck, Christison, Pereira, Ashwell, Bovin, Brande, Ballard, Garrod, and Chapman.

As Mr. Moorman has made some remarks on the disposal of the child, I propose giving you a statement of the custom prevalent in this locality regarding the burial of still-born children. The sexton is sent for, or the child is carried to his house after dark by the nurse or some friend; so that nothing unusual occurred in the interment of this child, and Mr. Pascoe did not go out of the beaten track.

I am very sorry, for Mr. Moorman's sake, that he has alluded to the former trial of Pascoe for manslaughter, as it does somewhat savour of a strong animus. In that case, as well as my memory serves, and I certainly speak under correction, it was supposed that Pascoe gave a man laudanum, in mistake for tinct. rhei. Whether such was the case or not, I do not know, but the evidence broke down altogether for this reason: the contents of the man's stomach were saved and given to a duck, which lived, and sustained no injury from the dose. I am heartily sorry to mention these things; but, as Mr. Moorman has unnecessarily dragged them into this correspondence, I feel bound to state all I know, and defend an unhappy brother, who is immured within the walls of a gaol, incapable of defending himself. Sorry to have taken up so much of your valuable space, I now conclude, hoping that the representations of the Medical Profession in the right quarter, will produce the desired result. I have forwarded letters to the Home Office and to Mr. Justice Erle. I am, &c.

ANDREW HINGSTON, M.R.C.S., L.A.C.

Liskeard, Cornwall.

(COPY.)

[To the Editor of the West Briton.]

SIR,—In reply to Mr. Andrew Hingston's letter to you on the subject of my evidence, as given at the trial of William Hamlyn Pascoe, I beg to say, that I am quite certain Mr. Hingston has a right to question the opinions of myself or any other person upon medical points; but I am not so sure that it becomes him to accompany his opinions with imputations upon the character of another man who may hold opinions adverse to his own. I assure him, too, that my evidence was not given without first consulting authorities upon the subject; and as I consider the columns of a newspaper to be not the most proper for giving medical subjects, he will find in the *Medical Times and Gazette* of next Saturday, a statement of the grounds upon which my opinions were formed.

I am, Sir, your obedient,

St. Columb, April 19th, 1852. W. MOORMAN, Jun.

IV.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your readers will not envy the thoughts of the Mr. Moorman who gave evidence in the case of that unfortunate victim of trial by "his peers,"—Mr. Pascoe. If your report contains *all* the grounds from which a guilty intent was assumed, I can only say, that *I* deserve transportation for ten

years as much as Mr. Pascoe. I happen to have a patient suffering from amennorrhœa at the present time, who has been taking savine, together with aloes and the steel mixture, for three weeks past. I have little doubt there may be two or three hundred instances in the kingdom of the same kind.

For the sake of justice, Sir, pursue this matter in the proper quarter. To my own mind, being a stranger to the circumstances, except as you narrate them, and to the parties, the evidence on which Mr. Pascoe was condemned carries the strongest conviction that he was innocent. I hope the Profession may speak out and save the victim. I am, &c. M.D.

V.

[To the Editor of the Medical Times and Gazette.]

Sir,—I trust it is not necessary to appeal to any great names in order to remedy the injustice done to Mr. Pascoe, if your suggestions are correct, as appears most probable.

Mr. Moorman's remarks appear to me both unjustifiable and cruel. Permit me to mention, that I once knew a medical practitioner so completely ruined as ultimately to lead to his resorting to intemperance and suicide, although he had a large family, by the evidence of a physician, and, as a result of that evidence, the censure of the presiding judge, and loss of his action, and in fact of his entire practice. The action was for medicines and attendance in a case of secondary syphilis; the physician referred to swore that he believed in such, and indeed in all cases, that sarsaparilla was of no more use than so many chips of deal. I may add that this same physician, although he was very highly connected professionally, met a few years after with a case so puzzling, and in fact discreditably fatal, that he prudently retired from the Profession.

I am, &c. M.D.

VI.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have read with much surprise and no less pain your extracts from the newspaper account of the trial of Mr. Pascoe, and I agree most fully with the observations in your leader upon this most remarkable case. It appears to me extraordinary, that a judge should propose such questions as appear in this case to have been proposed, while questions of vital priority (if such an expression may be allowed) were passed over without the slightest attention. A medical practitioner, however competent to the ordinary duties of the profession, is questioned as to his opinion upon certain abstract points of casual occurrence, but still requiring an intimate knowledge of jurisprudence, and perhaps the greatest depth of thought, and the most careful and cautious reflection.

I shall not criticise the charge to the jury,—it would occupy more time than perhaps would be beneficially so employed. But it may be worth while to observe, that a person, confessedly ignorant of the common literature of his Profession, is called upon to state his opinions upon certain matters, and these crude notions submitted to the jury as dogmas upon which their verdict is to be based.

From the fact of Mr. Pascoe having examined the breasts of the patient, I think it probable that she informed him she was labouring under amenorrhœa; and, naturally enough, as was his duty, he looked to the breasts to assist him in diagnosing the cause. That the mammæ afforded no indications of pregnancy, may be inferred from his prescribing the compound mixture of iron; and we may further infer, that, this proving ineffectual, Mr. Pascoe resorted to savine, which he, like others, may be in the habit of prescribing in such cases.

That savine is regarded as an emmenagogue will appear by reference to Murray's "Materia Medica," where it is stated:—

"Savine is a stimulant, the operation of which has been supposed to be powerfully directed to the uterine system; so much so, that, according to the common opinion, it is capable of producing abortion; but this is doubtful. It appears to possess greater powers as an emmenagogue than any of the substances which have been mentioned, and is sometimes given with advantage in amenorrhœa."(a)

If the medical gentleman who bore so hardly upon his professional brother had consulted the Materia Medica of the College of Physicians of London, he would have found juniperus sabina included in the list, and that the "fresh and dried tops" are the parts specified for use. Had he consulted Murray, or, if he preferred the more recent authority, "Phillips' Translation of the Pharmacopœia of the Royal College of Physicians, London," he would have founded it stated, that the dose of the fresh leaves is, according to Murray, from a half to one drachm; to Phillips from ten grains to half a drachm.

It is to be greatly lamented that our courts of law are left to seek illumination from persons whom chance may throw in their way, and who have paid so little attention to those often delicate and intricate distinctions as to be wholly unqualified for such nice discriminations. Persons of known capability should be appointed to attend, and assist the judges upon occasions of such deep importance.

Much stress has been laid upon no initials being attached to the prescription. Mr. Pascoe, not being a physician, was not legally entitled to put his initials to a prescription; and suppressing the name of the patient might have been from motives of delicacy. No man with such intentions or motives as those attributed to Mr. Pascoe would have openly sent out his prescription, or delivered it to the patient, to be sent, in the ordinary way, to a chemist for preparation. That Mr. Pascoe has suffered a great wrong there can be no doubt: the mode of repairing it is probably by a memorial to the Secretary of State. Should such be adopted, I shall be ready to attach my humble name to the document.

I am, &c. Justitia.

[We must now terminate our correspondence upon this subject; and we do so the more readily since we have reason to entertain the most confident expectation that our exertions in this case have exhibited the entire failure of Mr. Moorman's evidence, and will insure a free pardon to Mr. Pascoe.—Ed. *Medical Times and Gazette.*]

(a) Murray's Materia Medica, pp. 281, 282.

STATISTICS OF THE ROYAL MATERNITY CHARITY.

[To the Editor of the Medical Times and Gazette.]

Sir,—I send you a summary of the cases that occurred in the Eastern District of the Royal Maternity Charity during the last year, similar to those which have on previous occasions been published in the *Medical Gazette*. As I have resigned my appointment in that charity, this is the last report that I shall have the opportunity of laying before the Profession. I am, Sir, &c.

Francis H. Ramsbotham, M.D.

7, Portman-square.

During the year 1851 there were delivered under the superintendence of Dr. Ramsbotham 1432 women; of which cases

1 was a triplet; the children were all females; the first presented with the head, the second with the knees, with this child the funis also prolapsed; the third with the breech. They were all fully as large as individual twins usually are, and were all living and healthy a month after their birth.

11 were twins,—1 in about every 130 cases. Of these, in 5 cases, both heads presented; in 1 both were breech or inferior extremities; and in 5 the presentations were head and breech, or inferior extremities. In 3 of these cases the children were both boys; in 5, both girls; and in 3, 1 boy and 1 girl.

Of the 1445 children—

758 were males,

687 were females.

1414 were presentations of some part of the head; of these, 5 were face presentations; 1 in every 289 births.

26 were breech presentations,—1 in about very 55½ births.

5 were transverse presentations,—1 in every 289 births. In all these cases the shoulder presented; all the women were delivered by the operation of "turning." In 1 case there was considerable hæmorrhage for four or five hours before delivery could be accomplished. The child was born living, and the woman did well. All the women recovered; but 3 out of the 5 children were born still.

In 3 cases the placenta was implanted completely over the os uteri; 1 in about every 477 cases. All these woman were delivered artificially. 1 was in the eighth month of pregnancy. She had suffered three or four attacks of hæmorrhage at different times, before labour set in; and, when the process was established, lost much blood suddenly. In a few days after delivery pneumonia supervened, and she had a very protracted recovery. Another was at the full period, and, though the flooding was very copious, she recovered well. The third was a case of great interest and rarity. The woman had had a large family, and, as I was told, had three or four times been severely affected with syphilis. For some weeks before labour she had suffered from violent pain, deep-seated, behind the right groin, and during that time had been the subject of several attacks of rather profuse hæmorrhage. She had been under the care of one of the district surgeons, and I did not see

her until a week before her delivery. She was then much emaciated, and had the appearance of a person who had lain for some time under low fever. The whole uterus was very tender; but low down on the right side, the pain on pressure was so acute as to preclude any very minute examination. There was no external swelling perceptible. A constant discharge of blood and sanies of a most offensive character was going on. Examination per vaginam discovered the os uteri sufficiently dilated to admit the extremities of two fingers, hot and exquisitely tender, and the placenta was detected entirely covering it. As there was no indication of uterine action, I did not think it prudent to attempt delivery then, but contented myself with watching her closely. The passage of the urine gave some pain; but defæcation was attended with more. The hæmorrhage ceased during my attendance, and the woman appeared somewhat better. After the lapse of a week, the midwife came to me one evening to say, that the placenta had just passed externally with considerable flooding, though there had been scarcely anything like uterine action. I saw her immediately, and found the placenta in a chamber-pot, most offensively putrid; so much so, indeed, that I was glad to separate it, by dividing the funis, and to send it from the room. There was also in the same vessel a fresh coagulum, that would have filled a quart measure. The os uteri was not entirely dilated, and was still very hot and tender; the breech was at the brim; there was a draining of blood then going on. The woman was evidently sinking, and it seemed to me better to deliver her than to allow her to die with the child in utero. I therefore brought down a foot. As the breech was passing the os uteri I felt a rent take place, most probably both in it and in the vagina, though the extraction called for very little effort. Immediately a quantity of fetid pus escaped,—certainly more than a pint. The child was very putrid, and the cranium was greatly distended with putrefactive gas. After the child was extracted, a large discharge of horribly-stinking pus took place, mixed with a considerable flow of blood. The poor creature died within an hour of delivery. An examination was not allowed; and I cannot, therefore, positively state the seat of the abscess. It appeared to me, however, that it had formed in the cellular substance on the right side of the pelvis, and that the os and cervix uteri had become inflamed and softened, in consequence of its proximity to the sac in which the pus was secreted.

Three were complicated with dangerous hæmorrhage before delivery, at full time, *not* the result of placental presentation,—one in about every 477 cases. In all the child was expelled naturally, and all were still. In all these cases the flooding ceased on the artificial rupture of the membranes.

In 12 cases, the placenta was retained within the uterus after the child's birth, either by atony or irregular contraction of the uterine fibres, or by morbid adhesion between the placental and uterine surfaces, requiring the introduction of the hand for the purpose of removal,—1 in about every 119·3 cases. One of these was after the expulsion of twins, each of which was much larger than single children usually are, both the placentæ being retained; another after the operation of craniotomy had been performed.

Three were complicated with dangerous hæmorrhage after the expulsion of the placenta,—1 in about every 477 cases. In one case, the discharge appeared to be produced by a woman putting a hot plate enveloped in flannel over the uterus, soon after the departure of the midwife, to allay the violence of the after-pains. The midwife had left the uterus well contracted, and the woman apparently safe. On being summoned back again, she found the uterus relaxed, and filled with coagula. The patient had a narrow escape from death. Another was a very unusual case. There had been hæmorrhage to an extent to give some alarm soon after the expulsion of the placenta; this was arrested by pressure and cold applications. The woman went on very well for a fortnight, had left her bed, and seemed recovering satisfactorily. On the evening of the fourteenth day after delivery, I was summoned hastily, in consequence of a fresh eruption of blood. I found that she had been subjected to a sudden and violent fright, which had produced much agitation. Copious flooding commenced almost immediately. When I arrived she was blanched and faint. Notwithstanding the fundus uteri could be felt through the abdominal parietes, just peeping up above the symphysis pubis; it did not seem as though the organ had relaxed much, if at all. Cold applications controlled the flow, and the woman gradually recovered. The other attack was six days after labour. There had been some hæmorrhage during the latter part of pregnancy, but none in the labour.

There was one case of puerperal convulsions at full time. The patient had six fits on the ninth day before labour came on. They ceased on the employment of the ordinary means, and recovery appeared to be perfectly established. She went through her labour also very well, without any recurrence; but the morning after her delivery two fresh fits came on. Quiet, cold to the head, and purgative medicine, relieved her. Headache continued for three or four days, but after that her convalescence continued uninterruptedly.

Three were delivered by craniotomy,—1 in about every 477 cases. In all these cases there was a contraction of the pelvic brim in the conjugate diameter. In two, it was the patients' second child; they were both face cases, and the women had both been delivered by craniotomy in their previous labours. The third woman also had a contracted pelvis in the conjugate diameter of the brim. She had been the subject of three or four lingering labours, and, in her last, was delivered by the long forceps. On this occasion, the district surgeon applied the long forceps, and used as much exertion as he deemed he was justified in doing, without avail. As the woman was in a state calling for delivery, and as the anterior lip of the os uteri was pinched between the head and the pubis, and much swollen, he thought it right to open the child's head, and terminate the labour at once. The patient recovered without a bad symptom.

Four were delivered by the forceps,—1 in every 358 cases. One of these was a first labour; the woman died on the eighth day after delivery, from peritonitis. One was a sixth child; the head had turned, with the face to the pubis. One was a twelfth child, and very large. One woman's pelvis was small throughout; she had been delivered twice before by instruments.

In one case, premature labour was induced between seven and eight months, in consequence of there being a distorted pelvis. This was in January. I had brought on labour prematurely for the same patient three or four times before; and I did it again last month (March). On the occasion in 1851, now under consideration, she took half-a-drachm of fresh ergot in infusion every six hours for nearly a week; slight uterine pains supervened after she had taken ten or twelve doses; and on the seventh day, when I examined, I found the os uteri dilated to the size of half-a-crown, and the membranes rather tense, head presenting. I ruptured the cyst, expulsive pains came on in about eighteen hours, and she was soon after delivered of a live child. The same occurred in March last, under the same treatment, only that she took the ergot rather longer, and active labour came on more speedily after the membranes were ruptured; whereas, in the year 1849, labour was induced by the ergot alone, the membranes rupturing spontaneously, as recorded at page 793 of the last volume of the *Medical Gazette*.

Maternal Deaths.

3 women out of the 1432 delivered, died within the puerpera l month—1 in about every 477 cases—1 nine days after delivery, from pneumonia (this was in January;) 1 in eight days, from peritonitis, after delivery by the forceps; 1 within an hour after delivery, under placental presentation, with an abscess in the pelvis, as more particularly detailed above.

1409 children were born living;

36 still,—1 in less than every 40 births.

Of the Still-born Children,

7 were premature; of these 3 were putrid, and 3 were breech presentations; 1 was a shoulder presentation; 1 woman had met with an accident a fortnight before.

13 were putrid, at full time, or nearly so.

2 were breech presentations at full time; they were both first children.

3 were delivered by craniotomy.

1 was delivered by the forceps.

1 was a second child of twins.

1 was after the woman had suffered a fright three days before her labour.

2 were transverse presentations at full time.

1 was under placental presentation,—the case of abscess in the pelvis,—the child putrid.

3 were after dangerous accidental hæmorrhage.

In 1 case the pelvis was distorted; but the child (a boy) passed without assistance. This woman had had 3 children before—2 boys, both dead; one girl, living. This may be accounted for, perhaps, by the fact, that the heads of male children are usually somewhat larger than those of female.

1 was at full time, not putrid, nor delivered by art.

ON THE UTERINE SOUND.

[To the Editor of the Medical Times and Gazette.]

SIR,—I regret that an accidental error should have occurred in one of my former letters, or that any misapprehension as to the meaning of a phrase should exist. I will, however, re-state the

facts, in the hope that this time they may be stated more clearly In October and December, 1851, Dr. Rigby published two papers, illustrated by cases, on dysmenorrhœa, wherein he divides this affection under two heads—mechanical and functional. Mechanical dysmenorrhœa is there considered to arise from a contracted or closed state of the os uteri, or canal of the cervix, in consequence of which the fluid is discharged with difficulty and much suffering, or altogether obstructed; and, to cure this affection, the contraction is recommended to be dilated by blades made of well-tempered steel, or slit open by a knife ingeniously contrived for the purpose. The same treatment is applied to the virgin as to the married female, and a case is given of this said mechanical obstruction occurring in a virgin female—Miss B., aged 36—wherein, on the examination, *per vaginam*, it is said, "the uterine sound passed rather more than 2½ inches." Now, could this be done when the os uteri, or canal of the cervix, was in a contracted or closed state? Unquestionably not. Nor could it be done in the healthy condition of the uterus,—for the internal orifice of the uterus, especially, is not of sufficient size to admit the uterine sound to pass, the bulb of which measures half an inch in circumference, or more than one-eighth of an inch in diameter. Nay, further, if the sound did pass more than 2½ inches—and we are bound to admit that it did, seeing that it is so stated—the os uteri or the canal of the cervix could not have been contracted, but must have been morbidly dilated, and consequently would afford no obstruction to the fluid when discharged. It hence follows, that this model case of mechanical dysmenorrhœa from obstruction is, from Dr. Rigby's own showing, not a case of obstruction, that the diagnosis was erroneous, and that the treatment employed was uncalled-for, and consequently improper.

It is unfortunate that Dr. Higgins is open to a somewhat similar charge; for in his paper on "The Uterine Sound," Feb. 28, p. 210, a case is given of "dysmenorrhœa from occlusion or stricture of the os internum uteri," wherein this is said to have been ascertained by the sound. Now, the bulb of the uterine sound is much too large to pass the os internum uteri, and hence could not afford any indication of a constriction of this orifice. Surely, then, these are cases of malpractice with the uterine sound, and not examples of any practical use to which it may be applied.

I am not surprised that Dr. Higgins should feel angry when he finds his various reasons for the employment of the uterine sound shown to be rather no reason at all, or cases of malpractice. And on reflection, he will perceive, that the task of pointing this out is an invidious one, and can only be done under an assumed name. "With a simple desire for truth," it is required that published statements should be freely examined, with the view of ascertaining whether they bear the interpretation put upon them; and this can be as well done under one name as under another. No doubt it is a wise decision to avoid discussing this question, for it would be inconvenient to those who use the uterine sound to have it shown that the employment of the instrument, except in rare cases, leads to no practical advantage, while it is liable to create much serious mischief. I am, &c. M. D. Londin.

CALCULUS OF THE BLADDER ON THE BANKS OF THE RHINE.

[To the Editor of the Medical Times and Gazette.]

Sir,—Having been requested by my much-respected friend, the late Dr. Prout, to ascertain whether calculus of the bladder was really, as reported, a disorder of rare occurrence on the banks of the Rhine, I addressed myself for information to the late Dr. Leydig, who deservedly ranked at the head of his profession in the city of Maing. His answer places the subject in so striking a point of view, that I am induced to send you a translation of it, thinking that, although the date is somewhat ancient, it may prove interesting to the readers of the *Medical Times and Gazette*.

I am, &c. Al. Henderson.

Curzon-street.

In your esteemed letter of the 16th instant, you have been pleased to submit to me the inquiry, whether calculus of the bladder was a complaint unusually common in this locality; and, if so, whether or not the cause of its occurrence was to be referred to the more or less free use of the wines of the country.

In answer to these questions, I beg to state, that, during the thirty-two years that I have been settled here, and have practised as consulting and operating surgeon in a circle of fifteen leagues and upwards, comprising the localities where the principal Rhine wines are grown, I have met with only five cases of vesical calculus, and none of them in patients belonging to the higher classes. The first was in a butcher, 65 years of age, at Bretsenheim; the second in a peasant lad, of 25, from Nackenheim; the third in a widow, 34 years of age, from Strasbourg; all of whom were successfully operated on and cured. The other cases which came under my notice were in a Turkish Jew, who stopped here on his travels, and in an old man of 70, neither of whom would submit to an operation, and who both were victims of the disorder. Besides these cases, I have never heard of any occurring in this district during the above-mentioned period, nor, as far as I am aware, has there been any operation for the stone by other practitioners; and my highly-respected teacher, the late Professor Weidmann, has often expressed to me his regret, that, during an extensive practice of twenty-five years in this town and neighbourhood, he never had an opportunity of performing the operation of lithotomy, and had met with only one case of urinary calculus, viz., in a child, whose parents would not consent to an operation.

The result, then, of my own experience, as well as that of my illustrious predecessor, is not in favour of the frequent occurrence of urinary calculus in this locality; but, on the contrary, tends to prove that the cause of the rarity of the disorder among us, and particularly in the higher classes, is to be found in the goodness, and purity, and peculiar qualities of the wines with which the country abounds, and which have long had, and still deservedly maintain, the repute of being an excellent preservative against this disease.

I beg to renew the assurance of my highest esteem, and have the honour to be, your most obedient servant,

Dr. Leydig,
Privy Counsellor and Surgeon-in-Chief to H.R.H. the Grand Duke of Hesse-Darmstadt, etc. etc.

Maing, May 20, 1826.

THE LARGE PAYMENTS UNDER THE PROPOSED NEW CHARTER OF THE COLLEGE OF PHYSICIANS OF LONDON.

[To the Editor of the Medical Times and Gazette.]

Sir,—Will you permit me to call the attention of my brother physicians in England and Wales to the heavy taxation the Royal College of Physicians proposes to inflict upon us? It appears from a draft copy I have had the opportunity of examining, that the physicians in the provinces will have to pay on admission to this virtually new College, the sum of 15*l.* 15s., exclusive of stamp-duty. They are then, however, only "members;" if they proceed to the higher rank of "fellows" they will probably have to pay an additional sum to the College funds (not specified in the Charter), and an additional tax to Government. This may be taken to be the same as at present, viz., 30*l.* to the College, 25*l.* tax.

	£	s.	d.
Member's fee	15	15	0
Stamp-tax on parchment	15	0	0
Fellow's fee	30	0	0
Stamp-tax on parchment	25	0	0
Total payments	£85	15	0

Or 40*l.* to the Government and 45*l.* to the College. These are heavy sums, and deserve the attention of English physicians. So long as the College was content to remain a mere London club, we in the country had little reason to interfere with it, but seeking to control the whole body of English physicians, and to obtain the legal privilege of granting the degree of "Doctor of Medicine," it is really necessary to watch its proceedings, and see whether the steps it proposes to take comport with the dignity and pecuniary and professional interests of the general body of physicians.

As regards the tax it would inflict, I think there can be only one opinion; it is undoubtedly gratuitous, and almost as undoubtedly unjust. The greater number of us have already paid a heavy stamp-duty upon our diplomas; we are also taxed to the Income-tax, and to the assessed taxes for our servants, horses, and carriages, used solely, in the greater majority of instances, for professional purposes; so that, as regards taxation, we are by no means a privileged body; and, if the Government had directly demanded this additional sum of 15*l.* (or 45*l.*, as the case may be), it would have been considered as simply a case of extortion. Why the College should deliberately more than meet the Government in so unfair a demand, requires some explanation; and until an explanation be given, the grant of this Charter should be resisted by every one who means to stand by his Profession.

The payments to the College have not such a grievous aspect; but still it may not be unprofitable to inquire, why so large a sum is to be paid by the postulants for admission. The College, it is reported, is heavily burdened with debt. If this be the fact, a

balance-sheet of liabilities and assets should be laid before the general body of physicians, so that we may be made acquainted with the actual condition of the College funds. It would be well, also, if there were some statement made public as to the advantages which would accrue to society and to physicians in general by this new incorporation, so that the pecuniary demands may be, in some degree at least, defended on the ground of utility. The College has not only altogether neglected to explain these matters, but has not, so far as I am aware, made even the draft of the new Charter public, or asked the opinion of their brethren as to the new powers and constitution they propose to confer upon the College. This conduct is by no means in accordance with the English method of condnctiog public business, and cannot fail to excite dissatisfaction and distrust. I am, Sir,

MEDICUS ANGLICANUS.

COLLEGE OF SURGEONS' FELLOWSHIP.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am one of those ill-used men, a Provincial Fellow of the Royal College of Surgeons of England by examination. Had I been rejected I should have been ruined, and my diploma is now valueless. After having gained it in the legitimate way, (the only way I was then solemnly assured by the Council in which it could be acquired), I am informed, that all men with a diploma as member of so many years' standing, commencing from such a date, can be elected without examination at all, upon the payment of ten guineas, with the recommendation of six Fellows. Sir, London surgeons are more free than we in the provinces. What "Fellow" in a small town, or in a rural district, would incur the odium of refusing to sign this recommendation for the thickest-headed druggist, who, since scraping through the College with the aid of a grinder, had done nothing but play nurse to old women, and vend scented soap and tooth-brushes for fifteen or twenty years? Not I for one. The College shall not cast the odium upon my shoulders. To many of us the idea occurred of returning the useless parchment, called the diploma, to the source whence it came; certainly I cannot imagine any one, however low, too unworthy of such a degree, the course of which since its foundation has been characterized only by shirking and by sharking.

As to the ten pounds, that may be raised by a Fellowship Assurance office, the Directors of which should be composed of those, who, after such solemn promises, have had the assurance to break faith in so gross a manner with all who have submitted to the ordeal of an examination. We were once called the self-degraded; perhaps we shonld better merit the term of self-stultified. I presume no Fellow by examination will attend the farce of election of members of the Council, or will disgrace himself by attending the dinner. I am, &c.

A PROVINCIAL FELLOW.

CANNABIS INDICA IN TRAUMATIC TETANUS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you allow me to record in the pages of your Journal the history of a well-established case of traumatic tetanus successfully treated by Indian hemp. As you are aware, Dr. O'Shaughnessy used this drug with considerable success in combating this fatal disease, and subsequently Professor Miller published a case in which recovery followed its administration. Every additional testimony to the power of the cannabis indica, over the abnormal condition of the nervous system that appears to constitute the essence of this disease, should, I think, be placed before the medical world with as little delay as possible.

Samuel Chappel, aged 7 years, a healthy, well-grown child, of sanguine temperament, the son of respectable poor people, living in a healthy situation, was struck by a stone on the 16th of last October, which produced a wound about half an inch long, near to the outer side of the right eye. When the wound was quite healed, eight days after the accident, the mother noticed a strange expression of his face, and that he closed the right eye with difficulty. These symptoms increasing, her apprehensions were excited, and the child was placed under the care of my partner (Mr. Cribb) and myself. At this time, Nov. 1, the right eye was widely open, and could not be closed by his strongest effort; the pupils were dilated; there was the mark of a recent incised wonnd on the outer side of the right eye; the mouth was opened with difficulty, and less widely upon the right than the left side; upon coughing or sneezing, the right side of the face scarcely moved; bowels constipated; general health good. Aperients were ordered, and leeches were applied between the wound and the trunk of the facial nerve; poppy fomentations to the side of the face.

3rd.—Much worse; right eye fixedly open, and jaws firmly closed; great difficulty in swallowiog; a few drops passed between the teeth, the attempt producing spasm of the muscles engaged in deglutition; occasional attacks of rigidity of the whole of the frame; some tendency to opisthotonos. His teeth are small (milk teeth) and do not overlap, consequently fluids can be got into the mouth with tolerable facility. Ordered the following: Grain doses of the resinous extract of Indian hemp every three hours, an enema of compound decoction of aloes, tincture of assafœtida, and water; a paste composed of extract of belladonna, blister plaster, and antimony, to be rubbed in over the whole of the spinal column. Strong beef-tea and milk arrow-root. From this time up to Nov. 7 he got daily worse: the attendants experience so much difficulty in giving medicine and food, from the spasms consequent upon every attempt to swallow, that they could not be induced to carry ont our directions, and they were the less disposed to persevere, from a conviction that the boy must die, and an unwillingness to disturb him from the drowsy state induced by the little medicine they had forced down.

8th.—Jaws firmly closed; right eye open and lower lid everted; conjunctiva inflamed; awakes with a cry of horror and rigidity of the whole frame; well-marked opisthotonos; pulse feeble; much emaciated. From this date, by repeated visits, arrangements were made for giving medicine and food regularly, and he took for several days consecutively from a grain to a grain and a half of the extract of Indian hemp every three or four hours, beef-tea, tea with egg, etc. The food was generally given immediately after a dose, as he was then able to swallow better. From the 10th he began to improve, although very gradually—recovering by degrees, first the power of swallowing, then of separating the jaws, and, lastly, of closing the eye. The general spasms became less frequent. By the end of the month he was quite well, and continues so up to the present time.

Chappel took in nine days 64 grains of the extract, in all 162 grains between the 3rd of November and the 3rd of December. The only unpleasant result occurred about November 22; when nearly convalescent, and still taking the extract five or six times a day, it appeared to produce considerable pyrexia and conjunctivitis; these symptoms quickly yielded however to a brisk purgative and greatly diminished doses of the hemp. I believe the preparation to be recent and very good; lately I found such marked effects follow grain doses that were given to two adults, that I was unwilling to continue its use. I am, &c.,

Bishop Stortford. CHARLES F. HODSON, M.R.C.S.

MEDICAL SOCIETY OF LONDON.

[To the Editor of the Medical Times and Gazette.]

SIR,—I will thank you to correct an error in a report of some few observations which I made at the Medical Society of London, at the discussion which followed the reading of my contribution on "Fatty Degeneration."

I am represented to have stated that, "in real apoplexy, bleeding is not practised, as was formerly the case."

I only ventured to say that, as apoplexy may be traced very often to a process of degeneration, resulting from atrophy, our practice, as to blood-letting, should be much modified in not a few cases of this affection; often, indeed, no blood should be taken. But still cases do happen, and that not rarely, in which it would be extremely bad practice not to use the lancet. I am, &c.

Westminster Hospital. W. F. BARLOW.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

J. HODGSON, Esq., F.R.S., President, in the Chair.

A FEW REMARKS ON THE SURGICAL OPERATIONS USUALLY ADOPTED FOR RETENTION OF URINE,

TOGETHER WITH AN ABSTRACT OF CASES, IN WHICH THE BLADDER WAS PUNCTURED THROUGH THE RECTUM, FOR THE PURPOSE EITHER OF RELIEVING DISTENSION, OR OF FACILITATING THE CURE OF PERMANENT STRICTURE.

By EDWARD COCK, Esq.

The author first dwells upon the difficulties which surround the question as to what course should be pursued in those cases where

an old chronic indurated stricture, recently closed by inflammation and congestion, defies all attempts to pass a catheter, and upon the failure which frequently attends the attempts of the surgeon to relieve such cases by the introduction of sounds, catheters, or bougies. He points out the three modes to which recourse may be had, when the urgency of the symptoms renders some decided interference necessary. First, that of forced catheterism; secondly, that of opening the urethra in the perinæum behind the stricture; thirdly, that of puncture of the bladder. There is nothing new in either of these measures for relieving retention. They may each possess certain advantages, and the circumstances of the case, and the condition in which we may be placed, may incline us to the adoption of either the one or the other. They have all their drawbacks; but, on the whole, the author is disposed to believe that the bladder may be reached with the smallest amount of pain, with the least risk of present or future danger, and with the greatest prospect of ulterior good, by puncture through the rectum. The first of these operations the author regards as in reality a mode of puncturing the bladder with a blunt instrument, tunnelling through the perinæum under cover of the urethra; and he believes that the stricture is, in the majority of such cases, neither forced nor crushed, but that a new passage is made outside the urethra, which may either re-enter it, or continue its course through the prostate into the bladder. The urgent symptoms may be thus relieved, but the after condition of the patient is not bettered, and it may be rendered even worse. The second operation, that of section of the perinæum, the author thinks, is, when dexterously and successfully performed, preferable to forcible catheterism. The urine may be allowed to flow by the new channel, until the urethra has had time to recover itself from the injuries it may have sustained by previous manipulation, or from the irritation caused by the continual pressure of the contents of the bladder. But, unfortunately, the difficulties are often so great, in long-standing disease of the perinæum, that the urethra cannot be reached, and great mischief, or even death, may result from the protracted operation. The author describes the proposed modification of this practice, called "cure of stricture by division," of which the principle consists in uniting the upper and lower permeable portions of the urethra by the division of the intermediate impermeable portion, and thus restoring the integrity of the canal. This, however, he thinks, is very rarely carried out; and that very often death is caused unmistakably from the injuries sustained during the operation. So convinced is the author, by experience and observation, of the difficulty which frequently attends the operation of opening the urethra behind the stricture, where the landmarks which should guide us are obliterated, that he has of late years abandoned the operation of incising the perinæum with a fixed determination to reach the bladder. In those cases where retention and extravasation render it necessary that an outlet should be afforded to the contents of the bladder through the perinæum, he limits himself to making a free incision down to the region where the urethra may be supposed to be situated; and if he cannot then gently introduce a catheter through the wound into the bladder, he does not proceed any further; and he has generally found that the urine has speedily made its way through the wound. With regard to the third mode of relieving the bladder, by puncture, the author brings forward cases to show that puncture by the rectum is safe and simple. Forty cases of operation by the rectum are related. In all of these, the operation was entirely successful, so far as the relief and the absence of any ill consequences from it were concerned. Seven deaths occurred from various causes connected with the previous sufferings of the patients, such as diseased kidneys, inflamed bladder, etc. In many cases, the author believes the operation to have materially tended to the restoration of the patient, with a less amount of suffering, and, at the same time, more speedily and effectually, than could have been effected in any other way.

Mr. Solly thought the Society were much indebted to Mr. Cock, for calling their attention to the value of the operation described by him in his paper. He had heard Mr. Cock speak of it several years ago, and he had since repeatedly performed it with success, but in cases which had been selected for the purpose, and which, consequently, did not bear so great a value in estimating its importance. He (Mr. Solly) considered this operation to be one of the least dangerous that can be performed in cases of retention of urine from stricture. There are cases, of course, in which it is advisable to cut down upon the urethra, such as those where the stricture is of traumatic origin, but in cases where the canal has been much damaged, and where false passages exist, he thought this operation was one of the least dangerous in surgery.

Mr. Arnott, though not able to speak of the operation of puncture of the bladder through the rectum in the same unqualified terms of approbation as the author of the paper and Mr. Solly had done, was yet able to add his testimony generally in its favour from a personal experience of five cases in which he had performed it; and he thought the thanks of the Society were due to Mr. Cock for having brought the present collection of cases before it. Mr. Arnott had only resorted to the operation in cases of retention of urine supervening on permanent stricture where other means of relief had failed; but, having witnessed incidentally its advantages in facilitating the subsequent treatment of the stricture, which had rendered the operation necessary, he was prepared to receive favourably the suggestion to resort to it occasionally in the treatment of stricture. But before further adverting to it, he might be allowed to observe, that he thought Mr. Cock had been too severe in the language he had used with regard to the operation of what was called forcing the stricture, and also in regard to the other operation of opening the urethra behind the stricture. Both these proceedings, properly performed in suitable cases, were justifiable and safe. The operation of forcing a stricture was not so severe a proceeding as puncture of the bladder from the rectum, and it had some advantages; and if it were his own misfortune to have retention of urine from stricture, he would, in the hands of a surgeon who knew his business, prefer that the forcing the stricture should be tried upon him, before submitting to having an opening made in the urethra behind the stricture, or the bladder punctured from the rectum. What he meant in speaking of the operation being properly performed was this, that, if upon trying to urge the catheter through the stricture, the urethra itself should give way and be perforated, then that the proceeding should be immediately abandoned. So also with regard to the opening the urethra behind the stricture; the best mode of doing this was not the usual one of cutting from the surface or skin inwards, but by putting the fore-finger of the left hand into the anus so as to depress it, then to introduce the point of a bistoury only slightly curved just in front of the anus, and carry it directly inwards so as to strike the dilated membranous part of the urethra, and then hooking the instrument outwards to divide all the superjacent parts. Mr. Arnott had first seen this mode of operation employed by Sir Charles Bell, twenty years ago, and he had frequently performed it since with success. If you missed the urethra, you could then resort to puncture of the bladder. With reference to the last operation, which was one which had been employed at the Middlesex Hospital, he had not found it so entirely destitute of disadvantages as Mr. Cock. Of the five cases in which he had employed it, one patient died; and on examination an abscess was found between the bladder and rectum in the track of the canula. Effusion of urine in this situation was a danger to be dreaded, and he had expected that it would have occurred in some of Mr. Cock's cases; and, gratified as he was by hearing the short abstracts of some of them read, he should like to look over the details of the whole, before he could satisfy himself that the danger was not real. Perhaps he should best explain his views with respect to the employment of these different operations, by relating a case in which he had performed all three on one patient within a quarter of an hour. In 1844, he had been called one morning to an officer of engineers who had retention of urine from stricture, and who had had a similar attack some years previously. The patient was 6 feet 6 inches in height, of large frame, and partially palsied on one side, rendering him very cumbrous to move. An attempt was made, but without success, to introduce an instrument into the bladder. Large and repeated doses of laudanum, at short intervals, by the mouth and by the rectum, were exhibited, and at the end of some hours a fresh attempt was made, without success, to pass a catheter; but, as a small quantity of water had dribbled away, the patient was now purged, cupped on the perinæum, etc. On the following day, the quantity of urine passed was not considerable, yet the relief was such as to lead Mr. Arnott to hope that the difficulty in the case had been got over. Early the next morning, however, he was again summoned to the patient, and found that he had passed no water since the preceding afternoon, was greatly distressed, the distended bladder reaching half way up to the umbilicus. Deeming that the case did not now admit of delay in obtaining relief, he first endeavoured to force the stricture, but, in the attempt, the urethra was perforated, and the catheter was at once laid aside. Mr. Arnott then explained to the patient's brother, a physician, that he would try to open the urethra behind the stricture, in which endeavour he had generally, in cases of this kind, succeeded; but, in the present instance, he did not feel so confident, as there had not been much previous suffering from the stricture, or push upon the parts, so that possibly the urethra posterior to the stricture was not dilated. If he failed, he should then puncture the bladder by the rectum. The attempt to lay open the membranous part of the urethra was made in the way already described, but the urethra was not struck. The bladder was then immediately punctured through the rectum. Mr. Arnott saw the patient twice during the day, when the urine was

flowing freely through the canula. But next day he was called to the patient, and learned that in the previous afternoon the canula had got displaced,—it was, in fact, out of the bladder,—so that no urine had since passed either way. The bladder was now full, and, after a short but unsuccessful attempt to pass a catheter by the urethra, the bladder was again punctured per rectum. The canula was kept in for sixteen days, when an instrument was got through the urethra into the bladder. The case did well, and the patient is still living. In one instance it appears that Mr. Cock had failed to reach the bladder in the attempt to puncture it through the rectum; but failure to strike the bladder was not confined to puncture in this situation. Mr. Arnott had twice witnessed, in the hands of very able surgeons, the bladder missed in the attempt to puncture it above the pubes; in one of these cases, the trocar was re-introduced, and with success. He might add, that both cases recovered.

Mr. Coulson said, that the great point connected with this operation was, that it might be done with ease and safety; he had performed it twice within a short time on the same patient. He thought that the great reason why it was not generally adopted was, that it does not touch the cause of the retention. Liston condemned it in strong language in his work on "Operative Surgery." Mr. Cock, in one of his cases, passed a small instrument into the bladder before he performed the operation; now, there was no reason why he should not have retained that instrument, and thus have avoided the necessity for the other proceeding. He should not himself be inclined to practise the puncturing of the bladder by the rectum in cases of extravasation and urinary abscess; free incisions would be quite sufficient to afford an exit for both the urine and the matter. In the class of cases where there exists an obstinate stricture, and there is no possibility of passing an instrument, life is at stake, and there is no alternative. In some of Mr. Cock's cases the urethra became pervious after the operation. He should not expect this to occur in all cases. In a case in which the canula had slipped out, and the hole made by the trocar could not be found, the permeability of the canal had not been restored, and it became necessary to divide the stricture with the lancetted stilette. If he could get a small instrument into the bladder during the existence of retention, he (Mr. Coulson) should prefer Syme's operation, or, if there were not any great urgency, he should practise the old operation described by South, in his edition of "Chelius' Surgery;" he should pass a grooved staff down to the stricture, and then cut down upon it through the perinæum beyond the stricture, then pass a strong straight director, deeply grooved, in the median line between the urethra and the rectum; next run a straight bistoury some distance in its groove, and afterwards cut outwards and upwards towards the staff in the canal.

Mr. Solly remarked that Mr. Liston, before his decease, recanted his error, as regarded this operation, as he was present when Mr. Liston performed it on a solicitor, in Mark-lane, about seven months before he died.

Mr. Campbell de Morgan observed, that he had not read all the cases in the paper, but they all supported the same views, and showed that the operation did not remove the cause of the retention, as Mr. Coulson had remarked: but, in all operations performed on that account, the urine, after a time, passes more or less by the urethra, just as in the cases lately before the Society of stricture of the colon, where, some time after an operation had been performed, the fæces began to be discharged by their proper outlet, the anus, so that, after all, this operation of puncturing the bladder by the rectum is, in some degree, a cure for the cause of the retention.

Mr. Curling had listened with a good deal of attention to the cases in the paper which had been read to the Society, and, so far as he could judge from the brief details given, he had no objection to make to the puncture of the bladder in the instances cited. In the second case, it did not seem quite clear whether the abscess in the perinæum existed at the time of the operation, or had formed afterwards; but he did not believe that so excellent and experienced a surgeon as Mr. Cock would venture to puncture the bladder by the rectum in a case of retention of urine with perinæal abscess,—he would relieve the patient by a free opening at the part. Mr. Curling agreed with the author of the paper in the opinion, that the operation was more free from risk than was generally supposed, and in giving it the preference over forced catheterism. He was quite sure, that Mr. Cock, in treating of the latter proceeding, did not object to the perforation of a stricture by the skilful use of the catheter, but to the violence inflicted when the instrument was driven out of the passage, the course of which in its progress to the bladder had been so graphically described in the paper. Still, he was surprised to find that Mr. Cock had had occasion to puncture the bladder in so many instances. At the hospital of which he was surgeon (the London), cases of retention of urine were of very common occurrence among the dissolute population in the neighbourhood; and no less than 146 cases had been admitted in the past year. Yet this operation was very rarely performed, and he did not believe that the bladder had been punctured a dozen times during the past twelve years. He attributed this to the remarkable success attending the general treatment without instruments, by means well known to the Fellows of the Society. After the retention had been relieved in this way, and the local irritation had subsided, the cure of the stricture could then be conducted with as much advantage, as after the bladder had been punctured by the rectum. In the very few cases in which he had found it necessary to operate, he had punctured the bladder above the pubes, which, he believed, was as simple and as free from danger as the puncture by the rectum.

Mr. Gay said, from the experience he had had of the practice of puncturing the bladder from the rectum, he could speak of it in the highest terms, but only in a certain class of cases, viz., those in which spasm and inflammation suddenly supervened on old stricture, and retention with all its evils followed; of this class of cases, he (Mr. Gay) had not been able to detect many among those which had been read in connexion with Mr. Cock's observations on this subject. It was now six years since he (Mr. Gay) was called to see an old gentleman labouring under the severest symptoms, arising from retention of urine. He had suffered for many years under stricture, and the day before, after drinking hard, and being exposed to cold, the retention commenced. Many futile attempts had been made to pass a catheter into the bladder, and the urethra had thereby become severely lacerated. Hot baths, opium, leeches, &c., were had recourse to, and it was not until the symptoms of constitutional irritation had reached a fearful height that his assistance was called for. Under these circumstances, he thought it unwise to interfere further with the urethra in any part of its course; and, notwithstanding the bad odour into which the operation of paracentesis had fallen, he determined, but not without considerable anxiety as to the result of the procedure, to relieve the bladder by this method. His object was to put a stop to the fearful effects of an over-distended bladder, as well on the stricture as on the system at large, and thus to allow a sufficient time for that palliative treatment which almost always succeeds in these cases, and that within a moderately short period of time, if judiciously carried out. Leeches were again applied with fomentations, and opium administered internally, and, in twenty-four hours, the disease had so far subsided, that the patient passed his urine, and nothing more was heard of the puncture through the rectum. Mr. Gay thought that the state of the urethra in such cases is of all others most unsuitable to catheterism; and, from his experience in the case he had just narrated, and others which he has had since under his care, he should not hesitate to recommend the bladder to be punctured at any time to relieve the pain and general distress which arise from even temporary over-distension. Mr. Gay had adopted this treatment, in four or five other cases; and, so assured is he of the comparative impunity with which the bladder might in this manner be evacuated, that on one occasion he drew off a patient's urine by this method on three successive days, and no ill results whatever followed. With regard to another class of cases in which Mr. Cock has been in the habit of puncturing the bladder, viz., those of chronic permeable stricture, Mr. Gay had had no experience, nor could he see its utility. It appeared to him that the consequence of this practice was to add to an old stricture the undesirable complication of a fistulous passage behind it, and one which could not advance the cure of the original disease. He thought that in these cases judicious catheterism might accomplish all that could be expected. Mr. Gay felt that, on so important and interesting a subject, every surgeon who had had any experience should communicate it for the purpose of arriving at some really practicable conclusion; and it was this consideration that had led him to make these remarks.

Mr. Hodgson observed, that his own experience did not lead him to regard this operation as so simple and unimportant as it would appear to be from the discussion. There was the danger of wounding the vesiculæ seminales, which had not unfrequently happened, and in one case the inflammation had extended to the testicle, which suppurated. Again, the canula may slip out, and the opening close. There is great difficulty in keeping the opening patent long enough for the passive condition of the urethra to be of service in the restoration of the canal. The practice of passing a catheter or sound through the urethra, not forcibly, but by slow, steady, and long-continued pressure, is generally ultimately successful. This plan, he thought, would in most cases be found preferable to puncturing the bladder per rectum.

Mr. Prescott Hewett intended, in the few remarks which he had to make on the interesting subject before the Society, to confine himself altogether to the question of operating for retention of urine from stricture. He would at once say, that the opinion which he had formed was, that few, very few cases indeed, of reten-

tion of urine from stricture imperatively demanded an operation; and he was surprised to find that so many cases of this class had required an operation in one hospital alone during the last few years. Mr. Curling had stated, that in the London Hospital, operations for retention of urine had of late years been of very rare occurrence; but he (Mr. P. Hewett) would go a step further, and say confidently, that for the eighteen years during which he had been at St. George's Hospital, not a single instance had occurred in which it was found necessary to resort to any operation for the relief of retention of urine from stricture; and yet among the large number of cases of this kind yearly admitted into that hospital were some of a most severe and urgent character. As a matter of course, he had been obliged to operate upon cases of extravasation from rupture of the urethra with retention, which had been brought into the hospital in that condition, but this was altogether a different state of things, and one in which the treatment admitted of no doubt. For many years past, at St. George's, long antecedent to his (Mr. P. Hewett's) going there, cases of retention of urine from stricture have been treated, when catheterism failed, with opium and the warm bath, and for the last eighteen years, to his own knowledge, as already stated, and for some years more, no single instance has arisen where an operation has been required. On one occasion, and on one alone, had Mr. P. Hewett seen even anything like an approach towards such an operation. In this case, the patient, a man of intemperate habits, had been admitted into St. George's with retention of urine from stricture, and some false passages which had occurred during the repeated attempts at passing a catheter into the bladder. Another attempt to get an instrument into the bladder was cautiously made by the house-surgeon, but as this failed a warm-bath was ordered, and some laudanum given by the mouth, and under this treatment the patient soon became easier, and then passed a small quantity of water; shortly afterwards, however, complete retention recurred, and as no relief appeared to be derived from the treatment, the surgeon of the week was sent for, and another attempt to pass an instrument was again made, which also proved fruitless. Under these circumstances, as the bladder was getting largely distended, a question arose as to the propriety of tapping this viscus through the rectum, but as the patient, notwithstanding the great distention of the bladder, did not appear to be suffering over-much, it was ultimately decided that another trial should be made with a full dose of laudanum, two drachms of which were immediately given by the rectum, and within an hour afterwards the patient began once more to pass his water, and gradually emptied the bladder. Let opium be freely given, and, from what he had witnessed, he had no hesitation in stating, that an operation in such cases would be very, very rarely indeed required. In conclusion, Mr. P. Hewett stated, that he had never seen any ill effects arise in these cases from the free administration of opium, notwithstanding that he had in some instances given drachm doses every hour for three and four hours consecutively.

Mr. Charles Hawkins, in agreeing with what had fallen from Mr. Hewett, thought that there ought to be further discussion on the very interesting paper, considering not only its great importance, but the professional standing of its author. He was not satisfied that it should go forth to the Profession that this Society took so very favourable a view of the operation recommended for retention of urine by Mr. Cock as might appear from what had fallen from the previous speakers; for he himself was not satisfied that strictures generally required this operation. He had never heard a paper read in that room which astonished him more, or took him more by surprise than that in which the author related forty cases of "puncturing the bladder" which had occurred in his own practice or in those of his colleagues. Now he (Mr. Hawkins) had known St. George's Hospital longer even than Mr. Hewett—for above twenty years—and he had never known the operation performed there, and he could not learn that it had been found necessary to have recourse to it for nearly thirty years. He knew that those in the most extensive practice at this end of the town had found it necessary to have recourse to it only about half a dozen times in a period of forty years. Therefore it was very astonishing that so many cases could be got together from one hospital, or in the practice of those connected with it; and, indeed, till Mr. Curling spoke, he fancied it must be an operation peculiar to the other end of London; but it appeared that the London Hospital had not produced anything like the number of cases, though peculiarly well placed for bad cases of stricture. He was surprised to hear Mr. Solly talk of the advantage of this operation in cases of spasm. Now, it appeared to him, that those were not the cases for which Mr. Cock recommended the operation, but in those old cases of permanent stricture, where, from constant attacks of retention, and its consequences, the kidneys and bladder were becoming diseased, and under which the patient was likely to sink. In these cases of all the operations—when an operation was required—he believed, that recommended by the author of the paper to be the best. But he thought, in these days, when so many new ways of curing stricture of the urethra were put before the Profession, this Society should be especially careful lest any plan received its sanction without due consideration. He had taken the liberty to address the Society, in the hope of eliciting further information from older Fellows of the Society, and those better able to give it than himself. It was not that he did not think that when an operation for the relief of retention of urine became necessary, that that recommended by Mr. Cock was perhaps the one attended with least difficulty, and followed by fewer bad consequences than any other, but of the results he could say nothing from his own experience. He could call to mind but one case in which the bladder was punctured for retention of the urine that had come under his own care. In that case the operation was performed above the pubes with success, but he had been in the habit of passing an instrument for that patient since without difficulty. Of course he did not allude to cases in which operations had been performed for the cure of stricture where the stricture was permanent, (mostly from accident,) and performed not for the immediate relief of retention of urine. He had assisted at the operation in about half a dozen such cases, where cutting into the urethra through the perinæum was the one performed. He could not conclude without stating his surprise at the large amount of what Mr. Cock called bad surgery related in his paper, which he certainly did not so commonly meet with.

Mr. Curling rose to explain, that, in the cases in which the bladder had been punctured at the London Hospital, he included cases of retention of urine from enlargement of the prostate gland, which had been injured by instruments, and attended with hæmorrhage into the bladder. He would also mention a remedy for retention from stricture, which was not applicable to persons of debauched habits and broken-down constitutions, but succeeded remarkably in robust sailors and others,—he alluded to the administration of croton-oil. As soon as the remedy begins to act on the bowels, the patient is able to pass water.

Mr. Solly explained, that he recommended the operation in cases of permanent stricture, with enlarged prostate, or where great injury had been committed on the urethra. He supposed, from the remarks of the previous speakers, that more bad cases of stricture were admitted into the hospitals at the east than at the west end of the town.

Mr. N. Ward contended, that the operation was admissible in cases of retention with great distension of the bladder, even if it were done simply for the relief of the intense agony and suffering attendant on that complaint, and for the prevention of paralysis of the organ, on account of its simplicity and safety, as shown by the experience of several hospital surgeons.

Mr. Charles Hawkins expressed his surprise that Mr. Cock should have met with so many cases of stricture requiring the performance of such an operation, when so many surgeons longer in practice than himself had not done it once.

Mr. N. Ward had understood that Mr. Charles Hawkins was opposed to the operation altogether in the cases alluded to.

Dr. J. A. Wilson remarked, that, if he understood the debate correctly, this operation is sometimes followed by a fistula, and yet it had been described as simple and safe. He would leave that question for surgeons to settle. How could an operation be either simple or safe if it had such a result?

Mr. Holt remarked, that he entirely concurred in the observations made both by Mr. Curling and Mr. Hewett, and expressed his surprise at the large number of cases in which Mr. Cock had found it necessary to have recourse to an operation for the relief of retention of urine. He had been engaged for the last ten years in endeavouring to procure cases of stricture of the worst possible description, believing every case may be relieved without operation; and, although a large number of cases of retention of urine had come under his notice, yet he had only had recourse to operative procedure in one instance,—the operation consisting in opening the membranous portion of the urethra, which formed an elastic tumour behind the stricture, easily detected, and easily punctured. If the ordinary palliative treatment were had recourse to, and, the first effort failing, no further attempts to pass a catheter were indulged in, in almost every instance the urine would, in a few hours, escape, and in sufficient quantities to obviate all the urgencies of retention, and, in a few days, (the parts in the intermediate time having become tranquil,) a catheter could, in almost every instance, be passed. Were he called upon to perform any operation, he should have no hesitation in preferring, from its simplicity, facility, and immediate relief, that advocated by Mr. Cock. He considered the operation of opening the urethra behind the stricture a most hazardous proceeding, and one which ought only

to be had recourse to in cases where the membranous portion of urethra could be distinctly felt distended by urine. As a proof of this assertion, he might mention a case in which this operation had been attempted by one of the ablest surgeons of the day, a gentleman of vast experience, and who is one of the heads of the Profession, but the patient, from continued disease, died the same evening, and the *post-mortem* examination revealed the urethra completely transfixed, the knife having passed between the bladder and the symphysis pubis. Respecting the operation of forced catheterism, he felt quite assured Mr. Arnott would not sanction that operation in the common acceptation of the term, or, as is recommended by some surgeons, that a catheter *vi et armis* should be forced into the bladder irrespective of the intervening structures; such a proceeding could only be attended with danger, and probably cause the death of the patient. In conclusion, he felt assured that, by patience and proper medical treatment, the cases in which it might be necessary to puncture the bladder through the rectum would be very few in number.

Mr. Arnott, in reference to what had fallen from Mr. Holt, thought he had guarded himself against the supposition of being favourable to the operation of forcing a catheter into the bladder. He had stated, that he thought the attempt to force the stricture a proper proceeding in certain cases; and what he meant he would again state was this: that, with a short silver catheter, gentle but steady pressure should be made on the stricture,—if it gave way, good; but if the urethra yielded, and the surgeon at once knew this by the sensation communicated to the finger, and by the bleeding, then the catheter should be at once laid aside, and the attempt abandoned. Mr. Arnott coincided in the statement, that the opening of the urethra behind the stricture in the way in which it was usually performed, by cutting from the skin inwards, was a difficult, tedious, and uncertain operation. He had experienced the difficulties himself, and he had witnessed the same with surgeons of acknowledged eminence. He had also witnessed the occurrence described by Mr. Holt, of the bladder being opened at the anterior part of its neck. The other mode of operating, by the curved bistoury, is simple and very easily performed.

Mr. Cock had but a few observations to make, in reply to those that had fallen from the other speakers. The operation in question was recommended by him and others as a means to rescue patients from the effects of retention, when all other measures had failed. Some misapprehension appeared to have arisen from the number of cases he had brought forward. If all had been read—which was not the case—it would have been seen that his own cases were only 24 in number, and that the others had been furnished by his friends and colleagues, Messrs. Cooper, Birkett, Poland, and others, and were marked separately in his paper accordingly. Some of the remarks that had been made would lead to the conclusion, that he had been rash in operating, but he could assure the Society that he had only had recourse to the puncturing of the bladder by the rectum as a last resource, except in cases of old impermeable, hardened strictures, with the perinæum in the same state. The cases he had narrated extend over a considerable number of years, and he might state that, when he was assistant-surgeon to the hospital, he had seen every case of retention of urine that presented, and there were often two or three a day, nor did he believe that at this aristocratic end of the town such cases of impermeable stricture were met with as were seen in the more easterly portion. He thought he had shown that this operation was only to be had recourse to in the worst cases, when every other palliative measure had failed; indeed, he thought he had often employed palliatives too long. He had spoken of three modes of proceeding for the relief of retention of urine; the first, by the forcible dilatation; the second, by cutting into the urethra between the stricture and the prostate, respecting which he explained its difficiencies and dangers, all of which were very great, and frequently led to failure; and the third and last, which he had mentioned, (without detracting in any way from the utility of the others,) as being more simple, less painful, and more likely to be followed by a cure. The permanence of a fistula had been spoken of as a drawback; but he (Mr. Cock) had never known an instance of this, when the permeability of the urethra had been restored. One of the virtues of the operation, is the obtaining this persistence, as a sort of safety-valve, until a free passage per urethram has been secured; there is often some difficulty in securing its patency until the canal of the urethra allows the urine to flow away through it. Some of the cases which had not been read would illustrate this point. There is not a fistula through which the urine distils; but when the bladder is distended, an impulse to evacuate its contents ensues, and then the urine is discharged in a gush by the rectum, instead of by the urethra. And it is a great comfort to a patient, after enduring the suffering from such a condition of the urinary organs, to be able to discharge the contents of the bladder in a gush. There is one other point to which he (Mr. Cock) should wish to allude. It seemed to be denied by Mr. Coulson and by Mr. Gay, that the relieving this state of those parts places the strictured portion of the urethra in a better condition for a cure to be effected than previously existed. This denial did not accord with the results of his own experience; every operation by means of which the contents of the bladder can be more freely discharged than was previously the case, must, sooner or later, place the urinary organs in a better condition, the urethra being relieved from the distress and strain upon it, and, consequently, the induration and other signs of disease gradually lessen and disappear.

PATHOLOGICAL SOCIETY OF LONDON.

Dr. Latham, President, in the Chair.

Dr. Sibson presented a specimen of

RED AND WHITE SOFTENING OF THE RIGHT HEMISPHERE OF THE BRAIN,

and gave the following history of the case:—E. B., aged 40, was admitted into St. Mary's Hospital, on the 8th of December, 1851, affected with paralysis of the left arm and leg, with which she had been attacked twenty-four hours previously. She was perfectly sensible, and able to give a good account of herself, her speech being quite unaffected. She stated that she had always been delicate, and subject to headache; that two years before, the catamenia suddenly ceased soon after washing her feet; that for about two years she had suffered from headache, affecting chiefly the right side of the head; and that during the last two or three months the pain on the right side of the head was more violent. Her husband, to whom she had been married upwards of a year, states, that she had, during that time, suffered from headache affecting the right side, and during the last four months with increased severity. She had been often drowsy. Her eyesight, particularly that of the right eye, was affected; she was usually wide of the mark in attempting to thread a needle. She vomited at the commencement of the paralytic seizure. When admitted she was pallid, and anæmic-looking. The left arm was quite powerless, and the left leg semi-paralysed. Sensation was perfect. There was no facial paralysis. There was little perceptible change during the 9th, when she stated, that she felt better, and that she had more power in the leg. On the 10th she protruded the tongue towards the affected side, the right side of the tongue being more rigid than the left. She became drowsy and torpid on the 11th, answering questions when roused in a slow, hesitating way. She yawned occasionally; could not be induced to take her breakfast, and passed her urine and fæces in bed. Her evacuations were copious and bilious. The larynx was drawn somewhat towards the left side. The left sterno-cleido mastoid muscle was rigid. The breathing was irregular, slow, and moaning. During inspiration she dilated both nostrils, and during expiration she occasionally puffed. The left masseter quivered; the left arm and leg lay powerless. When the left sole was tickled, the leg was drawn slightly upwards. The pupils were dilated and sluggish; the right eye was turned outwards. On the 12th she lay as if unconscious; when spoken to sharply she opened her eyes, but did not attempt to speak. The respiration was occasionally stertorous and puffing, occasionally moaning. The left sterno-mastoid was relaxed; the right arm somewhat rigid; the month firmly closed. When the urine was drawn off she moved her right arm and leg, as if semi-conscious. On the 13th, respiration was irregular, with constant moaning, and occasional stertor. The extremities were rigid; the face was flushed; the pulsation of the right carotid was strong and visible, while that of the left was feeble. At 3¼ p.m., she lay quite unconscious, and incapable of being roused, the right pupil being dilated, the left of medium size. The right nostril was permanently fuller than the left, which did not act in the least. The left angle of the mouth was lower than the right, the puffing expiration being usually limited to the left side of the mouth. The left sterno-mastoid was relaxed and did not act during inspiration. The right sterno-mastoid was rigid, and acted freely during inspiration. The larynx was in a central position. There was general moderate stiffness of the limbs. The left arm was moderately rigid, especially the biceps and flexor muscles—the fingers being semi-bent, while the triceps and extensors were relaxed. Reflex movements of the leg were excited by tickling the sole. The pulse was very irregular—12 in the first ten seconds, and 22 during the succeeding ten seconds. This irregularity corresponded with the very irregular respirations, which were sometimes seven, and sometimes thirteen, in twenty-five seconds. The inspirations were deep; each expiration was accompanied by a groan, which was stronger and more struggling when the respiration and the pulse

were simultaneously quickened. The movements of breathing were exactly equal on both sides, varying everywhere, according to the depth of the inspiration, from 6 to 20-100ths of an inch. The abdominal muscles were powerfully contracted during each expiration, when the rigid walls on each side protruded outwards. Hence, during each inspiration, although in front the abdominal walls advanced freely about a quarter of an inch, yet at the sides they fell in, owing to the relaxation during inspiration of the previously rigid abdominal muscles. The right and left scalenus acted during inspiration with equal power. At 4.50 p.m., her pulse was small and weak, the breathing noisy, from the excessive quantity of adhesive saliva and mucus which filled the mouth. The respirations became less and less frequent, and she died at 5 p.m.

Post-mortem Examination, made Forty-six Hours after Death.—The body is muscular and well formed. There is congestion of the right side of the head under the scalp. The calvarium is very thick anteriorly. The vessels over the left hemisphere are distended with blood. Under pressure, the whole left hemisphere is firm; but the right, which is not congested, is soft, pulpy, and yielding over its three anterior fourths. The anterior three-fourths and the superior two-thirds of the right hemisphere are throughout affected to a greater or less degree with red, fawn-coloured, and white softening. Just above the level of the corpus callosum in the medullary structure there is an oblong patch of softening of a dusky-red colour, nearly two inches in length and three-quarters of an inch in breadth. There is a white layer of medullary structure interposed between the grey matter of the convolutions and the patch in question, the outline of which is projected, as it were, in points between the curves of grey matter covering each convolution. The grey matter of the anterior and lateral convolutions is throughout more or less affected, being everywhere softened, and in some parts pale, in others of a dusky violet or red, especially at the recesses of the convolutions. One large deep convolution at the posterior and lateral part of the brain is affected to an unusual degree. It is soft, and streaked throughout of a dark dusky-red, and is deepest in hue at the surface. This convolution forms a red mass of about the size of an oblong walnut. In the medullary structure, which is throughout soft, but entire, there are below the large oblong patch described above several smaller patches of red softening—one of them is of a reddish pink colour, irregular, of the size of a pea, in the middle of the anterior lobe. Another reddish patch, of the size of an almond, is seated just outside the posterior part of the corpus striatum. Behind this is a fawn-coloured spot of the size of a sixpence. Close to the anterior part of the corpus striatum there is in the medullary structure a ring of red softening, with a fawn-coloured centre, the size of a peppercorn. In the anterior portion of the corpus striatum there is a patch of red softening, of the size of a pea. The greater part of the right corpus striatum, and the whole right thalamus, appear healthy. The left hemisphere is firm throughout, and the grey structure is unusually dark; but there is an exception in one of the lateral convolutions, the grey substance of which is markedly thin, firm, and pale. The whole of the base of the brain, the cerebellum, the pons, and the medulla, are firm, the grey matter being everywhere, both in the convolutions and the central masses, unusually dark. The left choroid plexus is more injected than the right. Under the microscope, the capillaries are congested, and the minute arteries ramifying through the posterior convolution affected with red softening are observed many of them to have their walls studded with minute fatty granules. Some of the vessels are universally thus degenerated; others only in patches; while others are quite free from all abnormal sign, being perfectly white and semi-translucent. Some fatty granular corpuscles were mingled with varicose nerve tubes, with large fat corpuscles, and with a few red amorphous masses. There is much frothy mucus in the bronchial tubes. All the cavities of the heart are empty. The liver is small and congested. The kidneys are lobulated and congested, their capsules, especially that of the left, being thickened. There are no other notable changes.

Dr. Handfield Jones gave the following description of the microscopic appearances observed by him in certain portions of the softened tissue. In the convolutions of the hemispheres there were spots or patches of a red colour, portions of which under the microscope showed extreme congestion everywhere of the capillary plexus, and apparently small extravasations at various points. In the tissue around there were very numerous granule cells of different sizes, and some large patches of the oily-looking matter which enters so largely into the constitution of the granule cell; here and there the larger vessels (not so much the capillaries) were coated with the same matter.

Dr. Sieveking exhibited some beautiful drawings of the affected cerebral arteries.

Dr. Quain asked Dr. Sibson, whether he considered that the softening of the brain depended on disease of the vessels, or was the result of inflammation; if he thought the latter was the case, what were the grounds on which he came to that conclusion?

Dr. Sibson had no doubt the case was one of inflammation, from whatever cause it might originate. Many of the vessels were perfectly healthy; the disease was not due to the general condition of the blood-vessels, but those in the parts where softening had taken place, partook of the disease, and were in a state of fatty degeneration. By keeping to the use of the term "red softening," all difficulty was avoided. With respect to the symptoms:—the right side of the head and face was more congested, and the carotid beat more violently on that side than on the other, with other signs indicative of determination of blood to the head. He (Dr. Sibson) was not able to speak decidedly of the state of the blood-vessels at the base of the brain, but they seemed to be perfectly healthy. The structure of the brain itself appeared to be healthy, but the grey part was everywhere darker than usual, the white texture being apparently normal. The membranes were evidently thinner than they are generally found to be, and somewhat more congested.

Dr. Handfield Jones said, that the question of inflammation was set at rest by the presence of the granular cells. Dr. Bennett, of Edinburgh, has shown that they are not found in cases of non-inflammatory softening of the brain, and only in those where the *ramillossement* is owing to inflammation.

Dr. Quain presented, for Dr. Meryon, a specimen of

PERFORATION OF THE INTESTINE IN A CASE OF TYPHOID FEVER.

Two cases of typhoid fever (with rose spots) had occurred in the house in which the child, aged 5½ years, from which this specimen was taken, resided. The little patient, a girl, had been ailing for a week or more, when Mr. Wright, of Brixton, saw her. Her symptoms were—heat and dryness of the skin, dryness of the lips, white furring of the tongue, great thirst, slight headache, much vertigo, pulse 110 to 120, urine high coloured, three or four yellowish or brownish motions daily, no pain of the abdomen, on which there were five or six rose-spots. She had slight cough, with a little sonorous and mucous râle over a part of the chest. During the second week she had increase of diarrhœa, and some delirium at night. On the 13th of December, Mr. Wright was called up at night in consequence of the patient being seized with a sudden increase of pain in the hypogastric region. She had had within the previous hour four copious yellow liquid stools, accompanied by griping and general pain over the abdomen. There was no marked tenderness on pressure over the abdomen. Chalk mixture with tincture of opium gave temporary relief; but the marked alteration of the countenance, and the increased rapidity of the pulse, led to an apprehension that perforation had taken place, though there was no tenderness on pressure. At 10 next morning, she complained, in addition, of occasional shooting pains in the region of the bladder. At 8 p.m., there was collapse of the features, exquisite tenderness of the abdomen, especially in the hypogastric region, rapid pulse, vomiting, and diarrhœa, which continued until within an hour of death, which occurred at 7 o'clock on the following morning,—that is, twenty-nine hours after the sudden accession of pain, and on the thirteenth day of decided fever.

Post-mortem.—General peritonitis, with effusion of lymph in the abdominal cavity. Ulceration of several of Peyer's patches. In one of these, about four inches from the cœcum, perforation had taken place; but little of the contents of the intestine had escaped through this opening.

At the close of the meeting, the President nominated Dr. James Bird and Mr. Mitchell Henry as auditors of accounts, and the nomination was ratified by the members present.

MEDICAL NEWS.

University of Oxford.—The deputy-reader in geology (Mr. H. E. Strickland, M.A., Oriel) commenced a course of lectures on the 27th inst., at 1 p.m., at the Geological Museum in the Clarendon. These lectures will treat of the first principles of geology, illustrated by the chronological succession of the stratified deposits from the earliest ages to the present time. The Regius Professor of Botany, Dr. Daubeny, will begin his course at the new lecture-room, contiguous to the Botanic Garden, on the 5th of May, at 2 p.m. The lectures will be continued twice a week (Wednesday and Friday).

University of Cambridge.—Medicine.—The examinations for the licence *ad practicandum in medicinâ* will commence on the

24th May, at 10 a.m, at the Arts' School, under the Public Library, and will continue on that and the three following days. Candidates for the degree of Bachelor of Physic will be examined, at the same time, by the Regius Professor of Physic, the Professor of Anatomy, and the Downing Professor of Medicine. Gentlemen intending to offer themselves for examination are requested to signify the same to the Regius Professor of Physic, on pathology, on or before the 17th May. The lectures by the Regius Professor of Physic will recommence on the 21st of April.

Royal College of Surgeons.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 23rd inst.:—

Barnard, George, Bath.
Brand, Samuel Elwin, Aldersgate-street.
Day, Robert Newcombe, Chudleigh, Devon.
Dodwell, William Henry, Hammersmith.
Gane, Henry James, Bath.
Gange, Frederick Abner, Dover.
Gramshaw, Joseph John Hill, Bristol.
Heelis, Robert, Limehouse.
Hoare, Francis Legerson, Cahersiveen, Kerry.
Masfen, William Edward, Stafford.
Mercer, Thomas Hopkins, Alderley, Gloucestershire.
Pearse, Robert Bryant, Bath.
White, Nicholas Warburton, Macroom, Co. Cork.
Wills, John, Donhead, St. Andrews, Wilts.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 22, 1852:—

Adams, Edward Burman, Bungay, Suffolk.
Armstrong, Henry Baker, Brecon, South Wales.
Attfield, George.
Cumning, Robert Butterfield.
Duncan, William, Amble, Northumberland.
Godfrey, Benjamin, Grosvenor-place, Camberwell.
Smith, Louis Lawrence.
Tickell, John Hender.

Marischal College and University, Aberdeen.—Prizes in Medical Classes.—*Practice of Medicine.*—Senior class. John P. Stratton, Perthshire, Eglinton Prize. Junior Class. Edward W. Skues, Aberdeen, ditto. *Institutes of Medicine Class.*—George S. Ogg, Aberdeen, Eglinton Prize; Walter S. Gervis, Devonshire. *Medical Jurisprudence Class.*—Edward W. Skues, Aberdeen, Eglinton Prize. *Midwifery Class.*—Edward W. Skues, Aberdeen, Eglinton Medal; George Baillie, Edinburgh, ditto; John P. Stratton, Perthshire, Class Medal. *Surgery Class.*—John P. Stratton, Perthshire, Eglinton Medal; Francis N. Lucas, Calcutta; John Ogilvy, Aberdeen. *Anatomy*—Senior Class.—George S. Ogg, Aberdeen, Eglinton Medal; Francis N. Lucas, Calcutta, Honorary Certificate; Alexander M. Humphrey, Aberdeen, ditto. *Anatomy*—Junior Class.—Walter S. Gervis, Devonshire, Eglinton Medal; Paul H. M'Gillivray, Aberdeen, Honorary Certificate; George G. M. Millar, Aboyne, ditto. For good conduct, awarded by the Class, Henry T. Sylvester, South Wales. *Chemistry Class.*—William Walker, Aberdeen, Eglinton Prize; Thomas F. Peppe, Aberdeen; George S. Ogg, Aberdeen; Hugh R. Meiklejohn, Strathdon. On the 13th and 14th April, the following students underwent and passed part of their examinations for Medical Degrees, viz.:—Francis N. Lucas, Calcutta; Henry T. Sylvester, South Wales; John Ogilvy, Aberdeen; Walter S. Gervis, Devonshire; William B. L. Grant, Aberdeen; William Watson, Aberdeen. On Friday, the 16th inst., after the usual examinations on preceding days, the degree of Bachelor of Medicine was conferred on Alfred W. K. Packman, Hertfordshire; Charles D. F. Phillips, Edinburgh; Edward W. Skues, Aberdeen; George Baillie, Edinburgh; John P. Stratton, Perthshire; William M. Dickinson, Devonshire; William Stewart, Perthshire. And the degree of Doctor of Medicine was conferred on Alexander Wilson, Dumfriesshire; Archibald F. Richmond, Renfrewshire; Archibald Simpson, A.M., Aberdeen; David Johnston, A.M., Kincardineshire; George H. Smith, Edinburgh; James Laing, Perthshire; Samuel B. Denton, Yorkshire. For the situation of Assistant-surgeon in the Honourable the East India Company's Service, offered by the Chairman of the Company, there appeared two candidates—Archibald Simpson, A.M. and M.D., Aberdeen, and John Proudfoot Stratton, M.B., Perthshire. The competition was concluded on Saturday, the 17th inst., and on Monday, the 19th, the Examiners in the several departments of Medical Science, nine in number, having given in their report, both candidates were unanimously found to be highly qualified for the situation referred to, but Dr. Stratton to be, upon the whole, the superior. It was accordingly resolved to recommend him to the Chairman of the Honourable Company.

Medical Appointments and Vacancies.—The surgeoncy to the Exeter Dispensary is vacant, through the resignation of Mr. Amory. Messrs. Caird and Roberts, of Southernhay, Mr. Roper, and Mr. Hartnell are candidates for the vacant appointment.—At the Middlesex County Lunatic Asylum, at Colney Hatch, a resident medical officer is required for the female department. He must be an M.D., fellow or licentiate of one of the British Colleges of Physicians, or a member or Fellow of the Royal College of Surgeons, and L.S.A. Salary, 200*l.* a-year, with board, and an allowance for coals and candles. Services to commence in the middle of June next. Testimonials to be sent in on or before the 17th of May; date of election, the 18th.

Military Appointments. — 33rd Foot: Assistant-Staff Surgeon Alexander Mackay Macbeth to be assistant-surgeon, vice Webster, who retires.

Naval Appointments.—Mr. W. H. Clarke, assistant-surgeon of the Centaur, flag-ship of the Rear-Admiral Henderson, in the River Plate, is appointed to the Locust, vice Mr. Patrick, who was to leave the Brazil station in the first vessel for England.

India.—Assistant-Surgeon Swift, of the 98th, is destined for the Bengal Presidency. Second Class: Staff-Surgeon Burton, of the Garrison Hospital, Chatham, has accompanied a portion of the 20th regiment, *en route* for Canada.

Obituary.—On the 7th February, Dr. William G. Nelson died at his residence in Cambridge, New York, aged forty-three years. His disease was congestion of the brain. His illness was of short duration, and the intelligence of his decease fell with startling suddenness upon the large circle of his friends. He was born at Ryegate, Caledonia County, Vermont, in March, 1808. His medical education was obtained at Dartmouth College, where he stood high in the estimation of the professors. Dr. Massey, the Professor of Surgery and Anatomy in proof of this, appointed him first Demonstrator of Anatomy, and afterwards Professor of Surgery. Dr. Nelson afterwards attended lectures at Harvard University. He also spent some time as surgeon to Chelsea Hospital in Boston, where he devoted himself with much zeal to the acquirement of that knowledge and skill for which he became afterwards so eminent. On giving up his appointment at that hospital, he settled in Barnet, Vermont, where he remained until 1845, when he removed to Cambridge. In both places he enjoyed a large practice, and obtained a wide-spread popularity, both as a physician and as a surgeon. On the 7th inst., John B. Chamberlin, M.D., at St. Clair, Michigan, U.S., aged 75. Dr. Chamberlin, after the completion of his classical and medical education, practised successfully for many years in the district of Quebec, Lower Canada. At the breaking out of the war in 1812, refusing the allegiance required of him by the British Government, (he was a native-born American, U. S.,) he abandoned the position he had obtained in Canada, and, returning to the United States, established himself at Auburn, New York. In 1816, removing from Auburn, he became a resident of Michigan; and first at Detroit, subsequently at Mount Clemens and Pontiac, through many years, by skilful professional labour, made himself widely, as well as honourably known to the pioneers of the Peninsula. The *Detroit Advertiser* says of him, "The native vigour of his intellect was aided by a constant spirit of observation and inquiry; and a remarkable power of expression rendered his conversation always impressive to the minds of others." On the 14th inst., Dr. Henry Davies, for many years President of Hamilton College, died at Clinton, Oneida county, aged 51. On the 24th inst., at Aldermaston, Berks, Francis Cox, Esq., surgeon, in the 54th year of his age. At Guernsey, on the 9th inst., Francis P. Hutchinson, Esq., late Surgeon in the Royal Artillery, aged 68.

Royal Medical and Chirurgical Society.—At the last meeting of the Society, Dr. John Hall Davis, Dr. Robert James Hale, Dr. Walter Hayle Walshe, and Mr. Merryweather, were elected Fellows.

Medical Benevolent College.—We are happy to state, that a sermon was preached by the Right Rev. the Lord Bishop of St. Asaph, on Sunday last, in the church of the Holy Trinity, Brompton, in aid of the funds of the Medical Benevolent College, and that the proceeds resulting therefrom were highly satisfactory. We have also pleasure in adding, that the claims of the Medical Profession upon the public, in connexion with this important charity, are now being felt and properly responded to, and that those whose circumstances render them cognizant of the gratuitous services and private charity of the Profession readily avail themselves, through the medium of this excellent Institution, to testify their appreciation of the services alluded to.

ORIGINAL LECTURES.

CLINICAL LECTURE

GIVEN AT

St. George's Hospital,

By H. BENCE JONES, M.D., F.R.S.

Physician to St. George's Hospital.

BRIGHT'S DISEASE.

Gentlemen,—There are at present two cases of Bright's disease in the hospital to which I wish to-day, at the conclusion of my course, to direct your attention.

The points to which I shall chiefly advert on this occasion are, first, the relation of the microscopical sediment which exists in the urine, to the duration and intensity of the symptoms during life, and to the morbid appearances likely to be found in the kidney after death; secondly, the complications which exist in these cases and in the disease generally; thirdly, the treatment of the general symptoms and of the complications of the disease.

First, then, of the indications to be derived from the microscopical examination of the urine. I pass over the chemical examination and other points of interest, only in order that I may have more time for the special objects of this lecture.

In the *Medical Gazette* for June 13, 1845, page 270, you will find a short paper of mine, giving an account of the history of a peculiar microscopic deposit in albuminous urine, first observed by Professor Schönlein, of Berlin. There is an engraving also of the same kind of deposit, as it appeared in a patient with Bright's disease in this hospital in May, 1844. The account of the microscopical deposit is thus given by the late Dr. Simon, in his Beiträge:—

"The following different appearances may be recognised:

"1. Mucous globules of the ordinary size. Partly granulated. Partly clear. Nucleus very distinct.

"2. Laminar epithelium from the mucous membrane of the bladder.

"3. Blood-globules.

"4. Round dark globules filled with granular substance, in diameter varying from $\frac{1}{1000}$th of an inch to $\frac{1}{1111}$th of an inch.

"5. Tubes or amorphous matter adhering in the form of tubes. These tubes for the most part have an actual covering, and are cylindrical, as may be seen by causing them to revolve in the urine. Sometimes this covering is wanting, and then an amorphous slightly granular matter, adhering like a cylinder, is seen. The true cylinders are sometimes quite full, sometimes empty. The cylinders which are full contain sometimes a light, at other times a dark granular matter. The breadth of the cylinders varies; the broadest are $\frac{1}{500}$th of an inch, the narrowest $\frac{1}{1000}$th of an inch."

In the same paper, I have stated, that I found these cylinders in the slightly albuminous urine of a comparatively healthy man, who was passing oxalate of lime.(a) I remark on this, "that I cannot consider it probable, that irritation caused by oxalate of lime in the urine leads to the effusion of fibrin and albumen from the parietes of the urinary ducts. Nor can I agree with my friend Dr. Scherer, that these cylinders are analogous to the fibrinous coagula in croup, and that they result from inflammation of the ducts. It seems to me most probable, that congestion causes the effusion of the liquor sanguinis into the urinary ducts; that thus fibrin as well as albumen are effused together, and that the fibrin coagulating in the ducts produces the cylinders and the granular matter within them."

"Further experience," I conclude, "may show, that simple congestion alone, without granular disease, is indicated by these cylinders; but at present, from their invariable appearance in Bright's disease, I should, when I met with them in the urine, always suspect that granular degeneration of the kidney was taking place."(b) No good attempt was made to connect the appearances in the urine with the state of the symptoms or with the supposed stage of the disease of the kidney. It is self-evident, that if such a connexion can be proved to exist, it will be an advance of our knowledge, which, for prognosis, if not for the treatment of the disease, would be most desirable.

To establish this relationship between the deposit and the disease was and is worthy of every endeavour. To Dr. George Johnson the credit is due for first attempting the solution of the problem in this country; and, even if he did not succeed, yet an unsuccessful arrangement is better than no arrangement at all. His first statement was, that the microscopic appearance of oil-globules, partly free and partly contained in epithelial cells which have escaped from the urinary tubes, is the most important evidence of that fatty degeneration of the kidney which constitutes Bright's disease. This simple view, that Bright's disease consisted in fatty degeneration of the kidney, and that the appearance of microscopic fat and oil in the urine was diagnostic of Bright's disease, was soon rejected, even by Dr. Johnson himself. He then stated, that there were two distinct forms of fatty degeneration, and that there were other kinds of degeneration, consequent upon inflammation, which were characterised by increased number of slightly altered epithelial cells in the urine. He extended his first view thus:

"I have now distinguished four conditions of the kidney—

"1. Acute desquamative nephritis.

"2. Chronic desquamative nephritis.

"3. Simple fatty degeneration.

"4. Fatty degeneration with desquamative nephritis."

In the same paper, he also states that the kidney is liable to other diseases of an inflammatory nature. In one class of cases, pus has been chiefly present in the urine and in the kidney; in another and a distinct class of cases, blood. "The diagnosis of each of these conditions of the kidney may be made with ease and certainty by a microscopic examination of the urine."

Here, then, by the microscopic examination of the urine, it is thought that six or seven different forms of disease of the kidney can be recognised; and as it is in the highest degree probable, that if there be different forms of disease there may be different symptoms and different modes of treatment, it becomes very important to know how far the separation and classification of the forms of disease and of the sediments is true.

Now, the first and most important objection to the view above given is, that the microscopic sediment in the same case, during the progress of the disease at different periods, is found to vary exceedingly. Even the variations of the appearance of the urine and of the quantity of albumen, as determined by chemical analysis, are very considerable in the same case at different times; and so also the microscopic sediment varies considerably in the same case. Sometimes blood, sometimes pus, sometimes tubular casts, with epithelium in varying quantities; sometimes all microscopic sediment is absolutely wanting, so that, after the most careful endeavour to collect the sediment (if any were present), I have altogether and entirely failed to detect any microscopical evidence whatever, although the chemical evidence has been decided enough. At other times, microscopical appearances have easily been discovered, but they have been so variable, that at one time I might have called the case one of acute desquamative nephritis, and at another time fatty degeneration.

This primary objection has occurred to others as well as to me, and I cannot, therefore, agree in the statement, that the microscopic examination of the urinary deposit enables us to decide on the presence of different kinds of degeneration of the kidneys. On the contrary, it appears to my observation, and to my reason, far more probable, that in Bright's disease there is but one degeneration of the kidney, and that different states of congestion and inflammation give rise to the different microscopical appearances of the urine.

Take, for example, the phenomena observed after irritation of the skin, or inflammation of the pleura. First, congestion, without effusion or deposit; then, when the irritation is rather more, the congestion increases, and a watery blister or effusion forms, which may contain no trace of fibrin. If this fluid passed off, mixed with the urine, we should find that the urine was albuminous, without any trace of fibrinous casts or granular deposit. Suppose the congestion to be still more, the blister or the pleura then

(a) Though seven years have nearly passed since this observation was made, no further symptoms of any complaint have manifested themselves.

(b) I have known albumen and fibrinous casts to occur in the urine during pregnancy, with no other bad symptoms whatever. After delivery both disappeared from the urine, and five years afterward the woman was in good health. On the other hand, dropsy commencing during pregnancy, has many times, to my knowledge, been the commencement of Bright's disease, which has ended fatally.

would contain, not only albumen, but fibrin also. The liquor sanguinis, which consists of fibrin dissolved in the albumen, would be poured out.(a) If this occurred in the kidney, instead of in the skin or pleura. fibrinous casts would appear in quantity proportioned to the extent of the congestion, and the duration of this deposit of fibrin and albumen would depend on the duration of the congestion. Still greater congestion, or a more violent attack, would lead to the effusion of blood globules; and, when a further stage of inflammation supervened, pus globules would be found, in addition to the fibrin and albumen. Obstruction is the consequence of congestion and inflammation, and, from whatever cause the obstruction may arise, it causes fatty matter to accumulate ; and thus the deposit of fatty matter frequently, if not always, is the consequence, and not the cause, of the degeneration.

Let me. for a moment, take you to another disease of the kidney, (differing from Bright's disease,) in which I am certain that a greater or less degree of congestion does produce different deposits in the urine. In this complaint, I am certain, if you subdivided the disease according to the appearances in the urine, you would greatly err.

In the so-called chylous urine, occasionally, for many days, no blood globules, no trace of fibrin, no fat even, may appear; but chemical re-agents may show that albumen is present, and that the quantity of albumen in the urine is increased after exertion.

In the same case, at a different period of the disease, in addition to the albumen, fibrin will be present in the urine. It may be to so great an amount, that the bladder will be full of coagulum; and, at another time, to so small an amount, that only after the urine has been made for an hour or more will a fine coagulum be seen to form. If still more congestion of the kidney is present, blood globules in considerable quantity will appear, and their different deposits will alternate or be simultaneous, according as the congestion varies. It appears to me to be very probable, that in this so-called chylous urine the mammary processes of the kidney may be the seat of the congestion; while, in Bright's disease, it is more probable, from the deposit in the cortical structure, and from the appearances seen when the kidney is injected, that the secreting structure is the congested part.

I cannot, then, at present admit, that there are different diseases confused together under the denomination of Bright's disease ; but I consider that the different appearances in the urine and the different appearances in the kidney arise from the same disease in different stages and states; sometimes in an early stage, at other times in a far advanced stage. Now, in one stage, in a state of the slightest possible congestion or inflammation ; then, in the same stage, in a state of such congestion or inflammation that extravasated blood or purulent matter may be found mixed with the degenerated structure.

If you ask, first, in what does this degeneration consist? and, secondly, where is it seated? I am unable at present to give you a perfectly satisfactory answer. To the first question I reply, in chronic inflammation ; and to the second, in the capillary vessels which surround the tubes. In other words, I consider that Bright's disease corresponds to chronic pneumonia, and not to chronic bronchitis. Even in the state of inflammation which follows scarlet fever, I cannot consider that there is an affection of the urinary tubes consequent on the desquamation resulting from the removal of the poison of scarlet fever by the kidneys. I cannot consider that the elimination of an unknown poison is the cause of this or of other affections which at the end of scarlet fever are apt to arise—for example: inflammations of the eye and the ear. If the blood is in a state of increased fibrin, even when the blood globules are diminished, inflammation will most readily arise, and the slightest cause that produces a congestion here or there commences a local inflammation.

In the few cases in which I have seen the commencement of Bright's disease, there has been a preceding state in which inflammation was most liable to supervene.

Three such cases I have now before me. The first was a young man, who, when in perfect health, was attacked with pleurisy, which ended in empyema. He was tapped, and after many months, albumen, which was previously absent in the urine, appeared in small quantity, and rapidly increased, dropsy supervened, and the patient quickly died.

The second case was that of a young man with phtbisis. No trace of albumen was perceptible in the urine for some months after the phthisical symptoms appeared. The albuminous urine came on six weeks before his death.

The third case was that of a young woman with great disease of the mitral valve and hypertrophy of the heart. She had some obscure head symptoms, for which the urine was examined, but no albumen could be found by me or by others. Some months afterwards I was again called to the same patient. I found the urine highly albuminous. The head symptoms had changed into fits,—into epileptic seizures with tendency to coma, in one of which the patient died.

In all these cases that state of blood existed which, as I have so often told you, precedes and predisposes to inflammatory attacks.

You must not suppose, that because I think that there are not different diseases confused in the term Bright's disease, that, therefore, I recognise only one disease of the kidney. The kidney is without doubt liable to many kinds of disease. I have spoken of one which leads to the so-called chylous urine. There is another which ends in the formation of cysts, the wrongly called hydatids of the kidney, which is totally different from Bright's disease.(a) Then there is an infiltration of fibrin into the cortical structure of the kidney, similar to that infiltration which frequently occurs in the spleen, when there is a deposit of fibrin on the valves of the heart. Then there is the scrofulous disease of the kidney, a form of disease which may occur with Bright's disease, as tubercles in the lungs may be accompanied by pneumonia. Then there is the disease of the mucous membrane of the pelvis of the kidney and of the tubes (corresponding to bronchitis), which frequently results from dilatation and inflammation consequent upon obstruction of the urethra or ureter. Then there are malignant diseases. I mention these only to show you that there are many distinct diseases; and I may here remark, that the detection of the chemical and microscopical characters of the urine which is passed when these diseases exist in the kidney, is of more importance for prognosis and treatment than the determination of the different states and stages of Bright's disease.

2ndly. I must pass on now to the complications which exist in the two cases in the house and in the disease generally.

In the one case there is only chronic rheumatism of the joints. In the other there has been pericarditis, pleurisy, epistaxis, and at times most urgent vomiting and diarrhœa.

Though serous inflammations are most common, still, not unfrequently, inflammations of mucous membrane are met with complicating Bright's disease. I know scarcely any disease that I have not seen as a complication of Bright's disease. I do not say related as cause and effect. That relation would be most difficult to determine with certainty. In some of the rarer complications it would be quite impossible to do so. Thus, not many weeks since, you might have observed in the house a case of mania; the same patient had dropsy and albuminous urine. The same complication I have again seen, very lately, in the case of a lady who for three years has been known to pass albuminous urine, and now violent manial symptoms have come on.

In other complications the connexion may be fairly established. Take, for example, the head symptoms, which arise from the constituents of the urine not being thrown out of the blood. This complication is the most frequent, the most interesting, and the most dangerous which can occur. Urinary poisoning, it may be called, for shortness. You have often, probably, heard it said, that urea in the blood caused the symptoms of poisoning; but there is good reason for doubting whether urea is the only, or indeed the chief poison.

In the first place, it has been observed, that frequently a very great excess of urea has been found in the blood, and yet no poisonous symptoms have been present. Secondly

(a) Thus, lately, in St. George's Hospital, a patient of mine, with pleurisy and effusion, was tapped, and a clear, greenish coloured liquid ran through the canula. The following morning, on taking the liquid for closer examination, the whole liquid was found to be coagulated. By agitation, the coagulum was easily broken up. The fluid was alkaline, highly albuminous specific gravity 1020, free from pus globules; the amount of fibrin was small, though it was sufficient to coagulate all the liquid.

(a) I am indebted to Dr. Beith, R.N., for the fact, that very many of the Greenwich pensioners, who each winter die from pneumonia or bronchitis, are found to have these cysts in the kidney. Most commonly no disease of the urinary organs has been known or thought of during life, very many being in good health up to the time of the commencement of the inflammation of the lungs.

The following experiment has been made by Dr. Frerichs:—"In the afternoon, the kidneys of a dog were extirpated. The following day it appeared perfectly well. Twenty-four hours after the operation, 31 grains of urea were injected into the jugular vein. In an hour the dog was restless, and vomited frequently; soon after, convulsions came on. The vomited matter contained ammonia, and in two hours and a quarter the dog died. The blood contained ammonia.

A second experiment is thus described:—At a quarter past three, both kidneys were extirpated, and then 46 grains of urea was injected into the jugular vein. At half-past four the dog became comatose, and the expired air gave thick fumes when hydrochloric acid was brought near to the nose. At six o'clock ammonia could not be detected in the expired air; the dog again became lively and got up. The following morning it was found dead.

Another dog had only 31 grains of urea injected after extirpation. Two hours and a half afterwards no ammoniacal vapours were expired, and the dog showed no symptoms of poisoning. The following morning it was found dead.

Three other dogs had 46 grains of urea injected. In all of them ammoniacal vapours were found when the symptoms of poisoning occurred.

Dr. Frerichs also made the following comparative experiments, by injecting carbonate of ammonia into the jugular vein:—

A filtered solution, containing from 15 to 30 grains of carbonate of ammonia was used. The injection took place very slowly. The dog howled and fell into a state of deep stupor, with occasional convulsions. The breathing was difficult, and the expired air was loaded with ammonia. The coma lasted three hours, during which time vomiting occurred twice. Afterwards the dog became again lively.

Another smaller dog was immediately seized with violent convulsions, which lasted three minutes; then it vomited and became comatose. The following morning the dog was as well as ever.

Three other dogs had immediate convulsions; after two or three minutes they became comatose. When more carbonate of ammonia was injected fresh convulsions ensued; these were again followed by coma. After many hours the dogs recovered.

From these and other experiments made at Göttingen, Dr. Frerichs arrived at the conclusion, that urea must not only be present in the blood, but that some agent must also cause the urea to change into carbonate of ammonia.

$$C^2\,N_2\,H_4\,O_2 + 4HO = C_2\,O_4 + N_2\,H_8\,O_2 = 2(CO^2 + NH^4\,O)$$

In confirmation of his theory, he states, that ammoniacal vapours are constantly exhaled by those who have head symptoms with Bright's disease.

He gives the following Table, to show how frequently death ensues from this complication:—

Total Number of Deaths in Bright's Disease.	Observer.	Number of Deaths from Urinary Poisoning.
70	Bright	27
10	Bright and Barlow	2
36	Gregory	17
16	Christison	10
49	Rayer	3
6	Martin Solon	2
33	Malmsten (Sweden)	20
21	Frerichs	5
241		86

To which I may add, from eighty-two cases of Bright's disease which have been under my care in St. George's Hospital, from the 22nd of April, 1846, to the 31st of December, 1851, the deaths were thirty-six, and, of these, thirteen died with head symptoms.

Whether the urinary poison is carbonate of ammonia, and nothing else, I cannot certainly say. It appears to me most probable that other substances, far more poisonous than carbonate of ammonia, may be produced in the blood in consequence of the insufficient action of the kidneys; and I can well believe that oxalic acid or carbonic oxide might accumulate in the blood instead of carbonic acid; but I have as yet no proof to offer you of the presence of these substances in the blood when the head symptoms occur. Meanwhile, the ammonia theory may be tested by the examination of the expired air in this and other diseases, and possibly also by the presence of nitrous acid in the urine. Hitherto, in cases of Bright's disease, without head symptoms, I have been unable to find nitrous acid in the urine, although when 40 grains of urea are taken by a healthy man, nitrous acid is easily found to be present in the urine.

3rdly. The time warns me to pass on now to the treatment of the complications and of the general symptoms.

The case of chronic rheumatism calls for no particular remarks. With regard to the treatment of the pericarditis and pleurisy, the special point to which I desire to direct your attention is, that no mercurial has been ordered.

The intense action of mercury in Bright's disease has so frequently and so forcibly been presented to my notice, that I have formed a general rule never to give mercury in cases of albuminous urine. I have seen the most violent salivation from single doses even of grey powder, and on this account, even in serous inflammations consequent on Bright's disease, I advise you not to give mercury. Why mercury should act so energetically in this disease is probably explained by the altered state of the kidney. In health, most probably, mercury no sooner passes into the system, than it begins to pass out again by the kidney, like hydriodate of potash or the salts of iron. For example, if a single grain of hydriodate of potash is taken in an ounce of distilled water, in twelve minutes it can be detected passing off in the urine; but, if the kidney is diseased, then most probably this rapid excretion does not so easily take place, and the intensity of the action of this and other medicines may thus be greatly increased.

But, if mercury cannot be used, how is the inflammation to be treated?

The efficacy of counter-irritation is very decided in the treatment of these secondary inflammations. Thus, you will see that blisters form the chief treatment, and the inflammation of the pericardium quickly, and of the pleura more slowly, yielded to this application. But many days had not elapsed when a fresh complication presented itself: violent epistaxis occurred. This yielded to the application of cold, and to gallic acid in ten grain doses, and for a few days no fresh symptoms appeared; but then vomiting ensued, and of all the complications this is one of the most unfavourable, as it usually indicates the commencement of urinary poisoning. It may, however, be also caused by inflammation of the stomach, and in the case before you it probably arises from this cause: at least it has yielded to remedies given on this supposition, and it has been followed by symptoms of inflammation of the colon, of which I shall speak in a few moments. The vomiting was first treated with hydrocyanic acid, and then with creosote; one drop made into a pill with bread was the dose; but though generally this has proved effectual, it was not beneficial in this case. Milk and lime-water were given by teaspoonsful, but the vomiting continued. Small lumps of ice were then ordered, and the vomiting was considerably relieved. It, however, was not removed, but it yielded to a blister; and when it returned, a second blister was applied with great benefit. We come now to the latest complication. The bowels became very relaxed; blood in considerable quantity was passed in the motions; very severe pain was felt when pressure was made above the sigmoid flexure of the colon, while the tongue became more coated, and the pulse more small and hard. Injections of starch, with laudanum; suppositories of compound soap pill; counter-irritation over the painful part, will probably relieve this complication also; but meanwhile the strength decreases, and the increasing heaviness indicates that head symptoms will probably before long occur.

In the treatment of urinary poisoning, I know no single remedy which has produced an effect at all equal to that of a blister on the back of the neck. This appears to me to indicate that there is some local congestion of the brain, as well as some poison in the blood. I have as yet had no good opportunity for trying what the free administration of vegetable and mineral acids can do when head symptoms are present; in one case, large quantities of lemon-juice appeared to have a beneficial effect. The theory of Dr. Frerichs indicates the acid treatment, and it is worthy of a fair trial.

Dr. Watson is, without doubt, right in saying, that these head-symptoms may arise from insufficient supply of blood. Just, as in children, symptoms resembling hydrocephalus may arise from anæmia, when, instead of depletion, counter-irritation and stimulants are required. On this theory, no poison is considered to be present in the blood. The truth, probably, is, that too little blood, too much blood, and

poisoned blood,—each of these states, in different cases, is the cause of the head-symptoms in Bright's disease.

I have only a few minutes for the general treatment when no complication exists. As I cannot make any separation of Bright's disease into different diseases, so I am unable, from observation, to find that different kinds of treatment are desirable. The indications are, first, to relieve the congested kidney; and, secondly, to improve the general health. Gentle but decided action on the skin and bowels appear to me best to fulfil the first indication; cupping, vapour-bath, and elaterium, are the three most energetic remedies; cream of tartar, compound jalap powder, and abstinence from stimulants, are the milder agents. To improve the health, proper air, exercise, food, and small doses of iron, are essential.

Specific treatment by gallic and nitric acid has not benefited my patients in St. George's Hospital. In so-called chylous urine, I know well, the use of gallic acid, in doses of two drachms daily; but, in Bright's disease, when ten-grain doses were given, I have more than once known bad symptoms to occur. In one case, violent convulsions made their appearance soon after the gallic acid was taken. In no case have I found that it stopped the albumen from passing away. I may here mention, that tannic acid appears to affect the stomach much more than gallic acid does.

With regard to the treatment by nitric acid, which has been extensively tried in Germany, I have not found any good result, even when dilute nitric acid has been taken daily for many weeks.

As to the result of treatment, omitting the cases which follow scarlet fever, which constantly recover perfectly, temporary relief is generally all that is obtained. Life may be prolonged for years. Even with ascites, I have known a patient in and out of St. George's Hospital for ten years. Usually, although every complication may be removed, the albumen continues in the urine. The patient resumes his work, and considers that he is recovered; but heat and nitric acid show that this is not the case; and it is only by great care that the tendency to a return of the former symptoms, or to gout, can be prevented.

ORIGINAL COMMUNICATIONS.

THE MECHANISM OF BRONCHOPHONY.

By W. H. WALSHE, M.D.,
Professor of the Principles and Practice of Medicine, University College, London; Physician to University College Hospital; Consulting Physician to the Hospital for Consumption, etc.

§ I. The physical conditions in which morbid bronchophony is clinically observable are:—

1. Increased density of the pulmonary tissue either surrounding pervious bronchi, or forming a medium of communication between pervious bronchi and the spot of the thoracic surface examined,—whether that increase of density be caused by solid, semi-solid, or, perhaps, even liquid, infiltration of the parenchyma.

2. Increased density of texture, produced by extraneous pressure.

3. Presence of any solid extra-pulmonary formation in such a situation as to form a connecting link between the surface examined and a bronchus of some calibre.

4. Increased width and hypertrophy of the substance of the bronchial tubes.

5. Diminished density of the lung, as in the rarefaction of vesicular emphysema.

The diseases referable to the first head are the *common* causes of brochophony; but any hypothesis in explanation of the phenomenon must also apply to the other and comparatively *rare* causes.

§ II. Laennec regarded bronchophony as an essential dependence on increased density of the pulmonary texture, and supposed that it was simply produced by the greater facility with which comparatively dense homogeneous tissue —homogeneous from the exclusion of air—conducted the laryngeal vibrations to the surface.

This explanation is inadequate to meet all the circumstances of the case. In the first place, bronchophony *may* exist, and this to an intense degree, over lung rarefied to such a degree as to give actually almost tympanitic resonance under percussion. Of this fact, (not generally known, or, at least, taught,) I have observed a certain number of examples, where *post-mortem* examination left no doubt of the absence of any textural change in the lung except emphysema. In the second place, as was, I believe, first mentioned in print by Skoda, the voice resounds sometimes with greater intensity, when ausculted over the chest than over the larynx itself. In the third place, the pitch of the bronchophonic differs sometimes distinctly from that of the laryngeal voice. These facts, without disproving the correctness of Laennec's theory as far as it goes, show at least that it requires an addition of some kind to make it include all the varieties of the phenomenon.

§ III. Skoda, holding the general doctrine that the "varying conducting power of the healthy and diseased lung-substance cannot be taken as a basis of explanation of any of the phenomena of auscultation," specially opposes Laennec's views of the mechanism of bronchophony on the following grounds:—

(*a*) Bronchophony may in the course of a few minutes appear and disappear over hepatised lung, the other physical signs, especially the percussion-sound, having undergone no change. (*b*) When vocal resonance thus suddenly disappears, it may as suddenly be restored by making the patient cough or breathe deeply, so as to free the bronchi from fluid in the part of the organ ausculted. (*c*) In cases of pleuritic effusion, the resonance grows weaker and weaker in proportion as the fluid increases; now as the lung grows more and more solid, the greater the quantity of pleural fluid compressing it, the reverse ought to be observed, were Laennec's doctrine of solidification and improved conducting capability well founded. (*d*) If a healthy and hepatised lung be removed from the body, and if, while one person speaks through a stethoscope placed in contact with the surface of each organ successively, a second listens through another stethoscope placed at an opposite point of that surface, the listener will find that more intense resonance reaches the ear through the healthy than the diseased lung.

What is the force of these objections? Let us examine them *seriatim*. (*a* and *b*) Since I first became acquainted with Skoda's statement concerning the appearance and disappearance of bronchophony in hepatisation, I have repeatedly endeavoured to produce artificially the change he describes, but have invariably failed; I have questioned other physicians on the point, and find that they have not observed the alleged variableness in the vocal resonance. I have, however, in one or two instances, noticed intermittent bronchophony occurring spontaneously without the patient having expectorated or even coughed,—a peculiarity evidently of different mechanism from that insisted upon by Skoda, and one to which I will by-and-by return. (*c*) The argument derived from the phenomena of pleuritic effusion seems feeble, and, indeed, unsound. The interposition of a mass of fluid between the condensed lung and the surface alters the terms of the problem completely. It has been shown by Colladon and Sturm, that sonorous rays which reach the surface of water at a very acute angle do not pass into the air, but undergo reflection in the interior of the liquid. Now the angle at which the sonorous vibrations reach the fluid from the bronchi, and ultimately reach the outer surface of the pleural fluid, may very possibly often prove of the degree of acuteness fitted to prevent their passage into the air. At all events Skoda, by ignoring the new influences likely to be exercised by the fluid renders his argument valueless.(a) *d*. The results I have obtained from some experiments on the conducting powers of hepatised tissue, do not agree with those announced by Skoda. First: It is, I admit, quite true, that tissue, called hepatised, may conduct the voice no better, or even less forcibly, than a similar thickness of healthy parenchyma; but it is equally true, that this is not a constant result. I have occasionally found hepatised lungs, taken from the body, conduct the sound with extreme intensity. And these varying results may be obtained from different lungs, which the naked eye would judge to be in the *same* state physically, in regard of their shares of air, fluid, and semi-plastic substance: but it is evident, from the variations in result, that, acoustically, they are in *different* physical states; and that, therefore, such experiments as Skoda's are not to be trusted to. Specimens of parenchyma, apparently identical, are in reality widely different. There can, for example, be little doubt,

(a) Let it not be forgotten, too, that in the interscapular region strong bronchophony is sometimes audible, even where fluid is accumulated in large quantity in the pleural sac.

that varying homogeneousness plays a more important part, than any observable so-called solidification, in regulating the conducting power of the lung. In the varying homogeneousness of different specimens may, in truth, lie the key to the difficulty; but even if so, it is a key which cannot practically be used. Secondly: If, while one person speaks into a stethoscope with its narrow end introduced into the trachea, a second listens over a part of the chest where hepatised lung lies beneath (and where intense sniffling bronchophony existed during life), the listener will often be surprised at the singular and total absence of sound. Skoda, obliged to admit this fact, attempts to evade its force by supposing the vibrations to be interfered with by fluid in the bronchi. To this I would reply, that I have satisfied myself of the total absence of such *post-mortem* resonance over pneumonic solidification, in a case where the bronchi, to the third and fourth divisions, were peculiarly free from fluid, and scarcely any spumous liquid infiltrated the parenchyma—which very same parenchyma, removed from the body, conducted the voice from one stethoscope through another with striking intensity. If we consider the main difference in the physical conditions of the parts, when an individual himself speaks, or when another speaks into his trachea after his death, an obvious explanation of the experimental failures to imitate the bronchophony of life suggests itself. In the dead body, in truth, the laryngeal, tracheal, and bronchial walls take no part in the production or conduction of the sound, which is propagated by their contained air alone; whereas in life the walls of those tubes obviously conduct the sonorous vibrations. But to admit this would have been fatal to more than one of Skoda's hypotheses. Besides, hepatised and healthy lungs are not strictly comparable in and out of the body in regard of this matter: *within the body* the contact of a hepatised lung with the chest-wall is more perfect than of a healthy one; and, admitting that the former is a worse conductor in regard of the condition of its substance, it may be a much better one through the closeness of its union (especially if adhesive) with the parietes. Here is a point which has been totally overlooked by the Viennese physician and his followers.

§ IV. I conceive, then, that, whether Laennec's doctrine be true or false, the arguments just reviewed fail to prove it unsound. Skoda himself naturally thinks otherwise; and, excluding the walls of the trachea and bronchi from all share in the *conduction* of the sonorous vibrations of the chordæ vocales,(a) (an office assigned by him to the contained air of those tubes alone,) maintains that bronchophony is really produced by consonance of the air in the bronchial tubes with the laryngeal voice.

The hypothesis of consonance does not appear to me satisfactory; and it unquestionably fails to meet all the conditions of the problem. The reasons on which I ground this opinion are as follow:—(*a*) Air in any enclosed space does not consonate with every sound produced at its orifice, but only with the fundamental note of that space, and with certain others having a fixed harmonical relationship to that fundamental note,—with certain of its *concords*, in short. This is easily ascertained, in a rough way, by running the gamut with the voice at the mouth of an empty water-bottle; one note only of the octave is at all markedly reinforced by consonance within the cavity,—one or two others, (according to the distance from the orifice at which the vocal sound is emitted, and the depth of the mass of air within the bottle,) very slightly increased in loudness. Now, on the contrary, when bronchophony exists, it is audible with *successive notes* of the octave, standing in no harmonical relationship to each other,—absolute *discords*, in short. These successive notes are to be found at the lowest part of each register, (whether bass, tenor, or soprano;) but the force of bronchophony gradually decreases, not at harmonic intervals, but on *each successive note from below upwards*, until the resonance disappears altogether;(a) and obviously the limitation of bronchophony to grave tones, as contradistinguished to acute ones, has nothing to do with the principle of consonance, but depends upon the difference in the number of vibrations and breadth of the sonorous wave, when notes of these two classes are severally generated. (*b*) Bodies consonate only in unison, or in certain fixed harmony, with the original sound which throws them into vibration.(a) Now, the pitch of the bronchophonic voice varies irregularly from that of the laryngeal with which it co-exists. This difference of pitch is especially to be caught in cases of hepatisation, and is sometimes very striking in amount; the corresponding notes heard in the larynx and on the surfaces of the chest are then, very perceptibly, discords. (*c*) Skoda's exclusion of the tracheal and bronchial walls from all participation in the transmission of the laryngeal voice is at variance both with theory and experiment, and cannot for a moment be acceded to. (*d*) In cases where the bronchophonic voice is very positively and notably louder than the laryngeal, it is difficult to believe, from the mere fact of the intensity of the sound, that the phenomenon can be due to consonance. For a consonating sound, as a rule, is vastly more feeble than the primitive tone eliciting it; and the nicest adjustment of the quantity of air in the consonating body (presuming this to be hollow) is required, in order to produce any serious increase in the amount of intensity. Let it, however, be granted, *argumenti gratiâ*, that chance may sometimes cause the column of air between the larynx and the seat of bronchophony to be of the appropriate length to produce a marked increase of sound,—the doctrine of Skoda gains nothing by the concession. For, be it remembered, Skoda rejects conduction as an element of bronchophony,—bronchophonic voice is, in his apprehension, consonating voice; consonating voice is, then, under the above circumstances, by admission, louder than the original voice. Now, here is an idea irreconcilable with observation; for, it does not appear, that (provided the original and consonating sounds be produced by bodies of the same class, as vibrating strings, hollow bodies, solid plates, etc.) the consonating sound is ever louder than the original tone.(b) (*e*) If the excess of loudness of the bronchophonic over the laryngeal voice were from consonance, *vocal fremitus* (inasmuch as the walls of the consonating tubes must vibrate in the direct ratio of the vibration of their contained air) ought to rise and fall exactly as *vocal resonance*. Now, in point of fact, these two phenomena do not invariably maintain any direct relationship to each other; one may gain, while the other loses, in intensity.

These objections appear to me conclusive against the pure doctrine of consonance, as taught by Skoda, while they show that, if consonance plays any part in the production of bronchophony, it must be a subsidiary, rare, and accidental one. And even this concession is rather made on the ground, that the occurrence of consonance within the chest is not, *à priori*, impossible, than in deference to the arguments actually adduced in its favour.

§ V. From the discussion into which I have now entered, it would follow that the mechanism of bronchophony is probably complex, and certainly not, as the attempt is commonly made to prove it, invariably one and the same.

There are four points which appear especially worthy of consideration: the conduction of laryngeal voice; its possible increase of intensity within the chest; the distance at which that increase of intensity (if real) occurs from the part of the thoracic surface examined; and the relationship of pitch of the laryngeal and bronchophonic voices.

1st. In regard of conduction of laryngeal sound, theory would support the inference, that as the human voice is best propagated in air, the more the lungs were rarefied, the higher would their conducting power become; and, in accordance with this, it is certain that intense bronchophony is sometimes heard over highly emphysematous tissue. However, on the other hand, as the tracheal and bronchial walls themselves vibrate during speaking, any really solid ma-

(a) Skoda, of course, admits, that the bronchial walls, in the spot where consonance takes place, intensify the consonating tones of the air within them by their own vibration; but this is a very different thing from their taking part in the production of bronchophony by conducting the laryngeal voice.

(b) Curiously enough, the vocal *resonance* always ceases to be perceptible at a lower point of the scale than the vocal *fremitus:* this is another difference to add to numerous others distinguishing the properties of the two phenomena.

(a) The unison-note alone is distinct to ordinary ears: the consonating harmonics are so faint as to require the organ of a Costa for their detection.

(b) The case may be very different where vibrations are communicated from a body of one physical constitution to a consonating body of another class. Thus, where a tube takes up the vibrations of a solid disc, the consonating note of the tube may (by managing carefully the length of the vibrating column of air in the interior) be made incomparably more powerful than the original tone: the quality of such notes is exquisitely pure and full; and long ago Savart suggested the construction of a musical instrument on this principle, which, it seemed probable, would exceed in melody and power any of those in use. Civilised musicians have not profited by the philosopher's suggestion; yet the savages of some of the Pacific Islands, curiously enough, have hit upon rude contrivances illustrating the principle.

terial directly connecting a large bronchus with the surface of the chest, must conduct those vibrations forcibly; and, in accordance with this, we find that wherever solid fibrous structure is seated in the manner supposed, bronchophony of the most intense character is audible. But if the union of the solid material with the chest-wall be imperfect, if there be any interruption at the planes of union of the conducting materials, the acoustic conditions are completely changed, inasmuch as interruption at the union of media of different densities most deeply impairs the conducting faculty of the series. Here is one clue to the differences in vocal resonance, observed in cases where the physical conditions appear, on superficial view, identical; hence, too, we have no fair reason to expect that, in all samples of the variable semi-solid states comprised under the title of "hepatisation," conducting power should be affected in a uniform manner, and experiment shows that it actually is not. Experiment, in truth, alone can teach in each instance what the force of conduction really is in the various complicated conditions of physical change in the lungs.

2ndly. It is indubitable, that the bronchophonic voice is sometimes louder than that transmitted through the stethoscope directly from the larynx. The extreme rarity of this occurrence does not affect its reality; and hence, some explanation must be found for the increase of intensity within the thorax. We have seen the objections to Skoda's hypothesis of consonance. Now, there is another way in which the intensity of sounds may be augmented at a greater or less distance from their place of production—by reflection, and by reflections brought to a focus, or *echo*. But are the conditions of reflection fulfilled in the hepatized lung? It would appear so; for the tubes along which the voice is transmitted from the larynx are surrounded by semi-solid material, proper (when compared with healthy tissue) to reflect and concentrate the sound; while the air-cells and minute bronchi are closed to a variable distance, and prevent its divergence. The tubes resemble so many speaking-trumpets, and, just as in these instruments, the augmentation of sound is produced by reflection from their quivering walls; as this reflection tends to propagate vibrations (otherwise divergent) in the same direction, increased intensity of sound must be the result. And, further, if the reflected vibrations chance to be brought to a focus within a large tube, then *echo* will occur; and, as under ordinary circumstances, the echo may be materially louder than the original sound. But, it may be inquired, how, upon this theory, is the temporary disappearance of bronchophony, already referred to as a possible, though very rare occurrence, explicable? It is conceivable, that where such suspension occurs, this may sometimes depend on the deadening influence of accumulated fluid in the tubes. (a) It may also be sometimes traced to accidental pressure of a main tube by some extraneous body, which, from movements of the trunk, the act of coughing, &c., presses much or little, or not at all, upon that tube. (b) It seems extremely probable that, under the latter circumstances, bronchophony would, (I have not, however, verified this conjecture,) be heard at some point of the chest nearer the bifurcation of the trachea. Again, it is possible that certain changes of posture, altering the relationship of the reflecting surfaces, might interfere with the production of echo, by preventing the reflected sounds from coming to their usual focus. Besides, the position of the auscultator in respect of the focal point, might prevent him from hearing an echo really existing.(c) The force of the echo will also rise, the smoother the bronchial walls, and the larger the tubes in which it occurs. And numerous other circumstances may be conceived, but scarcely proved, to affect the phenomenon. Among these, the composition of the gases within the bronchi may, for aught that is known, hold an important place: hydrogen has been proved to deaden sound greatly; the effect of carbonic acid, mixed with other gases and aqueous vapour can only be ascertained from experiment.

Thirdly: As concerns the distance from the point of auscultation at which the reinforcement of sound within the thorax occurs: the further away, the less of the resonance will reach the surface; the amount, however, will be modified by the conducting property of the interposed media.

A little consideration will show that these three conditions of bronchophony,—conduction of laryngeal sound, increased intensity of this within the thorax, and proximity of site of the increase,—may or may not be directly as each other; one may be in a state favourable to, the rest unfavourable to, the formation of bronchophony. Hence the variable state of the sign in different cases of the same disease; and hence an additional clue, for example, to the inconstancy of bronchophony in pleuritic effusion.

Fourthly: The relationship of pitch of the bronchophonic and laryngeal voices seems the most difficult part of the subject,—difficult, at least, in those cases where a distinct difference can be detected in the pitch of the two. The consideration of this point is reserved for another occasion.

(a) The effect of carpeting or woollen cloth of any kind, in deadening the sound of music in an apartment is well known. The intermixture of air and solid fibres in the carpets, through which the sound has to pass, deadens the echo between the ceiling and floor, by which the original sound is swelled."—Herschel, art. "Sound," *Encyc. Metrop.* Aerated mucus and sanguineous serum in the bronchi would have the same effect on vocal echo in those tubes, as the carpeting under the circumstances referred to above.

(b) This cause is suggested from actual observation.

(c) The existing theory of echoes generally is inadequate to explain many of their phenomena. There is (or was) a ruined fortress near Louvain well illustrating this. Here, if a person sings, he only hears his own voice, without any repetition; those who stand at some distance hear the echo, but not the voice,—and they hear the echo with surprising variations,—sometimes louder, sometimes softer,—now near, now distant.—*Burrowes's Cyclop., Art. "Acoustics."*

DUMBNESS AFTER TYPHUS FEVER.

By WILLIAM FOLEY, M.D., M.R.C.S.

In the *Dublin Medical Press*, September 9, 1840, I published the particulars of an extraordinary "Case of Dumbness succeeding Typhus Fever," that at the time, and for a considerable period subsequently, excited a good deal of attention. It was copied into the *Medical Times* in the same month, and many of the continental journals.

The case was published not for any information it was calculated to convey, but as a question to physiologists and pathologists, What was the cause of dumbness; upon what lesion did it depend?

I am not aware that any explanation of the strange phenomenon has been given or attempted.

On looking to the report published in the *Medical Press*, I find it concludes with the following sentence:—

"I will not lose sight of this interesting case; and if the attempts to restore the lost faculty be successful, I will communicate all new particulars."

It is needless to go into the minutiæ of treatment, or to state the lively interest with which I watched its progress; suffice it to say, that years rolled on without the slightest improvement; so hopeless had it become, that I had quite forgotten it, until my attention was directed to it a short time since by a distinguished and philanthropic member of the Profession in Dublin, to whom I communicated all the particulars, and in whose able hands I hope soon to see a brilliant use made of it, that will throw an interesting light on pathological medicine.

During recent inquiries made about the case, I find that the patient continued completely dumb for the space of eight years, after which he and every member of his family were seized with typhus fever. Towards the termination of the disease he was observed to articulate one or two short words at different times. As convalescence progressed, pains were taken to teach him a few more, and by very slow degrees indeed, he was gradually brought on, so that now, at the end of three years, he can speak very distinctly, but at times so rapidly as to cause him great embarrassment.

The intensity of the disease must have been much less in the last attack than the former, as in the first he was quite unconscious nearly from the commencement; while in the latter, he has stated to me, that he never lost his recollection.

He has a perfect memory of every circumstance since his fever in 1839, was well aware of the privation under which he laboured, and therefore shunned intercourse with all except members of his own family. He understood very well the jeers and observations made by those thoughtless young persons among whom he was often obliged to be; galling as they were to his feelings, he had no way to defend himself, and could not convey that he comprehended every word as well as any of them.

I questioned him on different occurrences that took place since he had been my patient in 1839, and found that his

memory on, and acquaintance with, them was quite accurate; so that I have no doubt of the correctness of his comprehension during the eight years of his dumbness.

He told me, that since the original disease he felt a "weakness" in the right side of his body that never prevented his power of moving, but yet made him feel "uncomfortable;" that, as the power of speech returned, the "weakness" was diminishing, so that now he scarcely feels it.

I stated in the original Report, that he exhibited, during the fever, a very severe and well-marked paralysis of the right side, including every part from the eye to the toes; that on the nineteenth day it had nearly disappeared, and he was soon after able "to run about."

There seems to be no doubt that the leading feature was meningeal engorgement in the head, at all events, and probably continued into the spinal canal. I think it probable that striæ of that congestion remained at the base of the skull, compressing some of the filaments composing the roots of the glosso-pharyngeal portion of the eighth nerve; as also of the ninth on the same side.

That the organs of voice were not implicated, seems clear from the fact, that he could hum musical airs accurately and distinctly; his father often told me, during the first two or three years of his dumbness that "he could turn his tunes as well as ever he did."

A few months ago, I met what might be called a case of "dumbness after typhus fever," but not correctly, in the person of a boy about eight years old. He was attacked with fever at about the age of four years; he became very deaf as the disease drew to a close, and, as convalescence progressed, it increased until it acquired that degree of intensity that he could not hear a piece of artillery discharged within a foot of him.

His general health improved rapidly; he soon became quite well and strong. He continued for a time to speak as he was accustomed before his sickness, when he wanted anything, but gradually and rather quickly forgot most of his words, so that he has been for over three years accounted a "dummy" by his neighbours. He occasionally, but rarely, speaks—single words, and generally, of one syllable, as milk, bread, egg, turf,—when he sees objects whose names were very familar to him when he enjoyed all his faculties, but cannot remember words enough to express an idea.

The lesion, as well as the organs in fault, are quite different in this case from the former. In the former, the organs of hearing were not in the slightest degree impeded; the apparatus of speech alone was obstructed. In this, the parts subservient to speech were quite free, but the auditory apparatus was entirely useless; the lesion producing which may, in all likelihood, be meningeal congestion compressing the "portio-mollis" of both seventh nerves. It has been observed of him, that, as he became unable to communicate his feelings, he has grown exceedingly mischievous.

A very remarkable circumstance in the former case is, that dumbness caused by typhus fever, and of eight years' continuance, was cured by another attack of the same disease. If the subject of the second case should be equally fortunate, it would be a curious coincidence. If, in the meantime, the child would be taught to spell and read as deaf and dumb children are, I have no doubt, that instead of answering by signs as they do, he could reply in speech, as what appears to be dumbness in him, is simply unaccustomedness to conventional terms, the organs of speech retaining the power to utter them, if the memory were only stored with a supply.

Kilrush.

GANGRENOUS THECAL INFLAMMATION OF THE HAND FROM A BITE.

By ALFRED CARR, M.D.

John Gallagher, a night-watchman, applied to me with a contused wound of the finger. (The end had been bitten off in the course of a drunken brawl by his adversary, during the night of August 8, 1851). The wound was dressed, and he was directed to come again the following morning, when I proposed to amputate the finger immediately below the seat of injury. Not wishing to undergo the operation, he did not return, but placed himself under the care of an empiric. I lost sight of my patient until November 15. He had then been, for the last six weeks, an outpatient at the Manchester Royal Infirmary; but, being unable to leave his bed to attend at the Infirmary, he sent for me, and promised, if I would again take charge of him, to submit to any operation it might be deemed necessary to perform. I found him suffering from suppurative fever, with a feeble, quick, and irregular pulse; the hand bent at nearly a right angle with the wrist, and much swollen. Pressure being made upon the wrist, which was very tender, a small quantity of unhealthy pus escaped from a fistulous opening, which existed opposite the digital extremity of the fourth metacarpal bone, and from which hung a portion of diseased tendon; a probe passed readily from this opening along the course of the deep flexor tendons and for some distance beneath the annular ligament at the wrist; there had been a copious discharge of matter from this opening for many weeks, which, however, had entirely ceased for several days; he had not slept soundly for the last three weeks in consequence of the pain in the hand and wrist; bowels constipated.

Ordered a brisk purgative immediately, and when this had operated freely a sedative, consisting of 3ss. of Battley's sedative solution of opium, and a linseed poultice applied to the hand.

Nov. 16.—The bowels have been freely relieved, and the opiate occasioned a sound night's rest; there is a free discharge of healthy matter from the wound in the hand; feels much relieved and more free from pain than for some time past. The opiate to be repeated at bed-time.

17th.—With the assistance of my friends Messrs. Hunt and Melland, chloroform was administered, and, a grooved director being introduced, an incision was made throughout the whole extent of the sinus, dividing the arteries forming the palmar arch and a portion of the annular ligament, and the diseased portions of fascia and tendon dissected away; about half an hour was fruitlessly spent in endeavouring to secure the divided vessels, which, owing to the diseased state of the parts, it was found impossible to do, and the patient becoming very much exhausted, it was decided to cut down upon and secure the brachial artery; this was immediately done, and the hæmorrhage arrested; no sutures were applied to the hand, which was simply dressed with lint and poultice. Three doses of laudanum, amounting, in the whole, to 3iij ss., were given to the patient, by Mr. Hunt, during the latter part of the operation, with the most beneficial result, and without producing any other signs of narcotism than a contracted pupil.

8 p.m.—Has not slept since the operation; there has been a slight hæmorrhage from a small artery, which had been divided in the incision for securing the brachial artery; slight pressure arrested this immediately; there has been no hæmorrhage from the hand.

18th.—Has passed a good night, without pain or restlessness.

22nd.—Upon removing the poultice, about half an ounce of blood escaped in the direction of the wounded palmar artery; the hand has resumed its natural position, and both hand and wrist have nearly resumed their natural size; the patient can bear moderate pressure at the wrist without pain; pulsation can be distinctly felt in the radial artery; the wound in the hand is rapidly closing up, a small portion only of sloughing fascia remaining near the wrist.

23rd.—The remaining portion of slough was removed this morning. Upon making firm pressure over the wrist, a small quantity of pus escaped from under the undivided portion of the annular ligament, and a probe passed easily for about an inch from the deepest part of the wound into the wrist; a bandage was applied firmly round the wrist, and the hand placed in a more dependent position, to allow of the free escape of pus. Ordered a mild aperient, the bowels not having been relieved since the operation.

25th.—The pressure at the wrist appearing to do more harm than good, was discontinued.

28th.—A fluctuating tumour having gradually formed above the wrist, a free incision was made, commencing about three inches above, and extending to the annular ligament within an inch of the former incision, it being considered desirable to save as much of the annular ligament as possible undivided. A copious discharge of pus followed the knife, and the pulse, which had, before the operation, been 120, shortly sank under the influence of the operation, and about 30 drops of laudanum to 81.

Dec. 5th.—No discharge of matter from any part of the wound; the incision in the hand has nearly closed up.

24th.—Both wounds completely healed, and the patient is gradually recovering the use of the thumb and uninjured fingers.

Rusholme, Manchester.

ON THE EMPLOYMENT OF UREA AS A DIURETIC.

By T. H. TANNER, M.D.,

Licentiate of the Royal College of Physicians, Physician to the Hospital for Women, etc.

It has been frequently remarked, that of all classes of medicines in the Materia Medica, none are more uncertain in their operation, or less to be depended upon, than diuretics,—a remark the truth of which can be corroborated by most medical practitioners. Unfortunately, also, their unequal mode of action is seldom more painfully felt than when the influence of these remedies is especially desired to promote the absorption of dropsical effusions,—the most legitimate object, perhaps, for which they can be used. It was during the treatment of a tedious case of dropsy, dependent upon heart disease, that, after a trial of most of the agents known to possess diuretic properties, I was led to employ urea, the principle which it is doubtless the chief function of the kidneys to separate from the blood, forming, as it does, nearly one-half of the whole solid constituents of the urine.

Urea was first obtained pure by Dr. Prout, in 1817; its artificial production from cyanic acid and ammonia was discovered by Wöhler, and is interesting as being the first example of an organic product artificially formed. Dr. Prout thus describes the method of procuring it. "Fresh urine is to be carefully evaporated to the consistence of a syrup, and to this, when quite cold, pure concentrated nitric acid is to be added by degrees, till the whole becomes a dark-coloured crystallised mass, which is to be slightly washed with cold water, and suffered to drain. To this mass is then to be slowly added a pretty strong solution of the subcarbonate of potash or soda, till the whole becomes neutral; and the solution thus formed is to be carefully concentrated by evaporation, and set aside, in order that the nitre formed may crystallise, and thus be separated. To the impure solution of urea left, animal charcoal is to be added in such quantity as to absorb the whole fluid and form a thin paste, which may be suffered to lie for a few hours. Cold water is to be added to this paste, which separates the urea, and the colourless solution thus obtained is to be slowly evaporated to dryness at a low temperature. The resulting mass is then to be boiled in strong alcohol, which takes up the urea, and leaves the remainder of the nitre and most of the other saline substances behind; and from this state of solution in alcohol the urea may be readily obtained crystallised and pure, though it is generally necessary to repeat the process of crystallisation from the alcohol two or three times."—Medico-Chirurgical Transactions, vol. viii., p. 528.

Another plan has been proposed by Dr. Gregory, for obtaining this agent, according to which the concentrated urine is to be saturated by oxalic acid, crystals of oxalate of urea being produced; these, dissolved in water, decoloured by animal charcoal, and decomposed by digestion with carbonate of lime, yield a solution from which colourless crystals of urea may be procured.

The easiest and cheapest way of preparing it, however, is found to be artificially from cyanate of ammonia, by the process recommended by Liebig. Twenty-eight parts of dried ferrocyanide of potassium and fourteen of peroxide of manganese are mixed in powder, and calcined upon an iron plate, heated to dull redness; the mixture takes fire, but is gradually extinguished, and must be stirred while cooling, to prevent agglutination. The cold mass is then powdered, and digested in cold water, which dissolves the cyanate of potash; this solution is filtered off, and set aside; the remaining powder is then washed with a second portion of cold water, and again filtered, and in this liquid is now dissolved 20·5 parts of sulphate of ammonia, and the solution added to the first filtered solution of the cyanate. A large quantity of sulphate of potash is deposited, which is strained off, and the filtered liquid now containing, with some sulphate of potash, all the cyanate of ammonia, is evaporated to dryness, during which process the cyanate of ammonia is transformed into urea. The dry mass is digested in alcohol, which only dissolves the urea, and yields it pure on evaporation.—Liebig, Annalen der Pharm., xxxviii. 108.

In whatever way urea is procured, it appears in the form of delicate silvery acicular crystals, which are seen by the microscope as four-sided prisms; they are colourless when pure, free from odour, and generally resembling nitre in appearance, possessing also a similar cooling saline taste. The crystals are soluble in their own weight of cold water, and in every proportion of hot, their solution being neither acid nor alkaline. The composition of urea is $C^2\ O^2\ H^4\ N^2$.

The preparation which I first employed was obtained by Mr. Garden, of Oxford-street, from urine; Mr. Cocksedge, chemist, of New Oxford-street, has since procured some from the same source, and has prepared some of the prescriptions in which I have ordered it. It is, of course, unnecessary to say, that whether this agent be procured from urine, or prepared artificially, it ought to possess the same properties, and consequently be capable of producing the same effects. I must, however, remark, that I prefer the preparation obtained from the urine, my reason for this preference being, that in trying some experiments upon a dog, I found that the urea obtained from the cyanate of ammonia was less efficacious. At the same time, I would mention, that as my experiments were very roughly carried out, the difference may have been due to other unobserved causes. It was unnecessary to resort to experiment to prove that urea, medicinally administered, does not exert any deleterious or poisonous agency upon the system, because this had already been done by Dr. Todd. This gentleman injected half a drachm of urea into the vein of a dog, the only effect produced being an excessive secretion of urine, so that the place where the animal was kept was literally flooded in an hour or two by the frequency and quantity of his micturition. In the human subject a copious diuresis has been the only effect produced; in none of the cases in which I have employed it has it given rise to any unpleasant symptoms whatever. The ordinary dose, on first being used, is ten grains every six hours, dissolved in water flavoured with syrup; as its effects decrease, the dose may be augmented to a scruple or more. At the same time, its action should be aided, as that of all diuretics should be, by the free administration of diluents, as well as by keeping the skin moderately cool. From observation of the mode in which medicines are prescribed in the present day, I fear that by far too little attention is paid to those collateral circumstances which assist the action of all remedies, and which in certain cases, if unattended to, render our efforts useless, effects being produced the opposite to those intended. Boerhaave, the great medical luminary of the seventeenth century, first pointed out that many diuretics may be so administered as to prove sudorifics; and Dr. William Alexander taught that "the salt of tartar and of nitre, though among the most powerful diuretics, when taken with large quantities of warm liquids, if the body be well covered, prove excellent sudorifics, and do not increase the quantity of urine."—Experimental Essays: Lond. 1770. p. 155.

None deny the truth of these observations: I would only intimate that they are not sufficiently attended to.

It would be worse than useless to occupy the space of this Journal by a recital of the few cases in which I have employed this agent as a diuretic. It may suffice to say, that, in the first instance, and the one in which I more particularly noted its effects, the quantity of urine secreted in the twenty-four hours previous to its administration was only fourteen ounces (high-coloured, acid, sp. g. 1018), whereas, in the succeeding twenty-four hours, during which three doses of ten grains each were administered, the secretion amounted to forty-four ounces (pale, acid, sp. g. 1013). The remedy was continued for the ensuing nine days, in doses of ten grains every six hours, during which period the urine varied in quantity from forty-nine to thirty-eight ounces. At the end of this time it was discontinued, as the dropsy had been temporarily removed; and, on again having recourse to it three weeks subsequently, its effects were as satisfactory.

In conclusion, I would remark, that urea has been prescribed before, especially by some French physicians. The object of these remarks, therefore, has been, not to introduce a new remedy, but to bring forward one which does not appear to have been sufficiently appreciated.

SUCCESSFUL CASE OF LIGATURE BOTH OF EXTERNAL ILIAC AND SUPERFICIAL FEMORAL ARTERY

ON THE SAME SUBJECT.

By HENRY SMITH, Esq.,

Surgeon to the Westminster General Dispensary.

In the *Medical Times* for October, 1850, I published the case of Thomas Whitton, aged 37, upon whom I had recently performed the operation of tying the external iliac artery on the left side. The disease for which I tied the vessel was an aneurism high up in the thigh. By reference to the published account, it will be seen, that the patient rapidly recovered from this severe proceeding without a single bad symptom; and he returned to his occupation.—which, unfortunately for him, was one calling for a considerable share of muscular exertion on his part. A few months after he had returned to his work, a hernial protrusion appeared in the situation of the wound in the abdominal parietes, for which a truss was applied, and has been worn since; with the exception of this inconvenience, the man suffered in no way from the effects of the operation.

During the past year, he called my attention, on more than one occasion, to the circumstance of his suffering from muscular pains in the limb of the opposite side; and, on the 18th of January, 1852, he came to me, complaining of swelling of the foot, and numbness in the lower part of the right leg. On observing this, I at once suspected that there was an aneurism, and, on examining the popliteal space, I discovered a large pulsating tumour, which presented all the features of that disease. The knee-joint was enlarged and swollen, and there can be no doubt that the aneurism had existed in this situation for some length of time, or that it had recently formed, and very rapidly attained its present size. The patient himself had only observed the symptoms which led him to come to me the day previously. I at once advised him to go home and lie quietly in bed for a day or two, and take some opening medicine, to prepare him for the operation which I proposed to perform.

On the 21st, I placed a ligature upon the superficial femoral artery. I commenced the incision about three and a half inches below Poupart's ligament, carrying it downwards to the extent of about three inches; in this were included the superficial tissues. I next divided the fascia lata, and came upon some muscular fibres, which at first I thought were those of the sartorius, but, on closer examination, it was discovered that they belonged to the adductor longus. Consequently, it was necessary to get a little more outwards, when the edge of the first-named muscle was exposed, and the artery was readily felt, lying deeply down in the angle formed by the two muscles. Its sheath was opened with care to the extent of an eighth of an inch, and the aneurism-needle was cautiously carried around the vessel from the inner side, and the artery was tied. The pulsation in the aneurismal tumour immediately ceased. In the evening the patient was cheerful, and feeling comfortable; pulse 88; toes cold.

22nd.—Pulse 88; some pain in the limb.

24th.—Has had a good deal of pain down the limb, and sensations of pins and needles in his foot and toes. I this day took off the dressings, and found the wound looking remarkably well; pulse 90; bowels open; no fever.

February 2.—Wound all united except at that point where the ligature hangs out, and one other point below where one of the sutures was inserted; the aneurismal tumour is much diminished in size.

10th.—Ligature came away; the patient was ordered to remain in bed for a week, at the end of which time he got up, and at the end of the month he was enabled to walk out.

I have since carefully examined this patient, and also have submitted him to the inspection of the Fellows of the London Medical Society. There is a firm cicatrix in the situation where the external iliac artery was tied, and no hernial protrusion through the deficiency in the abdominal wall; the arterial pulsation can be plainly distinguished just below Poupart's ligament, and be felt some short distance down the thigh. I cannot, however, make out any pulsation in the popliteal artery, or in the anterior or posterior tibial. On the right side the common femoral can be distinguished by the pulsation; but, as in the other extremity, no impulse can be detected in the several arterial trunks, nor as yet have I been enabled to find out unusual pulsation in any part which would indicate any particular enlargement of the branches of the chief arteries. I could distinguish only a slight, hard, round substance in the upper portion of the right popliteal space, the remains of the aneurism. The patient enjoys free use of his limbs; the temperature in each appears to be natural, but he occasionally feels some muscular pains in the limb last operated upon.

Ever since John Hunter first performed his operation of tying the superficial femoral artery, in 1785, a proceeding, indeed, which was the indication of a great and successful era in the history of surgery, this vessel has been so often tied with success, that the publication of such a case would now-a-days be, perhaps, deemed superfluous, unless there was some peculiar interest connected with it; and, in fact, now that another revolution is being brought about in reference to the treatment of some forms of aneurism, an unsuccessful case would, perhaps, be considered of more practical interest, as the causes of failure must be thoroughly inquired into and appreciated by those who are endeavouring to establish a new method of treatment, for their success in convincing the Profession will depend upon their pointing out the several dangers which follow upon the ligature of a large arterial trunk, and showing that, by another mode of proceeding, all or most of these dangers may be avoided. However, it is more pleasing for me to be enabled to bring before the Profession, not only a case which has turned out to be successful, but one which has connected with it an unusual amount of interest, in consequence of the subject of the operation having previously undergone the more severe operation of ligature of the external iliac artery. There have been, I believe, a few cases on record in which either artery of the thigh has been successfully tied on the same individual, and—going away from this region—we are all familiar with the remarkable instance of ligature of either common carotid vessel by the celebrated American surgeon, Mussey; but I have no recollection of meeting with the recital of a case in which, like this, the external iliac on one side, and the superficial femoral on the other, have been ligatured with success; and, therefore, I may perhaps not be considered presumptuous in hoping that the record of this case may be looked upon with special interest by those whose delight it is to view the success of surgery. There cannot, moreover, be a case on record which more completely attests the great triumph of the doctrine which our immortal John Hunter first promulgated and first successfully carried out; and for this reason alone I look upon this case as one of paramount interest. Independent of this consideration, too, it will not be the less interesting, as marking the progress of surgery, when we call to mind, that it is not a hundred years ago that Burchell first tied the femoral artery in the Manchester Infirmary.

I have already been asked why I did not apply compression instead of tying the superficial femoral artery; and to that question I answered as now, that the patient recovered so rapidly, and without the least unfavourable symptom, from the more formidable procedure of tying the external iliac, and he was so good a subject, from his courage, patience, and physical conformation, for an operation, that we had the strongest reason to suppose that he would do equally well after the less serious measure; and the result shows that I was not deceived in my anticipations. Still, if the patient himself had determined upon it, I should have employed compression; and on any other occasion shall always submit this method of treatment to the consideration of the patient.

I have stated, that a few months after the external iliac had been tied, and the patient had returned to his work, there was a hernial protrusion through the weakened abdominal wall. For this I applied a truss. Since the man had been confined to the horizontal posture, however, this protrusion disappeared, and even when he takes his truss off there is no protrusion; but I have desired him to wear it, as he finds relief, and it may obviate danger.

In reference to the operative process, there is one point of interest. It will be found, that after making my incision through the fascia lata, I came upon some muscular fibres, which at first I took for those of the sartorius; but on strict examination they were discovered to be the edge of the adductor. This confounding of the two muscles may, I believe, easily occur, but is as easily rectified by attending to the course of the vessel, which, however, is situate at this

point much more deeply than some might imagine. I had a much greater difficulty in carrying the aneurism needle around the artery here than in the iliac fossa, for the vein was much more in the way than in the case of the iliac artery, and I was much more fearful of wounding it; and, indeed, it would have been much more easy to do so.

In conclusion I have to state, that I was as ably assisted in the second operation as in the first by Mr. Fergusson, and by Messrs. Nunn, Gay, and Borlase Childs.

13, Caroline-street, Bedford-street.

THE LONDON PRACTICE OF MEDICINE AND SURGERY.

ST. MARY'S HOSPITAL.

By HARVEY LUDLOW, Esq., M.R.C.S.,
Late House Surgeon at St. Bartholomew's.

LITHOTOMY.

Much as the manner of operating for stone has been improved, and simple as it has now become, there are contingent circumstances which must ever make it formidable, and complications perplexing to the ablest surgeons continually arise, with which, therefore, we should be acquainted and ready to grapple. The cases here briefly reported, are intended to illustrate some of the difficulties which beset the operator, and to point out the means now practised by eminent surgeons for overcoming them.

Case 1.—Robert Long, aged 11, was admitted into St. Mary's Hospital, April 4, under the care of Mr. Coulson.

He had suffered since birth from incontinence of urine, a symptom which became more distressing during the six months preceding his admission. The child manifested no signs of pain, did not pull the prepuce; there was a small quantity of blood and mucus mingled with the urine; but except the frequency of micturition, and occasionally the sudden stoppage of the water, no unequivocal symptom of calculus was present.

The parents stated, that some time ago he had been tormented with pain, and was continually pulling the prepuce; but this symptom passed away, and for a few weeks before admission he had apparently not suffered at all. On being sounded, a stone was detected, evidently not resting on the base of the bladder, but lodged in the fundus, closely adjacent to the anterior wall, for it was only when the handle of the sound was depressed and its point brought forward, that it could be struck.

On the 7th Mr. Coulson proceeded to operate. The bladder was penetrated by a beaked knife, but when the operator's finger was introduced, the stone could not immediately be felt, and being situated quite anteriorly, and, in all probability, adherent to the front wall of the bladder, some difficulty would have been experienced in extracting it, had not the pelvis of the child been raised before the introduction of the forceps. By adopting this measure the stone was readily seized, and the operation completed within a minute. There was scarcely any blood lost. The subsequent progress of the patient was good; he was able, in a fortnight, to void his urine by the natural passage, and the cicatrisation of the wound is now fast advancing.

Adherence of a calculus to some part of the vesical parietes, is in children not infrequent, and may prove a source of deception in the diagnosis, or of embarrassment in the operation. When a stone previously loose becomes adherent, all or most of the symptoms more or less decisive of its presence vanish; as the stone no longer falls against the neck of the bladder, the stream of urine is not impeded, nor is there any pain felt at the extremity of the penis; the bladder, indeed, hypertrophied, morbidly irritable, and still stimulated by the presence of unhealthy urine, discharges its contents with unnatural frequency, and blood and mucus will, in all probability, be mingled therewith; but the more definite and pointed indications of calculus have departed, and a superficial observer might be easily deluded into the notion, that his young patient was suffering from vesical disease, unconnected with the presence of vesical calculus. I am acquainted with an instance in which a boy in a large school suffered for three or four years from incontinence of urine, and inability to command his motions, but was not much tormented with pain, and in whom, though he was sounded on two or three occasions, no calculus could be detected. The lad was at length brought to London to consult Mr. Lloyd, and that gentleman failed, on the first examination, to detect a stone. Subsequently, however, having placed the boy under the influence of chloroform, (a proceeding which had not been previously practised,) he succeeded in finding one which he afterwards removed by operation.

Incontinence of urine, thus long established, does not always disappear with its source. Whether from the inveteracy of habit, the persistence of an unhealthy state of the urine, or the slowly departing irritability of the bladder itself, it may continue; and, influenced by such causes, either acting singly, or in combination, this most distressing and unpleasant affection is not invariably removed with the calculus that originated its existence. With reference to this point, the condition of the boy on whom Mr. Lloyd operated is scarcely meliorated since the extraction of the stone.

There are thus two sources of deception: one in which absence of decisive symptoms causes the existence of stone to be overlooked, and the case to be regarded as one merely of high vesical irritability; the other, in which a patient from whom stone has already been extracted, presents still persistence of symptoms, which previously indicated the true nature of his malady, and may lead the surgeon to search for another concretion, and thus perpetuate his own delusion, by heightening, through the introduction of sounds and other instruments, that morbid condition established by long irritation, and subsiding by slow degrees. Under the former of these circumstances, it will be absolutely necessary to sound the patient with care and diligence, and to repeat the proceeding until either a calculus is detected, or till unsuccessful explorations by various hands have rendered its presence improbable. It appears essential, however, that the patient should be narcotised by inhalation of chloroform before undergoing a search always more or less painful, and generally rendered useless by the cries and struggles of the child, unless the powers of this anæsthetic are brought to bear. Its administration saves much suffering, facilitates extremely the discovery of stone in children, and often enables the surgeon to accomplish at one trial that which he can only accomplish by several without it. Where, however, an operation has been performed already, perhaps at no distant date, it will be well, in the absence of decisive indications, to refrain from at once introducing instruments, which may sensibly augment the existing evil, and can scarcely do good, and to leave the patient to reap the advantage of that restoration which the powers of Nature and the march of time will in all probability sooner or later afford him.

Not only, however, may errors in diagnosis result from the adhesion of a calculus; it becomes, in addition, a source, and sometimes a serious source of difficulty in the operation adopted for its removal. In the case reported here, Mr. Coulson was fully prepared for the event, and had, prior to the operation, satisfied himself that the stone would not probably be found at the base of the bladder. Indeed, when the operator had passed his finger into the bladder, a second or two elapsed before he touched the stone, and it was then found lying close to the anterior wall, contiguous or connected to the mucous membrane. In consequence of the elevation of the pelvis, the calculus was removed without difficulty; but, had this precaution been neglected, or had the stone been small, and not easy to seize, the operation might have been much prolonged, and its last stages would undoubtedly have not been so readily executed. A complication of this nature occurred about the beginning of last March to Mr. Skey. That gentleman, on the same day, cut two children for stone. In the first case, the stone was caught and extracted without difficulty, and the operation was rapidly finished; but in the second, a small stone, resembling an almond in shape, happened to adhere closely to the front wall of the bladder, and as the urine had been discharged, the operator found it no easy matter to lay hold of it. This, however, he at length accomplished, with a pair of cross-blade dressing forceps. A child, on whom Mr. Wormald operated last year, had prolapsus ani in conjunction with calculus vesicæ, a condition brought on no doubt by the frequent and violent efforts at defecation which occurred whenever the irritable bladder expelled its urine; the consequence was, that the lower part of the bladder became dragged down by the protruded bowel, and a cul de sac was formed behind and below the vesical neck in which the stone was lodged. This being small, could just be felt by the end of the finger, but it was found impossible to depress sufficiently the blades of the forceps to grasp it. All these instruments passed beyond its point of rest. Elevation and concussion of the pelvis failed to stir it. At length Mr. Wormald passed his finger into the rectum, tilted up the pouch, and the stone within it, and then succeeded in seizing the latter at the neck of the bladder. Naturally, in very young children, the bladder is almost without what is termed by the French the *bas fond*. There is an absence of that descent, that broad, full pouch which rests on the rectum, and comprises the trigonum vesicæ in the adult. Perhaps it is owing to this disposition of parts, and also to the more complete emptying of the blad-

der effected by children, so that the vesical walls are brought in closer contact, that stone becomes occasionally adherent in these young subjects. Such a complication is, I believe, never, or most rarely, met with in individuals of advanced life, persons in whom the bladder is fully grown and shaped, and in whom, probably, the retained calculus possesses greater relative weight than in children.

During the last twelve months, Mr. Coulson has performed five operations for stone at St. Mary's Hospital, all on very young children. He observes, in his lately published work, (on Diseases of the Bladder and Prostate, page 307,) that "it is undeniable, that the disease is very frequent under the age of puberty, in ill-fed, badly-clothed children." However, it appears that, if the poor suffer in childhood, the wealthy are visited in advanced life; for Mr. Coulson remarks:—"Among those beyond the middle age, stone occurs more frequently in persons of sedentary habits than in those who lead an active life, and much more in those who indulge in luxurious living than in the temperate and abstemious."

Among the cases operated on at St. Mary's, one, a child of four years, three hours after the operation, suffered from hæmorrhage, which, however, was easily controlled, and the child recovered subsequently without an unpleasant symptom. All the other cases rapidly got well. Now, hæmorrhage from the wound after lithotomy, though unusual, is occasionally met with, and becomes, especially in children, an accident at once dangerous and formidable. It may arise from division of arteries, or division of veins. When the artery of the bulb is given off low down, and is large, or when the internal pudic terminates in the superficial perinæal, or in the artery of the bulb, the penis being supplied by an accessory vessel often as large as the pudic itself—a vessel which, from its close proximity to the prostate and membranous portion of the urethra, can scarcely escape division by the incisions requisite for the operation, when such irregularities of arterial distribution are present, the resulting hæmorrhage is in the highest degree alarming, and not unfrequently fatal. Accidents of this sort are, however, rare; but there is a kind of hæmorrhage of more frequent occurrence,—a venous hæmorrhage, which bursts out suddenly some hours, possibly even some days, after the operation. It is often difficult to check, and, if not checked, it kills the patient. Hæmorrhage of this description arises from a division of the prostatic venous plexus, whose component vessels may be large, and may extend further forwards than usual. The cut mouths of these vessels are in all probability at first closed by loose clots, which sooner or later get washed away, and blood escapes outwards through the wound, and inwards into the bladder. Two cases of this secondary hæmorrhage are related by Sir B. Brodie, one having occurred in his own practice, the other in that of Mr. Earle. In both instances seven or eight days had elapsed from the operation before its appearance. Sir B. Brodie and Mr. Coulson are inclined to regard this peculiar hæmorrhage as the result of the separation of a slough; but I have seen instances of extensive sloughing of the wound after lithotomy, in the greater part of its depth, and yet no hæmorrhage supervened; while, on the other hand, secondary bleeding happens in cases where no sloughing can be discovered. Whatever its source, it is not always easy to suppress; plugging with dry lint, or with lint steeped in the strong infusion of matico; turpentine, applied in accordance with the recommendation of Mr. Vincent; or the tinct. ferri. sesquichloridi have succeeded in staunching it, and will unquestionably often succeed; but it should never be forgotten, that though the external effusion may be prevented, yet blood may continue to escape internally into the bladder, and the patient become alarmingly weakened in consequence. Mr. Lawrence operated on a boy in whom hæmorrhage supervened, and persisted in spite of every application; it was at last commanded by the hourly exhibition of sulphate of quinine in large doses, and in similar instances the same remedy, whose powers of controlling passive hæmorrhage are certainly great, might be employed with similar success.

Lithotomy exemplifies, perhaps more strikingly than any other operation, the great advantages conferred on practical surgery by chloroform. Mr. Coulson observes, (p. 380,) that prostration after lithotomy has certainly been less common since the introduction of anæsthetics; and many other eminent hospital surgeons entertain the conviction, that not only are the patients benefitted by being relieved from pain during surgical operations, but that they are absolutely better afterwards, are less liable to die, and more rapidly restored to health, than they were previous to the discovery of anæsthetic agents. The fatality of lithotomy has, I am persuaded, greatly decreased during the last five years, especially as regards children. Formerly extreme terror, and other mental emotions occasionally brought on prostration, which proved fatal in a few hours, although all the circumstances connected with the operation had been favourable. Examples of such an occurrence are recorded by Mr. Travers in his work on Constitutional Irritation, and most surgeons of experience have witnessed them. Perhaps, therefore, it would be difficult to select an operation which, more forcibly than the operation for stone, demonstrates the unequivocal advantage of removing the body from the agitating influences of the mind.

SCIENTIFIC LECTURES.

TUESDAY, THURSDAY, AND SATURDAY, MAY 11, 13, AND 15.—ROYAL COLLEGE OF SURGEONS. *Subject*:—Professor PAGET, "On Malignant Tumours."

LIST OF SCIENTIFIC MEETINGS FOR THE WEEK.

This Evening, May	8.	ROYAL INSTITUTION. *Subject*:—Prof. FARADAY, "On Points Connected with the Non-Metallic Elements." Three o'Clock.
——	——	MEDICAL SOCIETY OF LONDON. *Subject*:—J. F. BROWN, Esq., "On the Treatment of Ovarian Dropsy by a New Method of Operation." Eight o'Clock.
Monday,	May 10.	ROYAL INSTITUTION. *Subject*:—J. CONOLLY, M.D., "On Insanity." Four o'Clock.
Tuesday,	May 11.	ROYAL INSTITUTION. *Subject*: — E. LANKESTER, M.D., "On the Physiology of Plants." Three o'Clock.
——	——	ROYAL MEDICAL AND CHIRURGICAL SOCIETY. Half-past Eight o'Clock.
Wednesday,	May 12.	ROYAL INSTITUTION. *Subject*:—J. CONOLLY, M.D., "On Insanity." Four o'Clock.
——	——	HUNTERIAN SOCIETY. *Meeting of Council.* Half-past Eight o'Clock.
Thursday,	May 13.	ROYAL INSTITUTION. *Subject*: — R. WESTMACOTT, Esq., R.A., "On the History and Practice of Sculpture." Three o'Clock.
Friday,	May 15.	ROYAL INSTITUTION. — *Subject*: — REV. E. SIDNEY, "On the Rise of the Sap in the Spring." Half-past Eight o'Clock.
Saturday,	May 16.	ROYAL INSTITUTION *Subject*:—Prof. FARADAY, "On Points connected with the Non-Metallic Elements." Three o'Clock.
——	——	MEDICAL SOCIETY OF LONDON *Subject*:—Dr. W. V. PETTIGREW, "On Burns and their Treatment." Eight o'Clock.

Medical Times & Gazette.

SATURDAY, MAY 8.

THE VICE OF SPECIAL HOSPITALS.

IT must certainly strike every one as a singular contradiction, that, while charity sermons are preached on behalf of distressed medical charities, and the most piteous of appeals are made, through the advertising columns of the *Times*, for support to hospitals in the last stage of syncope, new schemes for little pocket-sized editions of similar institutions, but mostly of a special character, are continually obtruding themselves, and every art used, legitimate and illegitimate, to attract the attention of the charitable.

Thus, an entire floor of the Charing-cross Hospital is silent and deserted; Westminster Hospital cannot afford to make up half its number of beds; and the University and St. Mary's Hospitals have many vacant wards. Now with all this poverty of existing institutions confessed before the world, we find two new and insignificant institutions, the Cancer and Fistula Hospitals, springing up, and demanding a share of those contributions which are already drained so dry. If the purse of the charitable public was so deep that, like the sea, we might dip again and again into it without appreciably diminishing its supply, there then might be one objection the less to multiplying demands upon it; but, when it is so well known, that those who give form a comparatively small class dis-

tinct from the community at large, it becomes the part of the Journalist to urge that those funds shall not be wasted, as they undoubtedly are, by the multiplication of small hospitals.

It must be very evident, that one large hospital, containing, say, 300 beds, all under one roof, and worked by one staff, can be maintained much more economically than half a dozen of 50 beds each, every one having its own building, secretary, matron, etc. etc. But, supposing the case to be as it really is—that there is no need of erecting a building to contain this number of beds; that they really exist in institutions fully appointed and at work; how clearly it is seen that these new schemes are unjustifiable attempts upon the pockets of the charitable.

It might be answered, that it is not expedient to receive certain special diseases at general hospitals. There are some maladies, perhaps, that it is as well not to mix with others. Phthisis, from the uniform temperature its treatment requires—fevers, and infectious diseases, might call for special arrangements. But we are not so certain that even these require distinct buildings; and the determination of the Governors of the Fever Hospital to open their wards to other diseases strengthens us in the doubt. Hospitals for sick children, and such as have lately been proposed for incurables, are not objectionable; but what on earth is there in the nature of either cancer or fistula to necessitate separate establishments,—unless it be the private ends of those who promote them?

If it is thought expedient for the further investigation of the former fatal disease, that it be made a special study, which we do not deny, why not open a ward for its treatment in some existing hospital, instead of spending money uselessly in bricks and mortar? The 5000*l.* collected for the building fund of the Fistula Hospital, or St. Mark's, as its promoters, with a Yankee delicacy, intend to call it, would furnish Charing-cross and the University Hospitals with double the number of beds they now possess, and leave a sufficient surplus for their working expenses. While the 3000*l.* now probably thrown away in creating a separate establishment for cancer, would set up the Westminster Hospital, and afford room for many more patients than Dr. Marsden contemplates to receive.

In Vienna, where the best hospital accommodation in the world is to be found, they manage things differently. The Allgemeine Krankenhaus, or common hospital of that city, contains three thousand beds; and here different wards are appropriated to different diseases. The modern principle of division of labour, which is a necessity of the age, and which we by no means wish to oppose, is carried out to its full extent; but our English error of special hospitals is avoided. The student can pass from one ward to another; have under his eye at once all the maladies which afflict humanity; mark their bearings upon each other; and easily trace the general unity of disease. Great and effective medical schools can alone ariseout of such consolidated institutions.

The vice of our special hospitals, stuck in every conceivable corner of the vast desert of London, is made the more evident by contrast with the example cited. Its tendency is to destroy medical schools;—to drain and starve the great hospitals, both of money and instructive cases; and if it goes on, and every disease to have a widely separated location and charge for study, a Hansom cab and a long purse will be required by the student to perfect his education.

Let us repeat, that we by no means wish to oppose specialties. Medicine is grown too wide a science for any individual mind to grasp. It is as indispensable for our surgeons and physicians to be rendered facile of hand, and keen of diagnosis, by the study of special diseases, as it is to have division of labour in our manufacturing system. But we do object to the division of disease brought about by special hospitals, and, as we have shown, the consequent destruction of our medical schools, and the frittering away of the funds of the charitable. Ourselves, in common with all disinterested medical men, must look with suspicion upon the motives of the projectors of schemes having such a tendency; and we shall not fail henceforth to combat any attempt to create further mischief in this direction.

UNIVERSITY COLLEGE.

The announcement we made, a fortnight ago, that Mr. Maclise had been appointed Assistant-Surgeon to University College Hospital, proves to have been incorrect. The appointment of Mr. Statham, of whom we previously knew little or nothing, has taken us by surprise; and as it has, moreover, been brought prominently before the Profession, we shall place before our readers a correct version of the case. It is no part of our duty to defend hospital authorities; but if now, or upon any other occasion, the impartial statement of truth should prove to have that effect, we shall not regret the result.

The election to the Assistant-Surgeoncy, as to every other medical office in the hospital, is, we find, vested in the Council of the College. But the claims of the candidates must, in the first instance, be inquired into by the Medical Committee; and it is the duty of that body to report upon them to the Council. Such, it seems, is the substance of the bye-law upon the subject. Now as to the case before us. Several former students of the hospital having become candidates for the office vacated by Mr. Cadge, their testimonials were received by the Medical Committee, and a Sub-Committee proceeded to inquire into their value. In due time *two* candidates—Mr. Maclise and Mr. Statham—were selected from the entire number; and of these the preference was given by the Committee to Mr. Maclise. This recommendation was, we are informed, unanimous.

Respecting the claims of Mr. Maclise, it is unnecessary to say more than that they consist in his published works on the archetype skeleton and on surgical anatomy. With their merits our readers are fully acquainted. Of Mr. Statham we have learned that, after having distinguished himself at the Examinations for Honours in the College, and in the University of London, and having held office in the hospital, he assiduously and practically studied anatomy and surgery at Paris; and we further understand, that the manuscript records of his labours were considered by the Medical Committee to be highly meritorious. Mr. Statham, moreover, served as surgeon in the army of Schleswig-Holstein during the recent contest in that country, and was attached to one of the large hospitals for the wounded. Besides the notes of individual cases observed by him, he laid before the Medical Committee a manuscript, containing general inferences suggested by what he witnessed; and this paper was considered by the Committee to evince much aptitude on the part of its author for the investigation of surgical diseases. The Committee had also evidence before them, that Mr. Statham had successfully performed important surgical operations.

The Report of the Committee, containing a full detail of the career and the labours of all the candidates, was considered by the Council at repeated meetings, one of which was held for the purpose of a conference with the Dean on the part of the Medical Committee; and, at length, the subject

was concluded by the adoption of the following resolution, which has since been transmitted to the Medical Committee:—

"Resolved,—That the Medical Committee of the Hospital having, in their Report to the Council on the subject of the relative merits of the candidates for the office of Assistant-Surgeon, stated, 'that the choice must lie between Mr. Statham and Mr. Maclise,' it appears to the Council that, great as Mr. Maclise's merit is, yet Mr. Statham, whose 'perfect aptitude for the duties of the office' the Report recognises, is more fully qualified, by practical experience and acquaintance with the operative department of surgery, for the peculiar duties of Assistant-Surgeon; that, therefore, Mr. Statham be appointed Assistant-Surgeon to the Hospital."

But how came it, that the conclusion arrived at by the two Bodies was different? We think that the explanation may be found in the Report itself. For if the Committee did not give to Mr. Maclise's practical experience and aptitude, a sufficient degree of weight to balance the strong statement and the high commendation they (as the resolution of Council itself shows) used in reference to Mr. Statham; it is not unnatural that a body of laymen, looking to the care of the patients in the hospital as the primary object for consideration, should prefer the man appearing on the face of the Medical Report to be by his previous habits the better fitted for this purpose. It may be very wrong, and we hold it be so, for laymen to act in such a the matter; but still, looking to the bye-laws under which the Council acted, it is plain that there was nothing unconstitutional in their proceedings. Neither was such a course "unheard of" in the College; for it is well known, that the Council always exercise an independent judgment in matters of the same kind.

Here we would willingly have taken leave of this subject, but for some remarks that it has elsewhere elicited. What connexion there is between the election of an Assistant-Surgeon to the Hospital and the expenditure of the capital of the College, is not very apparent; and yet it is stated, that the College has drawn for its "daily support," on its endowed funds, invested for other purposes, to the extent of 23,000*l.*, etc. This is a pure invention; and, moreover, the inventor has carefully concealed the facts, that a large chemical laboratory, a large dissecting-room, lecture-rooms, the great library and hall, have all been built and furnished, and the expenses defrayed out of this capital. We have yet to learn, that the erection of new buildings is properly included under the head "daily support;" and that capital is not as properly, as it is customarily, used to defray the charges.

It is also said, that undue influence has been exercised over the Council in the late election, and insinuated that an individual member of the College has governed it for many years. If this be true, what comes of the statement already adverted to, that a departure from the recommendation of the Medical Committee is "unheard of"? To the absurd allegation, that secret influence was exerted on the Council, a sufficient answer will be found in the names of that body (a), eighteen of whom we find took part in this election. Their position, their high honour, and their unblemished character, are amply sufficient to refute the calumny.

BITTER BEER.

The following Report of Professors Graham and Hofmann on Bitter Beer will be read with interest by our readers. Its result did not at all surprise us. We never, for a moment, suspected that such a man as Mr. Allsopp could be guilty of any kind of falsification, although we are extremely glad that he has come forward in this decided way to clear himself from even the suspicion of being a party to adulteration. We are also prepared to say that, with the accurate details now before us of the expense of strychnine, and of the quantity which is necessary to impart bitterness to beer, we think it extremely unlikely that the report of the falsification with strychnine was based on any sure foundation.

At the same time, we should be glad to see the investigation pushed a little further. The account Messrs. Graham and Hofmann give of M. Payen's opinions, does not exactly accord with that gentleman's original assertion. In the statement given in *L'Union Médicale*, we are unable to find any such expression as "the falsification had no doubt ceased." It also clearly appeared from this statement, that the precautions of the police alone had prevented the fraud from being practised in France; whereas, in England, where checks against adulteration are not provided, it was supposed to have been carried on without molestation. It also does appear, that only ten or twelve years since, M. Pelletier, (M. Payen's informant,) had an order for an "extraordinary amount" of strychnine, which he afterwards learned was exported to England, and intended to "complete the bitterness" of certain kinds of beer. Moreover, we now learn, that Chevallier has hinted at a similar adulteration, in a work published about a year ago in France. How did MM. Pelletier and Chevallier gain their information?

Messrs. Graham and Hofmann must allow that these circumstances are calculated to excite suspicion; and when they state that the charge has been "vaguely made," they might have spared us the reproach, since a charge of the kind could not have been made otherwise. Vague as it may have been, it was our duty to give it publicity, and to endeavour to attract to it the attention of those who were capable of investigating its truth or falsehood. Even now, after the expression of the opinions of these two eminent chemists, and after the facts they have brought forward, we still maintain that the Government will be guilty of the grossest neglect of public duty, if it do not institute a thorough investigation into the whole subject.

There is one expression in the Report to which we most strongly object. Messrs. Graham and Hofmann state, that "it thus appears, that the charge which has been put into the mouth of M. Payen was never made at all by that gentleman, so far as it applies to the present practice of English brewers." This is a most unfair and unhandsome charge against us, which we certainly did not expect from such a quarter. It is also a mis-statement of the facts. We put no charge in M. Payen's mouth; we simply translated what he said; if Messrs. Graham and Hofmann assert, that we have given a false report of M. Payen's lecture, we deny the charge, and challenge them to point out where the error is.

London, April 26th, 1852.

.Report.—Having undertaken, at the request of Mr. Allsopp, an inquiry into the purity of bitter beer, with particular reference to its alleged adulteration by strychnine, we now submit the results which we have obtained upon the subject:—

Strychnine, or strychnia, the alleged substitute for the hop, is a fine crystallizable substance, extracted from nux vomica, and belonging to the class of vegetable principles termed alkaloids, of which quinine from Peruvian bark, and morphine from opium, are

the most familiar examples. These substances, although susceptible of the most valuable medical application in small doses, are, generally speaking, remarkable for their energy as poisons, and for the intense bitterness of their taste,—two properties which are developed in strychnine in the highest degree. Half a grain of the latter substance would poison, and the bitterness of the same minute quantity is perceptible in every drop of six or eight gallons of water in which it is dissolved.

It may be stated at once, that the quantity of strychnine which we find necessary to impart to beer the degree of bitterness possessed by pale ales is, for a gallon of beer, one grain of strychnine, or double the fatal dose. The price of strychnine is about 16s. the the ounce, which does not amount to so much as one penny per grain. Estimating the annual production of pale ale in Burton at 200,000 barrels, the strychnine required as a bitter would, however, amount to 16,418 ounces, and cost 13,158*l.*; while nobody believes that so much as 1000 ounces of strychnine are annually manufactured over the whole world. The bitterness obtained by means of strychnine is equal in degree to that of the hop, but very different in kind, and easily distinguished when the two bitters are compared. The bitter of the hop is immediate in its action upon the palate, is accompanied by a fragrant aroma, and soon passes off; while that of strychnine is not so instantaneous, but, when the impression is once communicated, it is more lasting, and becomes, from its persistence, like that of a metallic salt. The bitter of strychnine is, indeed, easily distinguishable from that of the hop, when deliberately tasted.

Still it would be highly desirable to be able to identify strychnine in beer, by the actual extraction of the substance, and the application to it of a chemical test of absolute certainty. Fortunately, those poisons which have the most violent action upon the animal economy, possess often also the best marked re-actions, or their physiological and chemical properties are equally salient. Thus, arsenic and hydrocyanic acid are the most easily detected of chemical substances; and strychnine proves to be not far behind them in this respect.

A quantity of strychnine, not exceeding one one thousandth part of a grain, is tested and recognised to be strychnine in the following manner:—The powder is moistened with a single drop of undiluted sulphuric acid, and a small fragment of chromate of potass placed in the liquid. A beautiful and most intense violet tint immediately appears at the points of contact, and is speedily diffused over the whole liquid. Although most intense, the colour disappears entirely again in a few minutes. The admixture of the smallest quantity of organic matter, however, interferes with the success of the process. In order to apply the test, in operating upon a complex liquid like beer, the strychnine must first be extracted from the liquid and obtained in a pure or nearly pure condition. This difficulty, which appears at first considerable, may be readily surmounted, and the strychnine, if it really exists in beer, be separated, and its nature established in the most certain manner.

For this purpose, two ounces of ivory-black, or animal charcoal, were shaken in half a gallon of beer to which half a grain of strychnine had been purposely added. After standing over night, the liquid was found to be nearly deprived of all bitterness, the strychnine being absorbed by the charcoal. The liquid was now passed through a paper-filter, upon which the charcoal containing the strychnine was collected and drained.

The next step was to separate the strychnine from the charcoal. This was readily effected by boiling the mixture for half an hour in eight ounces of ordinary spirits of wine, avoiding loss of alcohol by evaporation. The spirits, which now contained the strychnine, were next filtered, and afterwards submitted to distillation. A watery fluid remained behind, holding the strychnine in solution, but not sufficiently pure for the test. The final purification was accomplished by adding a few drops of potass to the watery fluid, and then shaking it with an ounce of ether. A portion of the ethereal solution evaporated upon a watch-glass, left a whitish solid matter of intense bitterness, and this was recognised to be strychnine, by giving the violet tint previously described, upon the application to it of sulphuric acid and chromate of potash.

Having satisfied ourselves by repeated experiments with samples of beer to which strychnine had been previously added, of the never-failing efficiency of the above method of extraction, we now proceeded to the actual examination of the commercial article. With this object, a series of samples were taken indiscriminately from the stores of a considerable number of the London bottlers who supply the public with Allsopp's pale ale. We mention the beer of the following firms, whose goods were severally examined by the processes which we have above described, and from whom we have documents in hand proving the origin of the beer, and the date of its arrival at their stores from Messrs. Allsopp's brewery:—

*C. Barron and Co., 19, Pall-mall.
Barker and Blewett, 211, Sloane-street.
G. and M. Blockey, Duke-street, St. James's.
John Blockey, 104, Ebery-street, Pimlico.
*C. H. Bowen, 101, Fenchurch-street.
*R. B. Byass, Langbourne-chambers, Fenchurch-street.
Child and Co., Leicester-square.
L. Clow, Princes-street, Fitzroy-square.
Crimp and Ward, Old Broad-street.
Daukes and Rodick, Exeter-hall Vaults, Strand.
Nath. Easty, 138, Upper Thames-street.
*Findlater, Mackie, and Co., 1, Upper Wellington-st., Covent-garden.
M. B. Foster and Son, 56, Brook-street, Bond-street.
Friend and Co., Abchurch-lane.
George Jones, 8, Billiter-street.
E. and G. Hibbert, 7, Jewry-gardens, Aldgate.
W. G. Hollebone, 1, Lower Eaton street.
W. Mabey, Lloyd's Coffee-house, Royal Exchange.
J. Macdonald, 9½, Queenhithe, Upper Thames-street.
*Moline, Harper, and Moline, London-bridge.
Nisbet, 11, Jermyn-street.
Padget and Son, Pantechnicon.
Rose, Brothers, 257, Oxford-street.
A. Suter, 65, Fenchurch-street.
J. Wallis and Co., Milbank-street, Westminster.
White and Price, Mark-lane.

It may be stated that, with the exception of the five varieties marked with an asterisk, the casks from which these samples were taken had all been received in London before the 20th of March, *i.e.*, the period the possible use of strychnine in the manufacture of bitter beer was first brought before the English public.

Not one of these varieties of beer, when tested with the greatest scrupulousness, gave the slightest evidence of the presence of strychnine.

The charge of adulteration of beer by strychnine has been proposed in a manner so vague, that it is difficult to fix it, and try its validity. The existence of the adulteration is not alleged in any particular sample of beer, nor the practice ascribed to any individual brewer or dealer. An English journalist adopts the charge upon the report that such an opinion is entertained and expressed by a French chemist of distinction, M. Payen, in his public lectures at Paris. From this gentleman we have since obtained explanations which define more closely the kind of charge which was actually made by him. The late M. Pelletier, the well-known manufacturer of organic products in France, had received, at one time, an order for an extraordinary quantity of strychnine, of which the destination was at first unknown to him; but which he afterwards learned had been entirely exported to England, and used, as he informed M. Payen, to complete the bitter of certain kinds of beer.

We have reason to know, although it is not stated by M. Payen, that these remarks of Pelletier refer to a period of ten or twelve years past; and further, although not informed of the amount of the order, we have good authority to state, that fifty or a hundred ounces would have been considered a large order for strychnine at that time. The calculation already given, shows how utterly insignificant such a supply of strychnine would be for its imagined application in the pale ale breweries. It is likewise known that the manufacture of strychnine has not been on the increase in France of late years.

M. Payen excuses his statements on the ground, that similar suspicions are conveyed in a French work, on "Alterations and Falsifications," by Chevallier, published nearly a year ago, but which have not hitherto received any formal contradiction in England. Notwithstanding the latter circumstance, our distinguished correspondent concludes by expressing his regret that he ever said "that the fraud appeared to have been practised," although he had added the remark at the time, "that this falsification had no doubt ceased."

It thus appears, that the charge which has been put into the mouth of M. Payen, was never made at all by that gentleman, so far as it applies to the present practice of English brewers; and with reference to anterior times, that the charge reposes simply and exclusively upon the privately expressed opinion of a deceased chemist, the grounds of which are entirely unknown to the world, and must ever remain so.

The sifting nature of the chemical examination which the beers of Messrs. Allsopp's manufacture for many months past have been subjected to, fully establish their incontestible purity. Indeed, no one who has witnessed, as we have done, the open manner and

gigantic scale in which the operations are conducted in their establishment, could entertain the idea for a moment that any practice involving concealment was possible. But even in the absence of all such scrutiny, the idea of strychnine being mixed with beer anywhere, or in any circumstances, involves an amount of improbability which might well dispel all suspicion on the subject.

There is an Act of Henry VII. which prohibits the *adulteration* of ale by brimstone or *hops*. The place of the hop was then supplied by sage, horehound, chamomile, and other indigenous bitter plants. Since that period, the character of the national beverage must have undergone a silent revolution, for all varieties of beer, both pale and brown, now owe their distinctive properties to the hops which are boiled in the malt infusion, and fermented along with it, as completely as wine owes its peculiar character to the grape. Substitute any other bitter for the hop, and fermented wort would no longer be recognised as beer.

Were mere bitters all that is required, it would be easy to prove that the extract of quassia would supply a bitter which is perfectly harmless and agreeable, and infinitely less expensive than strychnine.

But the process of brewing pale ale is one in which nothing but water and the best malt, and hops of the first quality, are used, and is an operation of the greatest delicacy and care, which would be entirely ruined by any tampering with the materials employed. Strychnine could not fail to be rejected, from the ungrateful, metallic character of its bitterness, independent of all objections of a more serious kind. This peculiarity of taste is also calculated to betray its presence. Small, too, as the proportion of strychnine may be, which is necessary to impart the degree of bitterness of pale ale, the quantity rises, as has been seen, to a poisonous dose in half a gallon of the fluid; and as this poison is one of those which are known to accumulate in the system, its poisonous action would inevitably follow, in occasional cases, upon the consumption of much smaller portions of beer when continued for many days without intermission. The violent tetanic symptoms of poisoning by strychnine are also such as could scarcely fail to excite suspicion and alarm. Add to these disadvantages, the certainty of the means of detecting strychnine in beer by the chemical tests described above, which any medical man or practical chemist can apply, and the chance of the use of so dangerous a substance for any purpose of adulteration, becomes in the last degree improbable.

Brewery, Burton-on-Trent.

THE LATE MR. DALRYMPLE.

[From a Correspondent.]

It is with profound regret that we announce the decease of Mr. John Dalrymple, of Grosvenor-street, at a quarter before ten on Sunday, the 2nd instant,—a regret in which all who know his worth will readily sympathise. Like his eminent predecessor, Frederick Tyrrell, he has been cut off in the flower of his age and the height of his usefulness, just when reaping the reward of his long and meritorious labours in the field of ophthalmic science. He has passed away from us at the very time that his ripe judgment and extensive experience rendered his opinion of the highest value. When a man reaches threescore and ten, or fourscore, his faculties usually decay, and his work is done; but far different is it when, as in the present instance, a professional man is struck down in the very prime and vigour of his days. That is indeed a heavy loss; and what Mr. Dalrymple had done, proves what might have been expected of him had his life been spared to the full age of mankind.

A warm and uninterrupted friendship of more than twelve years enables the writer to bear testimony to the worth of his departed friend. In him, simple, unassuming manners and upright conduct were combined with great clearness of perception, and remarkable tact in diagnosing the points of a case, and its appropriate treatment. He was eminently cautious, very chary of resorting to operations in doubtful cases, and although not strictly a brilliant operator, was equally careful and successful.

Mr. Dalrymple was an able microscopist, and contributed some valuable papers to the Royal Society; but his *magnum opus* was his noble work on the pathology of the eye, which will be an enduring monument to his fame.

The social disposition, honourable feelings, kindliness of heart, and many estimable qualities of John Dalrymple, combined with his extensive information, will endear his memory, as it endeared the man, to a large circle of friends: and to no one more than to him who pens this tribute of regard. It will be satisfactory to the Profession to know, that the concluding part of Mr. Dalrymple's great work on the Pathology of the Human Eye is in print, and only waits the colourer, for publication. W. W. C.

REVIEWS.

Researches into the Pathology and Treatment of Deformities in the Human Body. By John Bishop, F.R.S., Member of the Council of the Royal College of Surgeons of England, etc. Pp. 266. London: Highley and Son. 1852.

Lateral Curvature of the Spine; its Causes, Nature, and Treatment. By R. W. Tamplin, F.R.C.S. Eng.; Surgeon to and Lecturer on Deformities at the Royal Orthopædic Hospital, etc., etc. Pp. 44. London: John Churchill. 1852.

These two volumes are written with widely different objects. The first is a philosophical disquisition on the causes and principles of treatment of deformities; the second, a slight sketch of the causes, the symptoms, and of the treatment of lateral curvature of the spine, adopted by the author. The former is addressed to the members of the Medical Profession alone, and requires attentive study and reflection; the latter is adapted for, and addressed rather to the friends of those afflicted with lateral curvature than to the Profession, although certain principles of the pathology of spinal curvature are enunciated in its pages.

Commencing with some remarks on the present condition of surgery in relation to deformities, Mr. Bishop passes first in review, "the transition from the normal states of many structures; such as those of the bones, the joints, the ligaments, and the muscles, as likewise the constitutional, chemical, and mechanical actions involved in those changes." The parts of the osseous system concerned in the production of deformities are more especially those which transmit the weight of the head and other parts to the ground. The density, elasticity, and other mechanical properties of the osseous tissue are admirably adapted for the purposes to which bone is applied, and any considerable variation in those qualities, or the chemical composition of bone, especially the changes by which its elasticity is diminished, materially assist in the production of many deformities. The arrangement of the osseous matter so as to produce the greatest amount of resistance, and the causes of mollities and fragilitas ossium are discussed in this chapter.

One of the most, if not the most important division of the work is that on the vertebral column. In this chapter the construction, the natural curves,—the mode of production, and the value of these curves,—the capability of resistance to super-incumbent pressure,—the flexibility and elasticity of the entire column,—the ligaments of the spine, and the effects of equal and unequal pressure on the inter-vertebral substance are discussed. It has been stated by physiological writers of great repute, the illustrious Magendie among the number, that the normal triple curve of the spinal column conduces so much to its power of resisting super-incumbent weight, that the spine is sixteen times stronger than if it were straight. Mr. Bishop successfully combats this opinion, and demonstrates the error on which it is founded. The calculations on which such enormous increase of resistance is based, evidently depends on the resistance to vertical pressure of a straight elastic spring. But the spine is originally curved, and any forces applied to its extremities will necessarily increase the curve in a similar proportion that the force, acting on an originally straight

spring, produces certain curves in its axis. "So far, then," says Mr. Bishop, "from being stronger in consequence of being originally bent into several curves, the spine is, in fact, much weaker; and the greater the radius of curvature at any point of the axis, the less will be the strength." And "the advantage of the curved form is, that the shocks and jars applied at either end of the spine tend to bend the axis, which would, if straight, crush some of the vertebræ in consequence of the force acting on them in a perpendicular direction." In the section on the ligaments of the spine, we have the important observation, that while in robust persons the ligaments are endowed with considerable elasticity, in the weak and relaxed habit of body, both the strength and elasticity are much impaired, elongating on the application of a smaller force, and returning with less energy to their natural condition after the removal of the extending force. The compressibility of the inter-vertebral fibro-cartilages, and the time required to restore them to their pristine condition after long-continued pressure produced by the erect position of the body for many consecutive hours, is greater than is commonly supposed, and the restoration by the recumbent position occupies several hours. The compression produced by the erect position of an adult during the entire day amounts to an inch or about one-fourth of the entire natural depth of the inter-vertebral cartilages. As the natural curves of the spine are produced by the unequal thickness of the bodies of the vertebræ and the inter-vertebral cartilages, all abnormal changes in the figure of the spine must result from some change in the figure of these parts; and as the inter-vertebral substance is subjected to equal pressure when in the erect position, it follows that the constant maintenance or too frequent repetition of other than the erect position will affect the figure of the spine, and tend to produce curvature.

"Hence," says our author, "it is obvious, that, whenever the spine is curved in any one direction, some portion of the inter-vertebral substance bears a larger proportion of the whole compressing force of the superincumbent organs than the rest; and, if such unequal distribution of the force be long maintained, it must tend to derange the functions. We have seen, that when the inter-vertebral cartilages have been subjected to continued pressure, they do not instantaneously recover their primitive condition. From this it may be readily inferred, that, if the surface of the cartilages has been unequally acted on by a force applied day after day for some time, it will become so much compressed in one part, and expanded in the opposite, as to assume a new figure, adapted to the abnormal attitude which gave rise to its unequal compression. In fact, it becomes diseased by the influence of simple mechanical compression, independently of other causes. The inter-vertebral cartilages having thus been made to assume a new figure, occasion deformity of the spine, and are, indeed, in all probability, the usual seat of lateral distortion when it is merely of a mechanical character."

The mischief produced by this abnormal direction of the pressure is not confined to the inter-vertebral substance, but extends to the vertebræ. Mr. Bishop is of opinion, that the persons most subject to distortions of the spine are those whose bones contain less than the normal proportion of earthy material.

In the third chapter, after a general disquisition on the physiological actions of muscles, the author discusses the question of myotomy and tenotomy. He is decidedly opposed to these operations, because, when once the passive elongation of a muscle is lost by removing the resistance in cutting across the tendon, it never recovers its original length, and loses much of its force. He says:—"Now, as the muscles, after their division, become shortened, and have no power to elongate themselves, their union must take place by the production of new matter, which fills up the interval between the divided parts. By this means, muscles are lengthened without being stretched, and do not acquire the tonicity and extension of their normal state, and hence their loss of power." He draws the conclusion, that myotomy for lateral curvature is not justifiable on any rational or practical ground, and that tenotomy is followed by such debility, from loss of tonicity of the muscles, as to be positively injurious. The only cases in which these operations are, in his opinion, admissible, are strabismus and torticollies.

A large portion of the body of the book is necessarily occupied with the mechanical causes of distortion. In this part the effects of different occupations which cause the workman to assume certain unnatural positions are fully discussed. Among the causes of distortion the carrying of weights on the head, the back, in front of the body, or on one side, also the positions demanded by the use of a wooden leg after amputation of one of the lower extremities. Other causes of distortion are enumerated, among which are the use of crutches, anchylosis of the knee or hip-joint; unequal length of the legs, lying and sitting in unfavourable positions, and rowing, all of which are viewed by the Author as tending to turn the spine from its proper curves. Of these causes of lateral curvature of the spine, the unequal length of the legs is perhaps the most important, and the most easily overlooked. When one leg is shorter than the other, either in consequence of some congenital deficiency of development, or from rachitic curve, it is evident that in standing or walking, the body must be more or less thrown over to the opposite side. The Author remarks, that when this shortening of one of the lower limbs exists, "the effect on the trunk is similar to that which occurs when one limb becomes shorter than the other, owing to disease of the hip-joint or otherwise; and it is gratifying to find that the trunk, after having been so distorted, will resume its normal figure when the leg has become straight, or is rendered of equal length with the opposite limb." The mechanical effects of lateral or posterior curvature of the spine on the motion of the ribs, their relative position and the results of those changes of position on the thoracic and abdominal viscera are carefully described.

Passing over a long, interesting, and important discussion of the deformities of the lower extremities, in which much valuable matter and many novel views are contained and enunciated, simply from want of space, we arrive at the ninth chapter, on the pathology and morbid anatomy of deformities.

The morbid anatomy of spinal curvature unattended by caries is, in its early stages, almost unknown. Great contrariety of opinion on this subject subsists. Some affirm that the disease is in the ligaments, the fibro-cartilages, or the vertebræ; while Mr. Bishop is of opinion that these changes are secondary, resulting from frequently-repeated, long-continued malpositions of the body.

The changes in the vertebral column from caries, mollities ossium, rickets, etc., are elaborately described, and several illustrations from marked and interesting cases are given. The most singular of these is a case of hypertrophy and ossification of the inter-vertebral substances, giving rise to a convexity forwards. This chapter closes with an account of the malignant diseases of bones; and, after devoting some pages to the subject of rickets, the author passes on to the discussion of the methods of alleviation and cure of the deformities he has described.

It is evident, from the state of the vertebral column in old and confirmed cases of ordinary lateral curvature not the result of caries or malignant disease, that a cure is utterly hopeless. Consequently, it is of the greatest importance that early attention should be paid to every case, and such means adopted as are most capable of obviating the cause of the deformity. The adaptation of the means to be employed must, in Mr. Bishop's opinion, depend on a familiarity with animal mechanics.

"Whoever," says he, "undertakes to cure distortions, should be perfectly conversant, not only with the structure of the human frame, but also with the bearing of each part of it on every other; for it is not enough to bring in aid the extraneous force of an instrument to remedy a distortion, however well qualified it may be to correct the particular evil, without having the certainty that its use will give rise to no other derangement of the system; and this can only be known from a careful investigation into its relative effects on the several parts of the body considered as a complicated machine—a problem which generally does not admit of an easy solution."

The methods of treatment now in use are classified under three heads:—those designed to stretch the body either in a horizontal or vertical position; those which tend to prop the body or limbs, and the recumbent position—either prone or supine. The author enters very fully into the discussion of the relative value of each of these methods, their uses and abuses. Our limits compel us to confine ourselves to the following extracts, as embodying the grounds of the author's idea of the treatment of simple lateral curvature in its early stage:—

"Unless, indeed, there be disease of the bones of the spine, the

origin of ordinary cases of lateral curvature is rarely found in the spine itself, but is produced by extraneous force; for the bones, muscles, ligaments, and cartilages, are all in a state of uniform action on each side of the mesial plane of the body, and the tendency of the spine to bend must necessarily be in that place."

and—

"The direction and position of the surface of the sacro-lumbar articulation may be varied by the length and disposition of the legs; if one leg be shorter than the other, the articulation will be inclined in standing towards the side of the shorter leg; the same thing occurs when one leg is flexed at any joint while the other is extended."

and—

"The progress of lateral curvature, not originating from organic disease, may be divided into three stages. The first comprehends those cases where the curvature depends upon attitude, or the presence of extraneous force, without having produced any altered figure of the vertebræ or absorption of inter-vertebral cartilage. The second comprises those cases in which the curvature results from a slightly-altered figure of the vertebræ and cartilages in very young and growing persons, the bones not being yet sufficiently hardened with their due proportion of earthy constituents, and when the curvature is produced by extraneous forces. The third embraces cases of long duration, in which the vertebræ have assumed an altered figure, and have become hardened by an increased supply of earthy constituents. The persons are of a more advanced age, and the body has acquired a position of equilibrium corresponding to the distortion of the spine. The great objects to be kept in view by those who have the management of children are, to see that none of those causes which produce ordinary lateral curvature be suffered to act, and to attend to the physical condition of the body in the earlier stages of developement."

In the foregoing analysis we have confined our remarks to the principles on which the treatment recommended by the author is founded. Mr. Bishop has done good service to the Profession in the publication of his work.

Mr. Tamplin's essay is, as we have already said, a simple exposition of the principles by which the author is guided in his treatment of lateral curvature. Mr. Tamplin is of opinion, that "the immediate cause of deformity (lateral curvature) in all cases is purely mechanical, namely, the superincumbent weight of the head and upper extremities, combined with an instinctive effort, always in operation, to retain the head in a perpendicular position with the sacrum, with inability of the muscles and ligaments to accomplish this object when once a permanent curvature has taken place."

The author takes a similar view of the result of deformities of the lower extremities in producing lateral curvature, which arises, according to him, from the following circumstances:—

"1st. From any cause by which the movements of the lower extremities are rendered irregular; in other words, where the uniformity of their action is destroyed.

"2nd. From general debility, or simple loss of tone of the system; from general debility consequent upon or combined with true rachitis, with its attendant and unhealthy state of the constitution.

"3rd. From any occupation by which the muscles of one side, or of one extremity, are more frequently exercised than those of the opposite side."

In the description of the pathology of lateral curvature, we have the remark, that

"The intervertebral substance, from the continued and undue pressure to which it is subjected on the concavity of the curve, becomes at first compressed, and eventually, in the most severe cases of many years' standing, absorbed; while the ligaments are elongated on the convex side, and contracted on the concave side, offering the most obstinate resistance."

Mr. Tamplin is of opinion, that

"In those cases in which the curve is slight though permanent, even when of some years' duration, as a rule it admits of being perfectly cured; and the basis, if not the whole, of the treatment is the taking off the superincumbent weight of the head and upper extremities by mechanical support, by instruments of his own invention, and, if necessary, invigorating the system by appropriate internal medicines."

He objects to the use of the exercises recommended by other practitioners, on the score that such exercise will cause an increase of power in the muscles which will in turn increase the deformity.

SCOTLAND.

PARTURITION AMONG THE ESQUIMAUX.

At a recent meeting of the Obstetrical Society, Dr. James Struthers exhibited the pelvis of a female Esquimaux, which was chiefly remarkable for the unusually large dimensions of the brim, cavity, and outlet, allowing the largest fœtal head to pass with great ease in almost any direction. The following are the diameters of the brim:—Transverse, 6 inches; conjugate, $4\frac{5}{8}$ inches; oblique, $5\frac{3}{8}$ inches. Of the cavity:—Transverse, $5\frac{3}{8}$ inches; conjugate, $5\frac{3}{8}$ inches; oblique, $5\frac{3}{8}$ inches. The transverse diameter of the outlet was $5\frac{1}{8}$ inches; and the pubic arch was unusually wide.

Dr. Struthers received the pelvis from Mr. G. C. Pirie, who found it last summer under a cairn of stones, the common mode of burying among the Esquimaux,) near Cape Hooper, in Davies' Straits. It is an interesting fact, (of which Mr. Pirie satisfied himself, thereby confirming the statements of various writers on Greenland,) that the Esquimaux women have much safer and more rapid labours than the women of this country. There the whole process of parturition is left in the most absolute manner to nature. As soon as the woman begins to complain, she retires to a low skin hut, built for the purpose, into which no one is allowed on any account to accompany her. Before the lapse of an hour, she generally makes her appearance with the baby on her back. Not unfrequently labour comes on unexpectedly. Such a case came under Mr. Pirie's own observation. The woman left the ship, retired behind a block of ice, and came back within half an hour with the child in her hood. It is stated that the cord is not divided until the placenta has come away, and that the division is effected by the teeth of the mother. Miscarriages, twins, and monsters are of rare occurrence, and it is a very uncommon thing for a woman to die in childbed.

EXHIBITION OF QUININE IN TYPHUS AND TYPHOID FEVERS.

On this subject, Professor Bennett read a paper to the Medico-Chirurgical Society, on Wednesday evening. It appeared, that about the month of November last, Professors Benuett and Christison had received communications from Dr. Dundas, of Liverpool, mentioning the beneficial results he had found to follow the exhibition of quinine in the continued fevers of warm climates. So strong were the representations of Dr. Dundas, that Professor Bennett, whose period of clinical duty in the Infirmary had at that time just commenced, determined to give the remedy a fair trial. The doses Dr. Dundas recommended were ten grains every second hour. Dr. Bennett had given quinine in seven out of fourteen cases of typhus or typhoid fever admitted into the Royal Infirmary during the period from November to the end of February. In all seven the physiological effects of the remedy had been produced. In most of the cases, the seventh was the day of the disease on which the treatment of quinine was begun, in some it was later; one patient, however, had it on the sixth day, and none later than the tenth. In one case, 205 grains of quinine had been taken in eighteen doses. In five others about 80 grains had been taken. Dr. Bennett had in none of these instances found the quinine to cut short the disease, or in any way favourably to influence its progress. In one case convalescence had been delayed till the forty-second day. At the same time, Dr. Bennett, thought it proper, in bringing the subject before the Society, to mention, that the experience of some other physicians had been more favourable. Dr. Graves, of Dublin, for example, had written to Dr. Dundas to that effect, and so had Dr. Kelly, of Drogheda, who had treated eight cases with the happiest results. Professor Christison's experience had as yet been limited to one case, that of a girl who had contracted typhoid fever in the hospital when recovering from another disease. In it the employment of the remedy had certainly produced no favourable effect,—it was now the forty-second day, and no marked convalescence had commenced. He regarded Dr. Bennett's experiments as of additional value from having been made *coram publico*, in the presence of a large number of intelligent students, many of whom had been from time to time examined on the very cases themselves. Important as the inquiry was, he much feared that the discovery of quinine as an antidote in continued fever would prove of but little avail, unless the additional discovery of new cinchona forests was also made.

Dr. William Robertson had also administered the quinine in some cases, in none with benefit. He had in two cases observed very alarming symptoms to follow its exhibition, a state of almost complete coma having been induced.

Dr. Maclagan had recently learned from his son, Dr. Philip Maclagan, of the 20th Regiment, at present in Montreal, that good effects had followed the administration of quinine in the form of continued fever lately prevalent there.

Dr. Begbie had had no experience of quinine in continued fever; but in the remittent fevers of children he had long employed it with marked benefit. In such cases, he was in the habit of prescribing quinine, while the tongue was foul and the skin hot, and without even the use of a purgative. He frequently found the quinine to arrest in four or five days this form of fever, which generally continued for ten or twelve, and often for a much longer period.

PROFESSOR BALFOUR'S *ELEMENTS* OF BOTANY *versus* PROFESSOR BALFOUR'S *MANUAL* OF BOTANY.

While Messrs. Adam and Charles Black are busily advertising the former work, Messrs. Griffin and Co. are, with even greater energy, calling the attention of the lovers of botanical pursuits, and especially students, to the same Professor's Manual. We can imagine a student being very much difficulted as to whether he should purchase the Elements or the Manual. The former is certainly the newer work; but who can entertain a doubt as to the excellence of the latter, after reading the following advertisement, which appeared in Wednesday's *Scotsman?*—

"Professor Balfour's Text-book of Botany. A Manual of Botany: being an Introduction to the Study of the Structure, Physiology, and Classification of Plants. By John Hutton Balfour, M.D., F.L.S., F.R.S.E., Professor of Medicine and Botany in the University of Edinburgh. Second Edition, 670 pages, with 833 Wood-engravings. Price 12s. 6d. 'All my pupils want it.'—*Professor Balfour.* 'All my pupils are waiting for it.'—*Professor Balfour.* 'I must have the book complete for my pupils in spring.'—*Professor Balfour.* 'The most masterly digest of the science which has yet appeared.'—*Witness.* 'Beyond all comparison the best introduction to the most delightful of all sciences.'—*North British Mail.* 'Remarkable for comprehensiveness and cheapness.'—*Scottish Guardian.* 'Very complete.'—*Atlas.* 'A mass of valuable and interesting information.'—*Weekly News.* 'Admirably arranged.'—*Bentley's Magazine.* 'The model manual of botany.'—*Tait's Magazine.* Griffin and Co., London and Glasgow."

Can it be, then, that Dr. Balfour really wishes his students to provide themselves with the manual of the Messrs. Griffin? or is it not more probable that the Messrs. Griffin are only laudably anxious to get rid of the book their enemy has written, and for that purpose are advertising right and left.

We had thought that the little dispute between the botanical Professor and his former publishers had been got over. We do not remember ever to have read of any peculiar severity attending the bite of that fabulous creature the *griffin*; but we suspect that Professor Belfour, must feel rather sore on that point—so we dismiss it.

GENERAL CORRESPONDENCE.

OF THE TREATMENT OF NÆVUS.

[To the Editor of the Medical Times and Gazette.]

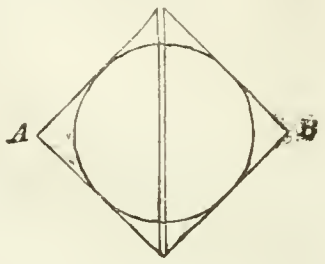
SIR,—Subcutaneous vascular tumour, or nævus, is variously treated by extirpation, compression, destruction through chemical agents, and ligature; each of which means is applicable according to the size, situation, and individuality or peculiarity of the growth; and perhaps of these the subcutaneous ligature is that most generally admissible.

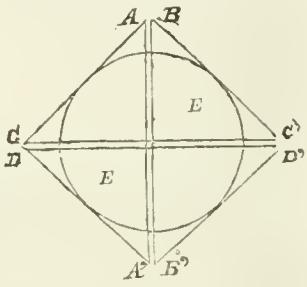
When the skin is not implicated in the disease, it is unnecessary that it should be included in the ligature; the operation is then comparatively painless, and an ugly cicatrix is avoided. But when the nævus is situated upon the eyelid, or immediately beneath the lower lid, it is imperative not to include the integument in the ligature if it may possibly be avoided.

I have several times had occasion to use the subcutaneous ligature, and have never had cause to regret that the skin was not also included.

An operation of this kind was lately performed at St. Mary's Hospital, and Mr. Lane remarked, that it was necessary to repeat the operation, it having been done a few weeks previously, but without effect. Mr. Lane then explained, that he had allowed the ligature to remain forty-eight hours only; that suppuration had been established, but no slough formed; and that he doubted the sufficiency of the subcutaneous ligature, the skin remaining to supply nutrition to the nævus.

I will briefly relate the manner in which I passed the ligature in the cases which were treated subcutaneously. With a curved needle, a strong double ligature was carried well under the base of the tumour and out at the corresponding point on the opposite side. The loop of the silk was cut through, and the armed needle again passed subcutaneously, to correspond to one quarter of the tumour; the other end of the ligature was then carried in a similar manner to pass out at the same aperture. The same being done on the opposite side, and the ligatures knotted at *A* and *B*, each half of the nævus was surrounded by its own ligature. Or, the tumour being large, it will be requisite to use four, instead of two ligatures. Two double ligatures being passed at a right angle through the base of the tumour will form four ligatures on cutting through the loops of the silk, and the base will at the same time be partitioned equally. If one of the extremities of each ligature be now passed subcutaneously around one quarter of the nævus and knotted, each quarter will be included in a separate ligature, but the whole tumour will be constricted only on tying the last knot. For instance, *A B*, *C D* are double ligatures, passed through the base of the tumour *E*. Let *A* be carried subcutaneously, and knotted at *C*, *A'* with *D'* and *B'* with *D'*; but strangulation of the tumour will alone be produced on tying *B C'*. The four ligatures are now intimately connected to form but one, and they will be drawn away as a single ligature, on slightly enlarging the opening at one of the knots, and at the same time the slough will escape.





The operation to which I have already alluded was, in effect, merely compression, extended to forty-eight hours; which was sufficient only, as the case proved, to set up an inadequate amount of inflammation for the closure of the vessels. The ligature being removed, blood was again forced into its old channels, and the slough was therefore prevented. When the skin does not partake of the disease, I have never found these subcutaneous ligatures to fail, if allowed to remain long enough for the slough to form.

I am, &c. B. E. BRODHURST,
Assistant-Surgeon to the Royal Orthopædic Hospital.

14, Brook-street, Grosvenor-square.

ON THE ADMINISTRATION OF CHLOROFORM.

[To the Editor of the Medical Times and Gazette.]

SIR,—The experience I have had in the administration of chloroform for many of my professional friends, the surgeons of this large and important town, will, I hope, justify the few practical remarks I am about to make on what appears to me the proper way of employing it; and I am induced the more to do so from your Leading Article in the *Medical Times and Gazette* of April 3. I quite agree with you, that it is a strange scene to behold "a patient laid upon an operating table, a large piece of folded lint sufficient to cover nearly the entire face, and soaked in chloroform, is laid upon the mouth and nose; as the lint dries, fresh chloroform is added. The inhalation may go on five, fifteen, or thirty minutes. There may be used one drachm, or one ounce of chloroform." If this be the ordinary method in London, no wonder that the blood is poisoned, that it remains fluid and without coagulation, and of a "brownish-purple hue." I have, as yet, given chloroform with perfect success, and without cause for apprehending danger in a great many cases; I have given it for one gentleman no less than twelve times the last eighteen months, in cases of lithotomy; the patients aged from eighteen months to sixty-three years, and every patient is, happily, at this moment, alive and well (a); but I have frequently been asked to give it,

(a) These cases will be published: Mr. S. Parker, the operator, having promised me his notes of them.

when, after a careful examination of the heart and lungs, I have declined to do so, and the operation has been performed without it; and I cannot refrain from repeating the words of one of the experienced surgeons to the Sheffield Infirmary, when giving chloroform for him, in a case in which he was about to remove the breast, "that the operation was sufficient to engage the attention of the surgeon, and that the chloroform ought to be left to the physician only." I confess, in the great majority of cases, I never have it in my power to see the steps of the operation, (the eye should be fixed on the face of the patient, and the finger should never be removed from the pulse,) and to leave the administration of chloroform to a young, inexperienced pupil, "anxious to learn surgery," displays a want of caution that cannot be too much lamented.

The proper way to administer chloroform is very simple: no apparatus of any kind to be kept "in good order" is required; a pocket-handkerchief made hollow in the centre to prevent the liquid coming into contact with the lips and making them sore, is the "instrument" I always use; a bit of lint is placed in the centre, on which 30 drops of chloroform are thrown, increased *pro re nata*. After keeping the handkerchief to the nose for, say, half a minute, it is removed, and the patient permitted to breathe fresh air; the chloroform is again applied, care being taken, from time to time, to give fresh air, and to keep the face sponged with cold water,—a basin of which I always have placed within reach. By this plan, —by giving the chloroform at first gradually, taking care that fresh air is given again and again, that no disease of the heart or lungs exists, and that the chloroform is fresh and pure,—I honestly think the remedy may be used with perfect safety. I have kept a patient in a state of insensibility more than half an hour, and I am certain, at least twenty surgeons in this town can testify, that at all ages, and for almost every kind of operation, chloroform has been given by me with the result of rendering the operation painless, and that, too, without danger to the patient. The chloroform I have used has been obtained from Edinburgh.—I am, &c.

Sheffield. J. C. Hall.

ALBUMEN AND ARSENIC.

[To the Editor of the Medical Times and Gazette.]

Sir,—Some letters have lately appeared in several journals from Dr. Sheridan Muspratt, of Liverpool, and T. J. Herapath, of Bristol, on this subject, impugning the accuracy of the statements and experiments of Mr. Edwards, as described in the "Transactions" of the Chemical Society, and characterising them as absurd, etc.

These gentlemen have, in my opinion, drawn a hasty conclusion; and I might further observe, that their own experiments have not been properly instituted, if they wished to establish the efficacy of albumen as an antidote to arsenic. The making of experiments in the laboratory by boiling up the articles is not, I contend, sufficient proof, inasmuch as they will not apply to the human stomach.

The following experiments, which seem to me the more rational, will show exactly how the matter stands:—

Experiment 1.—Took three grains of arsenious acid, dissolved in sufficient quantity of distilled water; put it into a phial along with one fluid ounce of ovalbumen; shook them incessantly for fifteen minutes, diluted with water filtered; and, on adding a drop or two of hydro-sulphuret of ammonia, and then a little muriatic acid, an abundance of the yellow sesquisulphuret, or tersulphide of arsenic, was produced.

Experiment 2.—Repeated the above, but allowed it to stand for two hours, shaking at intervals; on testing again, arsenic in abundance was evident.

Now, it is impossible to mistake this precipitate for free sulphur from the hydrosulphuret, as a simple mixture of albumen and water only showed no such change.

These two experiments speak for themselves; and it must be admitted that no reliance can be placed on the use of albumen as an antidote any more than on hydrated peroxide of iron, since, if it combines with arsenic, as Baron Liebig and his supporters have stated, to form an insoluble coagulate, it ought to do so immediately, or at least within a reasonable time, else it is worthless; neither is the coagulate that is formed wholly insoluble, as on boiling I have detected arsenic in the filtered liquor.

Hydrated peroxide of iron will, I know, if shaken up in sufficient quantity with a clear solution of arsenic, abstract that body immediately and entirely; but, on the other hand, as Professor Taylor has shown, if you mix the arsenic undissolved with the iron and water, it fails, whether it be kept in contact with it for an hour, day, or week. In cases of criminal poisoning, the arsenic is seldom or never in such a soluble form as can be made by the chemist; hence the difficulty to contend with, and the little reliance to be placed on any antidote, however good in other respects.

Dr. S. Muspratt also states, that this coagulate compound is not poisonous, which the concluding experiment of Mr. Herapath totally refutes, as the administration of a portion to a cat terminated fatally. What can be more convincing proof than this of its inefficacy as an antidote? I am, &c.

John Horsley,
Operative and Analytical Chemist.

The Laboratory, Cheltenham.

THE CHARTER OF THE COLLEGE OF PHYSICIANS.

[To the Editor of the Medical Times and Gazette.]

Sir,—As it is of obvious importance, that every graduate in medicine concerned in the Charter now in contemplation by the College of Physicians, should rightly comprehend to what extent it is likely to affect his professional position, I have no scruple in asking for an early opportunity in your Journal, of directing particular attention to that clause which provides for the admission of candidates without examination.

Draft Charter, sect. 5, "Every person practising as physician in England and Wales, who shall have taken the degree of M.D. at any University of the United Kingdom of Great Britain and Ireland" . . . . "shall be admitted, as a member, without examination, at any time within twelve months from the acceptance of these letters patent, on the production to the censors of his diploma, and such testimonials of character and *professional qualification* as shall be satisfactory to the said censors."

There is scarcely a person, I should imagine, who would not come to the immediate conclusion, that any M.D. holding a diploma of the kind stipulated in Clause V, and producing such general testimonials, as are usually considered satisfactory in similar cases by other Corporations, (the College of Surgeons, for example, in the case of the Fellowship,) would be admitted at once, as a matter of course. He would, nevertheless, find himself, perhaps when too late, altogether mistaken in that belief. Far be it from me to impeach the good faith, or cast a shade of unjustifiable suspicion over the motives of those who devised this particular clause; but, as it stands, it is very evident that the censors will be at liberty, quite in accordance with the terms of this important condition, to keep out of the College in the most arbitrary way in the world, and as long as they please, any graduate they may not have a fancy for.

"J. A.," a correspondent of a contemporary periodical, apparently a good authority in such matters, he himself having, so he says, taken part in a certain ceremonial, when twelve Fellows were elected simultaneously, pleads hard in favour of the liberal sentiments entertained by the framers of this Charter. It is not my present purpose to give any opinion as to how far these sentiments may be relied on; the case is simply as I have stated, and it cannot, I should say, be too early or too extensively made known.

There are other reasons why the College should be called on to explain more precisely what they mean by exacting, during this so-called year of grace, "testimonials of professional qualification" besides the diploma, which, be it observed, they require should be obtained after "regular examination." Thus, one of the most liberal-minded among the Fellows, a man justly held in the highest estimation by the entire Profession, withdrew, in extreme dissatisfaction, from the Council engaged over the Charter, at a certain stage of their proceedings—a significant set-off against the 12-Fellow business. Moreover, I have it from authority of equal standing and importance in the College with "J.A.," that the London candidate will, in the end, on the score, I presume, of unsatisfactory "professional qualification," be compelled to undergo an examination, just as at present, without the "grace" even of being allowed to pay the reduced fee (15*l.* 15s.). These are rather uncomfortable assurances, and not much calculated to encourage the expectations of those who have so long gone on waiting for the reform which was to enable them consistently to join the College of Physicians.

"J. A." is, I think, much too severe in his remarks on those gentlemen in practice as physicians who do not possess the College licence. Is it necessary to remind him how long it is since the College of Physicians was regarded as the great focus of everything exalted, learned, or respectable in physic, or how notoriously often it has been passed over and neglected by the Government and public in the most alarming sanitary crises? Are people to be blamed because they get careless about a connexion which had long ceased to be either any advantage or any very remarkable distinction?

The Charter in draft having been launched on the wide waters of professional opinion, I shall, I trust, be excused for

taking up so much of your valuable pages. Every gentleman eligible to the indulgencies promised therein will naturally feel anxious as to the real character of a measure which will eventually be the basis of a compulsory legislative enactment. In a recent Number of your Journal, you favoured the Profession with some editorial observations, in consequence, probably, of a communication direct from the College, on the scope of the Charter and intentions of those who got it up. I venture, therefore, to rely that you will not, in common fairness, delay assisting in the solution of the following questions:—

What sort of testimonial of professional qualification over and above the diploma ought to be expected by the most jealous and fastidious Censors' Board?

Whether it is commonly prudent to delegate to any set of men a discretionary power susceptible of such grievous misuse?

I am, &c. HENRY SAVAGE, M.D., F.R.C.S.E.

7, Gloucester-place, Portman-square.

HILL-TOP *VERSUS* VALLEY-BOTTOM WATER.

[To the Editor of the Medical Times and Gazette.]

SIR,—In corroboration of your leading article on this subject, I would mention the following curious fact:—

Llyncarrw is a lake at an elevation of about 1200 feet above the level of the sea, in the Breconshire range of hills. It, originally having no fish, was stocked by the owner about eighteen years since with trout taken from the river Clarwen, a stream separating Breconshire from Radnorshire, and which receives, besides other streams, the waters from this same lake. The trout, which are the only fish in the latter water, are edentulous, or (to use the words of my friend, Mr. Moggridge, upon whose authority I make the statement) have only rudiments of the teeth, whereas, in the Clarwen, these organs are finely developed; nor is this the only change they have undergone by being transferred from the "valley-bottom" to "hill top" water. In the former, the trout are "thin, white-fleshed, flabby, and poor eating;" whereas, those now taken in Llyncarrw are "pink as salmon, firm-fleshed, and good eating."

The marked difference of the same fish in the same waters under the two separate conditions, is very great, and strong in favour of your opinion of the greater healthfulness of the "hill-top" over the "river-bottom" water; for it is not beyond the limits of fair inference to assume, that the same causes which tend to debilitate the trout must act prejudicially upon the health of man.

I have recorded this fact before, in the "Notes on the Teeth," in the pages of the late *Gazette*; but the evident force which it bears upon the question of the relative purity of the "hill-top," when compared to the "valley-bottom" water is so great, that I thought you might not object to have your attention drawn to it.

I am, &c.,

Swansea. C. SPENCE BATE.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

JOHN BISHOP, ESQ., F.R.S., President, in the chair.

DISEASE OF HEART.—GENERAL ENLARGEMENT.—OLD PERICARDIAL ADHESIONS.—DILATATION OF ALL THE CARDIAC CAVITIES AND VESSELS.—FIBRINOUS DEPOSITS.

Mr. B. W. Richardson exhibited a specimen showing the above lesions. It was taken from a young girl 14 years old. Her mother had died suddenly from cardiac disease. Patient had been known to have an enlarged heart for at least four years past, for which no rheumatic or other cause could be assigned. Mr. Richardson first saw her on March 6, 1852. She was then suffering from slight rheumatic swellings in the joints, but previously had not complained. The heart-sounds were abnormal. The organ was evidently much enlarged, and seemed crippled in its movements. In three days the rheumatic symptoms had passed off, but the respiration had quickened, and there were signs of congestion in the right lung. To meet this, cautious leeching was employed, which temporarily gave relief. Up to the 16th, the symptoms did not much vary, but from that date to the 22nd they became greatly worse. The respirations often equalled 40 per minute; the pulse was quick, and exceedingly irregular. The heart's action was rapid and tumultuous, and a loud bruit was heard. The bowels which had before been sluggish, were inclined to be relaxed. On the morning of 22nd, she was suddenly seized with sensations of faintness. In the course of the day she rallied, and read a book with pleasure. In the evening, about nine o'clock, she raised herself to take a little toast and-water, and whilst in the act became very pale, exclaimed, "Oh, how weak I feel!" and laying herself back, instantly expired. In his remarks on this case, the narrator, after alluding to the possibility, that the dilatation of the cavities was caused by the pericardial adhesions, said, that four points were well deserving of attention, all of which had reference to the fibrinous concretions in the heart. First, it was quite obvious to any one who would look at the specimen, that the concretions there seen were direct and true depositions from the blood; that they did not arise from exudation; that there was, in fact, no trace of any endocardial lesion. Secondly, it was equally clear, that these concretions were formed during the life of the patient, and while the blood was circulating. Objections might be made to this, but if the real facts of the case were looked at, it was obvious, that no such concretions could form after the heart had ceased to beat, and to receive new supplies of blood. Let it be supposed, that the heart, at the moment of stoppage, was left with all its cavities full of blood, and that thus charged it should contain six fluid ounces of blood, which was an improbably large quantity; and then came the question, could any six ounces of blood deposit three fibinous concretions like those which were found in the heart now exhibited,—concretions which weighed collectively more than 200 grains; or was it likely that concretions deposited after death could so entwine themselves about the fibres and valves of the heart? It should be observed, that the concretions were three in number. One in the right auricle, which completely filled that cavity; another in the pulmonary artery at its root; and a third in the left ventricle; this last having so entwined itself with the mitral valves, that the faces of the two valves were actually brought close together by it, and were thus firmly bound. The concretions, then, were evidently formed some time before death. 3rdly. The cause, symptoms, and effects of these concretions. It must be borne in mind, that the patient in whose body they were found suffered in the first instance from a slight attack of acute rheumatism,—a disease always marked by an excess of fibrin in the blood. What, then, was more probable, than that this blood in passing over the elevated structures of the moving heart, left portions of the overplus of its fibrin upon those structures? To use a common illustration, the heart might be said to have churned the blood. With the symptoms arising from these concretions the author was now tolerably familiar. He knew, and asserted many days before death, that there were concretions in the heart now in question. He arrived at this conclusion, by taking into account the fact, that the disease (acute rheumatism,) with which the patient suffered at the commencement of the fatal attack, was one in which the fibrinous element is always increased; and he coupled this with the other symptoms—the tumultuous and irregular action of the heart, and the gradual failure of the circulation. The effects of such concretions were, he thought, sufficiently obvious. He believed that in this case, they and they alone were the cause of the death; indeed, the *post-mortem* examination showed no other lesion, except a degree of congestion in the right lung by no means sufficient to cause death, and evidently resulting from the cardiac obstruction. The heart was choked on one side, its valvular apparatus was prevented free play on the other, and death was the necessary result. 4thly. There was an interesting therapeutical fact connected with this case. In its treatment, the great object that was tried to be obtained was to bring the system under the influence of mercury. But this was never accomplished, although for sixteen days one grain of calomel, combined with a small quantity of opium, was given regularly every three hours; it seemed as though the effect of the medicine was met and effectually opposed by the state of the system. The author concluded, by observing, that in all inflammatory cases marked by great superfibrination, (such as peritonitis,) and which ended by what was called sinking, it would be interesting to learn how far similar concretions in the heart might be concerned in bringing about the sinking state.

Mr. Leonard read a paper on

PERFORATING ULCER IN THE STOMACH,

and in producing cases which had fallen under his care since 1825, observed, that as no disease was more insidious in its progress, nor more fatal in its result, so none was more deserving of patient investigation. Young persons in the prime of life, with health so slightly deranged that in most cases medical aid was unsought, were suddenly struck down, and it became obvious to the most uninitiated attendant, that death was at hand, and all that science could do was to attempt to mitigate the agonies of the sufferer. He did not produce these cases as examples of a rare disease; he had a higher object in view. He brought them before the Society that he might collect from its members their experiences of the previous symptoms of the disease which terminated in perforation; that a

correct diagnosis of its earliest stages might be formed, and the patient saved before the fatal extravasation took place. Conceiving this to be the true end and aim of the Society's meetings, he proceeded to state the cases. The first was that of Wm. Shepherd, aged 26, a stonemason. He was leaving the quarry at 6 p.m., when he suddenly laid his hand on his left side, uttered a groan, and fell. He found his countenance indicating extreme anxiety, with deadly pallor, lips livid, nostrils dilated, breathing short; pulse 130, small and thready; extremities cold, thirst urgent, knees drawn up, abdominal muscles tense, with violent pain diffused over the whole abdomen, but most acute in left hypochondrium; found no hernia, and last alvine excretion three days before. He diagnosed peritonitis, and opened a vein while yet on the temporary litter, but got only 12 oz. of blood; but on his arrival at home took 30 oz. more, and pulse rose slightly; applied a large vesicator, and gave castor-oil. Soon after this the man retched violently, but brought up nothing. Pain now increased rapidly, thirst intense, with dreadful restlessness. At 12 p.m., he took 20 oz. more blood; enemata were administered without effect. At 4 a.m. his pulse began to intermit, at 6 was imperceptible, and, while sitting up grasping the vessel for another drink, he fell back and expired. The *post-mortem* examination, 24 hours after death, showed him to be in good condition of body. On opening the abdomen, much gas escaped, and on four or five quarts of turbid fluid floated the castor-oil. Extreme vascularity of the peritoneum and omentum were present, and much fibrin was thrown out. On raising the lesser lobe of the liver, a neat round hole presented itself on the anterior surface of the stomach, which was thickened at the perforation. The other cases were so similar, with the exception of the thickening of the stomach, that we need not quote them. With one exception only they were all young females. The two last cases were the most important; the one, Henry Johnson, having been under the author's care from 3rd January to 18th March, 1850, the perforation being complete on the last-mentioned day, as the patient was swallowing a glass of gin. The other case had been an outpatient of King's College Hospital from 24th November to 2nd December, 1851, on which day perforation took place Mr. Leonard found, in Johnson's case, a cicatrix healed for about an inch and a half above the perforation, and from that and Recamier's case, entertained hope that the ulceration is capable of cure. He entered as minutely as these cases permitted into the symptoms upon which he would trust for diagnosis between this disease and dyspepsia and scirrhus of the pylorus. The principal symptoms were, large evolutions of gas from the affected organ, great irregularity in its power of chymification, showing greater or less appetite, great irritability, pain on reception of food, and more or less nausea and vomiting, the ejecta being often tinged or streaked with blood, the countenance and condition of body giving little indication of what is threatening; but, in the majority of cases, they were considered too slight for medical aid. He submitted, with much diffidence, the following tabular view:—

	Dyspepsia.	Scirrhus.	Perforating Ulcer.
Age generally ...	From about 25 years to 45.	From about 40 years upwards.	From 15 years to 50, but mostly in young subjects.
Sex	More males than females.	About equal.	More females than males.
Condition of Body	Spare, or soon brought to that state, but seldom emaciated.	Slowly loses flesh, and becomes emaciated.	Plump, and with all the appearance of health.
Abdomen.	Often tumid, with loud flatulence.	A tumour often felt somewhere between the sternum and umbilicus.	No appearances whatever.
Countenance ...	Not without colour, but that not naturally distributed.	Pallid.	Natural.
Pain	Not generally acute, and often referred to flatulence, and extending in the course of the duodenum, accompanied often with an enormous evolution of gas.	Severe, and very often acute, and referable to a point between the ensiform cartilage and the back, between the scapulæ, often excited by food, but irregular in the paroxysms.	Not so acute as in scirrhus, but is generally excited by the reception of food. Occasionally much flatulence.
Vomiting.	Of uncertain occurrence, generally referable to some kind of food taken.	Of uncertain occurrence, but when the paroxysm is severe, is produced by all food.	Not generally a symptom till after the ulcer seems to have formed, and then very frequent on taking food.
Heart	Palpitation, with dreams, and a train of nervous symptoms.	Palpitation, with fearful dreams, are common symptoms	No palpitation; no nervous affections.

He considers, however, these cases at present furnish too narrow a basis for practical purposes. The writers on this subject, viz., Drs. Abercrombie, Carmichael Smith, Crampton, Ebermaier, Routh, and Crisp, with Messrs. Gerard and Travers, were cited; and the members of the profession were earnestly requested to take notes of dyspeptic cases, as *post-mortem* examinations without the previous histories were of little use to science. Had Mr. Leonard been aware of perforation in Shepherd's case, he would not have poured castor-oil into the peritoneum, nor a friend of his have given brandy; but, in his subsequent cases, he administered no medicines but opium in pills to mitigate intense suffering.

EPIDEMIOLOGICAL SOCIETY.

Dr. Babington in the Chair.

The Secretary read the following Report:—

The Council, in presenting their second Report to the members of the Society, have much satisfaction in being enabled to congratulate them on the favourable progress made by the Society during the last twelve months.

Since the last annual meeting, the Society has continued steadily to increase the number of its members,—22 having been added to the list of contributing members, and 23 to that of the correspoonding members.

The Council, duly impressed with the importance of extending the inquiries of the Society to foreign and our own colonial possessions, as well as to the different countries of Europe, resolved to complete the list of Foreign and Colonial Secretaries as early as circumstances would permit. A Committee was accordingly established for that purpose, and the Council have now the pleasure of announcing the following appointments, viz.:—

FOREIGN AND COLONIAL SECRETARIES.

Belgium.—A. Sayer, M.D., 28, Upper Seymour-street, Portman-square.

East Indies—James Bird, M.D., 27, Hyde Park-square; and C. Finch, M.D., 58, Porchester-terrace, Bayswater.

France.—Waller Lewis, M.B., F.G.S., 18, Stratford-place, Cavendish-square.

Germany and Russia.—E. H. Sieveking, M.D., 3, Bentinck-street, Manchester-square; and W. E. Swaine, M.D., 6, Upper Seymour-street, Portman-square.

Greece and Italy.—C. R. Walsh, Esq., 42, Half-moon-street, Piccadilly.

Portugal and the Brazils.—J. O. M'William, M.D., F.R.S., R.N., 14, Trinity-square, Tower-hill.

Sweden, Norway, Denmark, and Iceland.—R. Gordon Latham, M.D., F.R.S., 27, Upper Southwick-street, Hyde Park.

West Indies.—Gavin Milroy, M.D., 30, Fitzroy-square.

The importance of these appointments is daily becoming more apparent. Letters have been received by the Foreign and Colonial Secretaries from various parts of the Continent, from India, and from the Brazils, expressive, on the part of our professional brethren and others in these countries, of their warm approbation of the objects of the Society, and of their willingness to co-operate with its members; and already some valuable contributions on subjects connected with epidemic diseases have been received from Sweden, from India, from the West Indies, and from the Brazils.

The Prussian Minister and the American Minister have each addressed a letter to the President of the Society, expressive of great interest in its objects, and offering in the most handsome manner to transmit letters and papers from the Society to the countries they respectively represent, and in other respects to aid the operations of the Society. There is also reason to believe, that similar facilities for holding communication with other countries will ere long be granted by the other foreign Embassies, and then the Society will be relieved from the heavy postage charges, which must otherwise be defrayed from its funds.

The Council, having deemed it would be conducive to the interests of the Society, that the first address to the Society by the President should be more extensively circulated among its members and the public, caused 1000 copies of this, as well as of the President's second address, to be printed and distributed accordingly.

The Reports from the Secretaries of the various Committees indicate, that their members are making steady and diligent progress in the investigation of the subjects with which they respectively have been entrusted.

The Small-pox and Vaccination Committee have already issued queries bearing on the subject of their inquiry to not less than 1800 medical men, of whom 527 have had the kindness to reply

more or less minutely to the questions of the Committee, and these replies have been tabulated, analyzed, and arranged.

The Committee have likewise put themselves in communication with the Poor-law Commissioners, with the Board of Health, and with the Registrar-General. These authorities have, with the greatest kindness and liberality, put every document in their possession at the disposal of the Committee, and a vast fund of important information has thus been obtained.

With the view of rendering the investigation as comprehensive as possible, the Committee have been induced to draw up another and very short form of queries, which they intend to address to all the Union medical officers (more than 3000 in number) throughout the kingdom. These queries the Poor-law Board have most kindly undertaken to forward free of expense. The same form will also be sent to various other medical men. The Committee, moreover, have already put themselves in communication, or are about to put themselves in communication with the authorities of the "National Vaccine Establishment," of the Small-pox Hospital, of the Royal Jennerian Institution, of the Army and Navy Medical Boards, and of various public institutions throughout the kingdom.

Besides their inquiries in this country, the Committee have sent, through the Hon. the Board of Directors of the East India Company, a certain number of their queries to medical men stationed in various parts of India, in reply to some of which a package of letters, containing much valuable information, reached the Society, from Bombay, by the last mail. They have sought and obtained direct information relative to the laws affecting vaccination, and the practice of it as pursued in Austria, in Prussia, and in Sweden. Within the last few days, a series of valuable papers has been received from Sweden, the statistics of which have been reduced to the form required for the Report of the Committee. The Royal ordnance and other papers in the Swedish language, on the same subject, are also being translated into English, through the kind agency of the Chevalier Tottie, Consul-General for Sweden and Norway.

Different members of the Committee have been engaged in examining various published works, Reports, and other documents on small-pox and vaccination.

From the great extent of the inquiry thus undertaken by them, —an extent, indeed, which has appeared to get constantly larger as the Committee have proceeded in their labours—it is impossible for them to say when they will be able to present a formal Report. The probability is, that they will avail themselves of the permission already granted by the Council, and present a series of Reports on the subject. But, whatever determination they may eventually come to on this point, they are sure that they will best consult the wishes of the Council, and act most in conformity with the high character and purpose of the Epidemiological Society by avoiding immature conclusions, and by steadily pursuing their investigations to the utmost extent to which they are capable of being carried with advantage.

As has been stated on a former occasion, the Committee appointed to inquire into the "Condition of Common Lodging-houses," etc., obtained a sufficient number of replies to the queries issued by them to enable them to present a Report, which is now in the hands of the Council. But the important measures which the Earl of Shaftesbury succeeded in carrying through both Houses of Parliament fortunately rendered the interposition of the Epidemiological Society, in a great degree, unnecessary. The working of Lord Shaftesbury's enactments will, however, continue to receive the attention of the Committe.

The Epizootic Committee, conducted by Professor Symonds, of the Royal Veterinary College, assisted by several distinguished members of the Veterinary and Medical Professions have held several meetings; but circumstances have hitherto prevented their making much progress in their operations. They, nevertheless, continue to receive assurance of valuable co-operation from various parts of the country; and the Honourable the Board of Customs have kindly directed their Inspector of Cattle to give the Committee such information as he may be enabled to afford regarding the diseases affecting foreign cattle imported into this country.

The Hospitals Committee.—This Committee appointed to inquire into the epidemic diseases prevailing in public hospitals, have completed their comprehensive form of queries, which is now being printed, and will be immediately circulated extensively among physicians and surgeons of the various hospitals throughout the kingdom, and others of the Profession, from whom information on the various subjects embraced by the Committee is likely to be obtained.

Among other Committees contemplated by the Council, it is intended to institute Committees to investigate scarlet fever, and other epidemics which affect the human race; likewise the potato-disease, and other diseases affecting the vegetable kingdom. But the formation of these Committees, as well as the successful carrying out of the objects of the Committees already existing, depend greatly upon the assistance which the Society may receive from the Profession and the public.

The Council are happy to announce, that several handsome pecuniary donations have been lately made to the Society, which will be more particularly noticed in the Report of the Finance Committee. They also gratefully acknowledge, that some valuable books have been presented to the Society since the last annual meeting.

To the Medical Press the thanks of the Council are eminently due, for the publicity they have uniformly given to the transactions at the Society's meetings,—more especially for the warmth with which they urged upon the Profession the necessity of their forwarding the objects of the Small-pox and Vaccination Committee.

The Council, then, in looking back upon the events of the Society, during the last twelve months, cannot but consider they have reason to be satisfied with its progress, and with the impression it has already made upon the general and professional public.

Judging from the additions that have been made to the numbers of the ordinary and corresponding members; from the papers that have been read at the ordinary meetings, as well as from the discussions that the reading of those papers have excited; from the extent to which the Society is gradually opening up communications with other countries, and from the manner in which its operations have all along been noticed and promoted by the public Press, and more recently by some from Government boards and the various representatives of foreign power in London, the Council feel themselves justified in anticipating that the Epidemiological Society is destined, at no distant period, to occupy an important position among scientific societies.

UNIVERSITY OF LONDON.

On Wednesday, a meeting of the Senate and other members of the University of London was held in the rooms of the Royal Society, Somerset-house, for the purpose of conferring degrees, honours, and prizes.

The Chancellor of the University (the Earl of Burlington) presided, and was supported on his right hand by the Vice-Chancellor (Mr. J. G. Shaw Lefevre), and Mr. George Grote. We were informed, that the following members of the Senate were also present:—Mr. Bacot, Dr. A. Billing, Professor Brande, Sir James Clark, Bart., Professor Faraday, Mr. Hallam, Sir S. L. Hammick, Bart. Dr. Hodgkin, Dr. Jerrard, Mr. Kiernan, Mr. G. C. Lewis, and Mr. Ridout.

The names of the candidates who have obtained honours, scholarships, exhibitions, medals, and prizes, in 1851, are as follow—we select those appertaining to the Medical Profession:—

DOCTOR OF MEDICINE.

Growse, R., Guy's Hospital—Gold medal for a Commentary on a case in medicine.

BACHELOR OF MEDICINE.

Honours in Physiology and Comparative Anatomy.

Reynolds, J. R., University College, University medical scholar and medalist.
Moocktoo, D. H., King's College, medalist.
Odling, W., Guy's Hospital.
Head, E. A. H., King's College.

Honours in Surgery.

Head, E. A. H., King's Coll., University medical scholar and medalist.
Thompson, H., University College, medalist.
Reynolds, J. R., University College.
May, G., King's College.
Stocker, J. S., Guy's Hospital.

Honours in Medicine.

Reynolds, J. R., University College, University medical scholar and medalist.
Thompson, H., University College, medalist.
Head, E. A. H., King's College.
Stocker, J. S., Guy's Hospital.

Honours in Midwifery.

Thompson, H., University College.

Honours in Chemistry.

Roberts, W., University College, prizeman.
Lambert, H. S., Queen's College, Birmingham.

Honours in Animal Physiology.

Roberts, W., University College, prizeman.
Buchanan, G., University College.
Fry, E., University College.
Beddoe, J., University College.
Oats, H. C., University College.
Rae, J., University College.

Honours in Vegetable Physiology and Structural Botany.

Buchanan, G., University College, } Equal.
Roberts, W., University College, }

FIRST EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE.

Honours in Anatomy and Physiology.

Hillier, T., University College, exhibitioner and medalist.
Tunzelmann, J. W. de, University College, medalist.
Roberts, W., University College.
Ekin, J., University College.
Robbs, W. E., King's College.
Ramskill, J., Guy's Hospital.
Carter, H. V., St. George's Hospital,
Winter, J. N., Guy's Hospital.

Honours in Chemistry.

Roberts, W., University College, exhibitioner and medalist.
Ramskill, J., Guy's Hospital, medalist.
Hillier, T., University College.
Tuozelmann, J. W. de, University College.
Carter, H. V., St. George's Hospital.

Honours in Materia Medica and Pharmaceutical Chemistry.

Ramskill, J, Guy's Hospital, exhibitioner and medalist.
Tuozelmann, J.W. de, University College, medalist.
Hillier, T., University College.
Mushet, W. B., University College.
Winter, J. N., Guy's Hospital.
Ekin, J, University College.
Briggs, H., University College.
Roberts, W., University College.

Honours in Botany.

Tuozelmann, J. W. de, University College, medalist.
Hillier, T., University College.
Ramskill, J., Guy's Hospital.
Briggs, H, University College.
Winter, J. N., Guy's Hospital.

Honours in Chemistry.

Jones, W. P., University College, prizeman.
Bond, F. T., Queen's College, Birmingham.
Brown, T. E. B., Guy's Hospital.
Blackmore, S. H., University College.
Cattell, W., King's College } Equal.
Thorogood, J. C., University College }
Clapton, E., St. Thomas's Hospital.
Worsley, P. J., University College.
Wolston, C., Queen's College, Birmingham.

Honours in Botany.

Brown, T. E. B., Guy's Hospital, prizeman.
Bennett, A. W., University College.
Clapton, E., St. Thomas's Hospital.

Honours in Zoology.

Bond, F. T., Queen's College, Birmingham.
Wolston, C., Queen's College, Birmingham.
Thornton, J. H., King's College.

The following degrees were conferred :—

		Presented by
Salter, H. H., M.D., King's	. . .	Prof. Miller, M.D.
Growse, R.		
Habershon, St. O.,	M.D., Guy's Hospital .	Dr. Addison.
Hicks, J. B.,		
Hassall, A. H., M.D., R. Coll. Surg. in Ireland		Prof. Graham.
Herapath, W. B., M.D., Bristol, and Lon. Hos.		Prof. Graham.
Radcliffe, C. B., M.D., Leeds School of Med. .		Prof. Graham.
Leatham, E. A., M.A., University College .		Prof. Clough.
Jackson, E.,		
Reynolds, J. R.,	M.B., University College .	Prof. Graham.
Thompson, H.,		
Beale, L. S.,		
Griffith, S.,	M.B., King's College .	Prof. Miller, M.D.
Head, E. A. H.,		
Monckton, D. H.,		
Hunt, R.,		
Odling, W.,	M.B., Guy's Hospital . .	Dr. Addison.
Stocker, J. S.,		
Burchell, P. L., M.B., Westminster Hospital .		Dr. Basham.

A considerable number of names, besides those already given, were on the list for presentation to the Chancellor, but as the gentlemen to whom the names belonged did not answer to the call made upon them, of course they received no degree upon this occasion.

MEDICAL NEWS.

University of London.—The Graduates' Annual General Meeting, held at the Freemasons' Tavern, Great Queen-street, last Tuesday evening, Jacob Waley, Esq., M.A., presiding, was very numerously attended. The Chairman congratulated the meeting on the advantageous position which they had now reached, and expressed a hope, that their labours would speedily terminate with the desired success. He justified the course which had been pursued, and contended for the desirability of the object sought for. The Secretary read the Report, which congratulated the Graduates upon their now holding a position far in advance of any hitherto attained. "With respect to the franchise, the Committee have already succeeded in raising the claim of the Graduates to a position engaging the serious and favourable attention of influential Members of the House of Commons. They have also drawn up a statement of their case for the use of Members of both Houses, and the public generally. At no distant day, the Committee believes that success is certain; inasmuch as every fresh movement has improved the position of the Graduates, and increased the respect in which they are held by the public at large." (Loud cheers.) Dr John Storrar moved, and T. S. Osler, LL.B., seconded, the adoption of the Report. Dr. C. J. Foster, M.A., moved, and G. Jessel, Esq., M.A., seconded the following resolution.—"That this meeting earnestly trusts that the appointment by the Senate of the Committee of the 21st ult. will result, at no distant period, in the acceptance by the Senate of a Charter, incorporating the Graduates into the University, with power and privileges calculated to raise the status of the Graduates, and to benefit the University itself; and authorises the Committee to act in their best discretion during the year now ensuing, with reference to any plan that may be proposed for that purpose." An amendment was moved, suggesting the calling of a special meeting of the whole body of Graduates to take the provisions of the Charter into consideration. Only five hands were held up for the amendment, and the original resolution was carried amid loud applause. Resolutions were then carried, requesting the Committee to continue their exertions for the erection of the Graduates into a Parliamentary constituency, and also to amend the Law L., by giving the Committee power to appoint, as Corresponding Members, Graduates who may be residing in London, or within twenty miles of the Post-office.

A Proposal is before the House of Commons to exempt the University of London from the operation of the Charitable Trusts Bill.

Royal College of Surgeons.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 30th ult.:—

Banbury, Richard, Launceston, Cornwall.
Barnett, Richard, Belfast.
Bockett, William Charles, Walworth.
Costerton, Horatio, Weymouth, Dorsetshire.
Webb, William, Barton-under-Needwood, Staffordshire.
Whitby, Robert, Bedford-square.
Leeming, Robert Toulmin, Lancaster.
Jane, Warren, Chepstow, Monmouthshire.

At the same meeting of the Court, Mr. Charles Frederic Augustus Courtney passed his examination for Naval Surgeon. This gentleman had previously been admitted a member of the College, his diploma bearing date December 20, 1847.

Collegiate Election.—At the request of numerous correspondents requiring information as to the candidates next in rotation for seats in the Council of the Royal College of Surgeons, we subjoin the following gentlemen eligible for that distinction:—

Adams, John, St. Helen's-place.
Avery, John, Queen-street, May-fair.
Cock, Edward, St. Thomas's-street, Southwark.
Coulson, Wm., Frederick-place, Old Jewry. (Elected.)
Dover, Frederick, Kentish-town.
Farish, James, Lancaster-place.
Gulliver, George, F.R.S., Royal Horse Guards.
Hilton, John, F.R.S., New Broad-street.
Hobes, John, Southampton-row.
Lane, Samuel Armstrong, Grosvenor-place.
M'Whinnie, Andrew M., New-bridge-street, Blackfriars.
Owen, Richard, F.R.S., Royal College of Surgeons.
Partridge, Richard, F.R.S., New-street, Spring-gardens.
Pennington, William, Montague-place.
Phillips, Benjamin, F.R.S., Wimpole-street.
Quain, Richard, F.R.S., Cavendish-square.
Shaw, Alexander, Henrietta-street, Cavendish-square.
Solly, Samuel, F.R.S., St. Helen's-place.
Tatum, Thomas, George-street, Hanover-square.
Tuson, Edward Wm., F.R.S, Harley-st., Cavendish-square.

Since writing the above, we find that the New Supplemental Charter, which it is expected will come into operation before the ensuing election in July, will, however, vitiate the order of precedence heretofore observed, as, under the provisions therein con-

tained, it will be competent for the friends of those "Fellows" hitherto passed over, again to propose them, as well as other younger Fellows, provided they have held that distinction for a sufficient period.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 29, 1852:—

BUTLER, GEORGE, Brighton.
DAVIES, JOHN EDWARD, Stone's-end, Southwark.
JOHNSON, HORACE EDWARD, Warwickshire.

NAVAL APPOINTMENTS.—Assistant-surgeon Godfrey J. A M'Cullagh (1844), to the Highflyer steam-sloop, at Portsmouth.

YEOMANRY APPOINTMENT.—1st West Yorkshire Yeomanry Cavalry, 3rd April, Robert Thomas Cooke, gent., to be Assistant-Surgeon, vice Square, resigned.

HER MAJESTY has been pleased to appoint Samuel Wall Jones, Esq., to be Colonial Surgeon for the Settlement on the Gold Coast.

CHARITY FOR HOSPITAL PURPOSES.—The Seamen's Hospital Society, which held their anniversary dinner lately, when a large amount was subscribed for the benefit of the institution, have announced the amount subscribed by different persons; among the rest,—Her Majesty, 105*l.*; the Emperor of Russia, 20*l*; the Lord High Admiral of Russia, 20*l.*; Trinity Corporation, thirty-first donation, 200*l.*; East India Company, twenty-ninth donation, 105*l.*; the Duke of Northumberland, 250*l.*; Baron Rothschild, 20*l.*; Trinity House, Hull, 25*l.*; John Pepys, Esq., fifteenth donation, 50*l.*; from Norwegian ships, per the Consulate, 50*l.* 13s. 4d.; per Messrs. Sack, Bremer, and Co., 45*l.* 9s. 6d.; from Swedish shipmasters, 21*l.*; from foreign shipmasters, 20*l.* 15s.; and these, with sundry 10*l.* 10s., 5*l.* 5s., 2*l.* 2s., etc., make up a total of 1359*l.*

KING'S COLLEGE.—The Annual Meeting of the proprietors of this institution was held lately, Lord Howe in the chair, when the Report of the Council was read, and was considered satisfactory. During the year, there were 199 medical pupils; the receipts from them being 4210*l.* 10s. 2d. During that time, the Rev. Dr. Warneford had presented 5000*l.* to the College for the foundation of several scholarships in the medical department. It was the intention of the Council, that the foundation-stone of the new Hospital should be laid on the 16th of June, after which every effort would be made to expedite the completion of the building. The Prizes were next distributed:—Anatomy, Palmer, J. W.; Physiology, Masters, M. T.; Chemistry, Palmer, J. W.; Practical Chemistry, Hulke, J. W.; Materia-Medica, Alexander, E. W.; Surgery, Hulke, J. W.; Medicine, Davis, M.; Midwifery, Masfen, W. E.; Botany, Masters, M. T.; Forensic Medicine, Hulke, J. W.; Comparative Anatomy, Partridge, S. B.; Medical Clinical (Winter), Cheatle, T. H.; Medical Clinical (Summer), Macanamara, F. N.; Surgical Clinical (Winter), Davis, M.; Surgical Clinical (Summer), Partridge, S. B.; Medical Society's Prize, Playne, A.; Leathe's Endowment, Liveing, E.; Warneford Endowment, 1st Prize, Macnamara, F. N.; 2nd Prize, Masfen, W. E.

UNIVERSITY COLLEGE, LONDON.—Distribution of Prizes, April 30, 1852.—Faculty of Medicine. Session 1851-52.—Medals and Prizes awarded:—Longridge prize, 40*l.*, for general proficiency (1851) to Joseph Lister, of Upton. Chemistry.—Professor Graham. Gold, William Price Jones, of Bala, North Wales; first silver, Frederick H. Robarts, of London; second silver, William Stanley Jevons, of London; (Birkbeck laboratory students) gold, Alfred Haslem, of Hertford; silver (equal), Arthur W. Wills, of Birmingham, and James Bell, of Armagh. Botany (1851).—Professor Lindley. Gold, Robert B. Smart, of Balshaw; silver, George Buchanan, of London. Anatomy.—Professor Ellis. Gold, John Z. Lawrence, of Hampstead; first silver, George Buchanan; second silver, Frederick T. Bond, of Truro; silver, junior class, John D. Scurrah, of Burnley. Pathological Anatomy (1851).—Professor Jenner. Gold, Joseph Lister; silver, F. W. Sayer, of Newport, Isle of Wight. Anatomy and Physiology.—Professor Sharpey. Gold, John Z. Lawrence; first silver, Fred. Wm. Sayer; second silver, James Turle, of Holloway. Medical Jurisprudence (1851).—Professor Carpenter. Prize (books), F. W. Sayer. Comparative Anatomy.—Professor Grant. Gold, John Turle, of Holloway. Materia Medica (1851).—Professor Garrod. Gold, Thomas Hillier, of Newmarket; first silver, William Mushet, of London; second silver, John Z. Lawrence. Surgery.—Professor Erichsen. Gold, William Roberts, of Bodedern, Anglesea; first silver, Arthur Dupuy, of Mauritius; second silver, Robert Grundy, of St. Helens. Midwifery (1851).—Professor Murphy. Gold, F. W. Sayer; first silver, James Turle; second silver, George Buchanan. Medicine.—Professor Walshe. Gold, St. John Edwards, of Bangor, North Wales; silver (equal), F. W. Sayer, and William Roberts. Fellowes' Clinical Medals.—Professor Parkes. Gold (1851), Joseph Lister; gold (1852), St. John Edwards.

THE LONDON HOSPITAL.—The One Hundred and Twelfth Anniversary Dinner took place at the London Tavern, on Thursday, April 29. His Royal Highness the Duke of Cambridge presided, and advocated the claims of the charity in a forcible and impressive manner. During the last ten years, 198,604 patients have been under treatment. Of this number, 75,474 were accidents brought to the hospital. At the termination of the entertainment it was announced by the treasurer, that 1807*l.* 8s. 6d. had been collected.

METROPOLITAN FREE HOSPITAL.—The anniversary festival of this Charity was held on Wednesday last, at the London Tavern, the Earl of Carlisle in the chair, supported by Sir E. N. Buxton, and the Messrs. Gurney, Fry, Rogers, and other eminent philanthropists. The cause of the Charity was ably advocated by the noble President, and many other gentlemen. Nearly 1600*l.* were collected for the general purposes of the Institution, and a large amount subscribed towards the building fund.

BETHLEM HOSPITAL.—At a special meeting of the Governors of this Hospital, held lately, it was recommended by the Committee in their Report, that there should be appointed a resident medical officer of a very superior order, who, with the present apothecary, should have the entire management and control of the patients and servants, and by devoting the whole of his time, should secure to the establishment a more perfect attention to the various cases under observation.

SCHOOL OF MEDICINE, ADJOINING ST. GEORGE'S HOSPITAL.—The distribution of prizes took place at this school on Saturday, May 1, at half-past two o'clock, Sir James Clark, Bart., in the chair. Before the ceremony of giving away the prizes, a report was read, from which we give the following extracts:—"Although the teachers have reason to congratulate themselves on the obvious general improvement manifested by the pupils in their devotion to their studies, they feel that some alteration might take place in the mode of recording the attendance of gentlemen on lectures in the schedules of the College of Surgeons and the Apothecaries' Society. In order that the attendance of each pupil on lectures may be fairly estimated, the lecturers of this school propose to enter in a book, kept by each lecturer for the purpose, the attendance of each pupil, and then, at the end of the course, to certify to the exact number of attendances. They feel confident, that in carrying out such a plan they will have the support of all the diligent students of their classes. After drawing attention to the importance of microscopical anatomy and chemistry, the Report says:—"It is only as the student bases his medical opinions upon a sound knowledge of the intimate structure of the tissues and chemical processes which go on in the human body, that he can be saved from the danger of falling a prey to the prevailing medical delusions,—delusions all the more dangerous, that they are countenanced by an ignorant public; and too often lead to those rewards which alone ought to be shared by the intelligent and honest practitioner. It is gratifying to the teachers of this school to be able to state, that they are not aware of a single instance of any gentlemen who have been educated here who have so far disgraced their Profession as publicly to practice homœopathy or its allied fashionable impositions. Before concluding the Report, it may perhaps be allowed to refer to the changes which are taking place in the medical corporations as causes of congratulation among the members of the Medical Profession. The new Charter to the College of Surgeons has removed much of heartburning and jealousy caused by the last; and the near prospect of a new Charter for the College of Physicians, by which that Institution may become a more active and useful body in the Profession, and instrumental in advancing its highest interests,—these are but the indications of a disposition on the part of the Legislature to regard with increasing interest a Profession, whose efforts for the public weal, if they do not stand first, do not at least stand second to any other. Never was there a time when the Medical Profession, by its knowledge of the laws of health and disease, could confer greater benefits upon mankind; and never was there a state of society in which the demands for the aid of the Medical Profession were greater. It rests with the Legislature to make those laws by which the rights of property shou'd not destroy the lives of the community, and to give free scope in every direction to the blessings which the Medical Profession has the power to confer." Prizes were presented in the several classes to the successful candidates:—Anatomy, Physiology, and Practical Anatomy: Gold medal, Mr. R. Benson; silver medal, Mr. T. Forder; certificate, Mr. F. Carter. Junior Anatomy (students of first session): Bronze medal, Mr. G. P.

Girdwood; certificates, Mr. F. E. Webb and Mr. E. E. Lloyd. Clinical Medicine: Certificate, Mr. A. T. H. Waters. Clinical Surgery: Prize, Mr. A. Umphelby. Practice of Medicine: Prize, Mr. A. T. H. Waters. Surgery: Prizes, Mr. A. Umphelby and Mr. R. Benson. Chemistry: Prize, Mr. G. P. Girdwood; certificate, Mr. E. E. Lloyd. Medical Jurisprudence: Prize, Mr. A. T. H. Waters; certificate, Mr. R. Benson. Botany: Prize, Mr. R. C. Hoile; certificates, Mr. C. Chapman and Mr. T. Forder. Practical Chemistry: Prize, Mr. Yorke H. Johnson; certificate, Mr. A. Garden. Midwifery: Senior prizes, Mr. R. Benson and Mr. A. T. H. Waters; junior prize, Mr. C. Chapman; certificate, Mr. R. C. Hoile. Materia Medica: Prize, Mr. E. Hall; certificates, Mr. T. Forder and Mr. R. C. Hoile.

Western Medical and Surgical Society of London.—At the annual meeting of this Society, on the 2nd of April, Dr. Robert Lee, F.R.S., President, in the chair, the Report of the Council (which gave a very favourable account of the state and prospects of the Society) was read, and the following members were unanimously elected office-bearers for the ensuing year:—President —G. A. Mantell, LL.D., F.R.S., F.G.S., etc., etc. Vice-Presidents —C. J. B. Aldis, M.D.; A. W. Barclay, M.D.; T. Cahill, M.D.; F. Godrich, Esq. Treasurer — G. Woolley, M.D. Council— W. Batten, Esq.; E. J. Bullock, Esq.; J. S. Christian, M.D.; — Cumming, M.D.; D. Davies, Esq.; W. Martyn, Esq.; W. C. Meates, Esq.; G. Sampson, Esq.; B. Smith, M.D.; R. Synnot, M.D.; D. Wane, M.D.; E. L. Webb, Esq. Honorary Secretaries—E. C. Seaton, M.D.; T. Keen, Esq.

Medical Benevolent College.—At a meeting of the Council, held in Hanover-square, on Tuesday, the 4th inst., the Right Hon. Earl Manvers, President, in the chair, the Right Rev. the Lord Bishop of Bangor was unanimously elected Vice-President. The cordial thanks of the meeting were voted to the Lord Bishop of St. Asaph, for his most excellent sermon preached in aid of the funds of the College, at the Holy Trinity, Brompton, on the 25th ult.; and the Rev. Mr. Irons was elected a Life Governor, for his kindness in granting the use of his pulpit on the occasion. The Treasurer's Report was most satisfactory for the last month.

Epidemiological Society.—A meeting of this Society was held, on Monday last, at the house of the Royal Medical and Chirurgical Society, Dr. James Bird in the chair. The meeting had been rendered special for the purpose of altering the law relating to members. Several new members were elected. An interesting paper on yellow fever, by Dr. Bascome, of Wyke-house, Brentford, was read by that gentleman, an abstract of which we shall probably lay before our readers. The paper announced to be read at the meeting in June is on small-pox and vaccination in India, by Dr. Finch.

The Sydenham Society.—The anniversary meeting of this Society was held at its apartments, on the 1st inst., Sir James Clark, M.D., President, in the chair. The Secretary having read the Report of the Council, the Treasurer, Dr. Babington, gave an account of the financial condition of the Society; in the course of which he stated, that in addition to a balance of 746*l.* 17s. 6d. in hand at the last meeting, and sundry sums paid in for the books of the past years, 1270 members had paid the annual subscription for 1852, the total amount being 2316*l.* 5s. 5d. Among the expenses, were editorial, 262*l.* 10s., printing, 776*l.* 7s. 6d., Secretary's salary, 157*l.* 10s., with sundry other payments. Balance in hand, 555*l.* The election for the next year took place, and the usual votes of thanks were passed.

The endowments of the munificent Dr. Warneford in behalf of Queen's College and Queen's Hospital, Birmingham, now exceed 25,000*l.*

Worcester General Infirmary.—The election of a house-surgeon, in the room of the late Mr. Cole, took place at the Worcester General Infirmary on the 3rd of May. Two candidates only (Mr. G. A. Sheppard and Mr. Erlin Clarke) went to the poll, both being natives of the "faithful city." The first-named gentleman was declared duly elected.

The Pharmacy Bill.—The Petition of the Medico-Ethical Society of Warrington, to the House of Commons, in Parliament assembled:—"Showeth, That your Petitioners are legally qualified medical practitioners in the town and neighbourhood of Warrington, and that they have examined a Bill now before your Honourable House, entitled, 'A Bill for Regulating the Qualifications of Pharmaceutical Chemists.' That your Petitioners are well convinced, that great evils have arisen from, that health is tampered with, and life lost, in consequence of the common practice of druggists prescribing over the counter, and visiting patients; and that if the Bill, in its present shape, becomes law, while the druggist will not in any way be better qualified to act as a medical practitioner, the new status given by the Bill will be the means of deceiving the people, and of aggravating the present evils indefinitely. That no provision is made to secure good and genuine drugs for the use of the public, as in the Apothecaries' Act, which contains clauses giving a right of search to the officers of the Society, with a power of destroying impure or adulterated drugs, and of fining persons having such in their possession; and your Petitioners submit, that if such clauses were necessary in the Apothecaries' Act, they are still more imperative in the Pharmacy Bill. That by another clause in the said Act, an apothecary substituting any drug for the one actually prescribed, is liable to fine and other penalties therein enumerated; but no such provision is contained in the present Bill. Your Petitioners, therefore, humbly request your Honourable House to adopt such measures as may be necessary for preserving the rights of the medical practitioner, for preventing the use of improper or adulterated drugs, for securing an accurate dispensing of all medicines, for protecting the health and lives of the people, and for avoiding those inconveniences which always arise from endowing Corporations with the powers of the Legislature. And your Petitioners will ever pray, etc. Signed on behalf of the Society."

Mr. Pascoe's Case.—The physicians and surgeons practising in the city of Rochester, and in the town of Chatham and the neighbourhood, have petitioned the Secretary of State for the Home Department on the case of Mr. Pascoe. The petition was despatched on the 3rd instant, and the prayer was as follows:—"That you would be pleased to direct, that a reconsideration be made of the evidence adduced at the trial of Mr. William Hamlyn Pascoe, to the intent, that should there be wanting evidence to show knowledge of pregnancy, on the part of Mr. Pascoe, at the period of his prescribing the oil of savine, he may be restored to liberty, inasmuch as the medical evidence supplied by Mr. Moorman is contrary to the experience of the Medical Profession generally."

Hayes *v.* Deakin.—This was a case heard lately in the Rolls Court, for an injunction to prevent the defendant from practising as a surgeon at Worksop, or within ten miles thereof, for the period of seven years. It appeared that the defendant, on becoming assistant to the plaintiff, agreed to give a bond undertaking not to practise in Worksop, or within ten miles thereof, for seven years after quitting plaintiff's employment; but the bond was never executed, only an agreement being entered into. The defendant pleaded, that, in signing the agreement, he had mistaken its tenor, supposing it to refer to some articles of partnership between himself and the plaintiff, and that he was ignorant of its real character. The Master refused the injunction, leaving to the plaintiff the right to bring an action, if so advised, making the costs costs in the cause.

Morpeth Board of Guardians.—At a special meeting of the Board, held on the 28th inst., the following important resolution towards extending the practice of vaccination was proposed by William Jobling, Esq., and seconded by James Hood, Esq., and carried:—"That all duly qualified surgeons in the union be appointed under the Vaccination Act to vaccinate all children in their private practices, and that they be paid the usual fee by the Board." This is a step in the proper direction, and we hope that other unions will follow the example of the Morpeth Board, and, by so doing, fully carry out the benevolent intentions of the immortal Jenner, and prevent the frightful ravages of small-pox. Owing to the unwearied exertions of Messrs. O'Connor and Hood, surgeons, the Guardians were furnished with accounts of unprotected cases of small-pox, and obstinate facts to strengthen the arguments in support of the cause they had taken up.

A wing of the Hospital Catolengo, at Bourg Dora, Piedmont, was involved in the ruin caused by the late explosion of the powder-magazine, and a number of the sick were, it is said, destroyed by its fall.

Mortality Notabilia.—In the week ending Saturday, May 1, the number of deaths registered in London was 1026, which is nearly the same as in the previous week. In the ten corresponding weeks of the years 1842-51 the average was 903, which, if raised in proportion to increase of population, becomes 993. Compared with the calculated amount, the mortality of last week exhibits an excess of 33; and hence it appears that though the public health has improved since March, it is not yet in so favourable a state as might be expected at this period of the year. In comparing the results of the last two weeks, it will be seen that there is again a slight increase in deaths referred to the principal pulmonary complaints, except consumption, those caused by bronchitis having risen from 71 to 86, those by pneumonia from 61 to 67, and the total of this class from 172 to 187, while

the corrected average of the ten weeks corresponding to last is 145. The zymotic class has also increased in the two weeks from 204 deaths to 232 (while the corrected average is 190), arising partly from scarlatina. This disease, which was fatal in the previous week to 38 children, numbered last week 45 cases, and prevails considerably at present; hooping-cough rose from 35 to 42.

DEATHS *in the Metropolis for the week ending Saturday, May* 1, 1852.

TO CORRESPONDENTS.

We have to intimate that, in future, all Communications for this Journal must be authenticated; gentlemen, therefore, who address us must favour us with their names,—certainly not for publication, but that we may be satisfied of their good faith. Henceforth, then, it is to be understood, that, when a letter is unnoticed, it is because the writer's card did not accompany it.

Gentlemen desiring personally to communicate with the Editor on the business of the Journal will find him, during the Summer Months, on Tuesdays, Wednesdays, and Thursdays, between the hours of 12 and 2, at the Office, 46, Princes-street, Soho.

It is again requested that communications shall not be otherwise addressed than

To the Editor,
"Medical Times and Gazette" Office,
46, Princes-street, Soho,
London.

Mr. Pascoe's Case.—Having last week intimated, that our correspondence on this subject was closed, we must decline inserting several letters we have since received. The matter has already been most thoroughly investigated, and is quite exhausted. Doubtless, we shall soon be able to announce that Mr. Pascoe has received the Royal pardon.

Terra Firma.—1. No. 2. No.

Mr. Jones, of Liverpool.—A letter addressed to the Secretary will elicit the information required.

A Subscriber, York.—Apply to the Hon. Secretaries of the Metropolitan Sanitary Association, 10, Craig's-court, Charing-cross.

[To the Editor of the Medical Times and Gazette.]

Sir,—This afternoon, a weak, delicate-looking man, who was in an extreme state of intoxication, came into my surgery, and demanded to be bled. I inquired into his case, but remonstrated with him, and told him that "if he would call on the morrow I would talk over the matter with him." He left, and went to a neighbouring practitioner, who bled him, for which he had to pay one shilling. Is it possible, Sir, that in our age a medical man can make blood-letting a matter of business, and take away 16 oz. of vital fluid from a man who had drowned his reasoning faculties with liquor? Are we to take the *ipse dixit* of a patient, that "he ought and must be bled," without inquiring into the case, more especially from on who has this delusion fostered on him by drink? Ought we not to practis from deduction? Such conduct as this ought to be repudiated by every well-thinking mind. It is dishonest to the Profession, but more dishonest to the poor patient. I am, &c. Frederic Robinson.
Bodmin, Cornwall.

A Young Practitioner.—Since the days of Diogenes, and long before, people have suffered from the canine teeth of their neighbours. A good remedy, as well as preventive, in many cases, is a soft tongue.

[To the Editor of the Medical Times and Gazette.]

Sir,—The fact of "No Irish need apply," is well exemplified in there having been no answer given to the queries, more than once inserted in your valuable Journal, respecting the admission of the children of Irish practitioners to the "Propert" College, the condition of such privilege being, of course, an equivalent amount of subscriptions from the members of the Profession in this country. It cannot have been, that the letters of your Correspondents on this subject have not met the eye of some of the Committee of the intended Institution. I am, &c.
Cork. A Father of a Family.

In reference to the above, we applied to Mr. Propert, and received the following reply:—

Sir,—I am desired to acknowledge the receipt of your favour of the 3rd inst., enclosing a communication from an anonymous Correspondent, and to forward to you, in reply, the accompanying copy of the Laws of the College, by which you will perceive, in Law I., that the benefits to be conferred are confined to medical men practising in England and Wales.

I have the honour to be, Sir, your most obedient servant,

To the Editor, &c. Herbert Williams, Assistant Secretary.

We have submitted Dr. Burt's case to an eminent accoucheur.

The disgusting Edinburgh mattrass affair shall receive its due consideration.

[To the Editor of the Medical Times and Gazette.]

Sir,—On looking over the "Medical Times and Gazette" of April 24, 1852, I found a case reported by Mr. S. W. Sibley, of "Dislocation of the Sternal end of the Clavicle backwards." The case is certainly very interesting; but Mr. Sibley says, "it still remains unexplained why a force applied to the middle of the bone sufficient to dislocate the sternal end, should not have caused fracture." If Mr. Sibley will turn to the 285th page of "Ward's Osteology," he will there find an account of some experiments made by Mr. Ward on the elasticity of the clavicle, and which I think will fully explain to him why a force applied to the middle of the bone sufficient to dislocate it need not *fracture* it. The account of these experiments is too long for transcription; but the inferences Mr. Ward deduces from them are the following, viz., "That the clavicle possesses sufficient longitudinal elastic force to throw its own weight nearly two feet on a level surface, and sufficient transverse elastic force opposite to the centre of its anterior convexity to raise its own weight about one foot vertically." Mr. Ward further says:—"The clavicle is endowed with this remarkable resiliency on account of the frequency and violence of the concussions to which it is exposed, and also on account of its importance as a support to the upper extremity, and a defence to the large vessels and nerves which lie immediately beneath it." Hoping you will excuse the length of this communication, as it is on an interesting and important subject, and trusting you will give it insertion in the pages of your valuable Journal,
I am, &c. A St. George's Student.
P.S.—I enclose my card.

A Well-wisher is thanked, but his communication is unauthenticated; besides, the subject, however important, is not suited for a strictly medical journal.

[To the Editor of the Medical Times and Gazette.]

Sir,—In a public hospital in another country the following disgraceful scene positively occurred not many months ago:—A Dutch sailor, master of a small trading smack, was admitted in a dying state; and, as a Lutheran, was anxious to see the Protestant clergyman; but, the country being Roman Catholic, a priest was likewise in constant attendance. So greatly was the former interrupted in his duties, that an appeal was made to the municipal authorities; but, while the affair was pending, the poor patient's last moments arrived. While unconscious and *in articulo*, extreme unction was administered to him, and he died, a portion of wafer being introduced between the lips, which had then lost the power of swallowing. He was claimed as a Roman Catholic, and his remains were carried off in triumph to the cemetery. Do we desire such scenes in England? Are we discontented with the enlightened forbearance, combined with the pious zeal, which characterises our own clergy? Let us not retrograde, by opening the doors of our valuable institutions to over-zealous youths, who fancy that good intentions can make up for real knowledge, and that the subject of religious instruction, all important and most comprehensive, can be grasped by a few hours' light reading, and the hasty formation of premature opinion. His voice only should be heard in an hospital whose life has been devoted to the interpretation of that Book in which we all believe.
I am, &c. M. B.

COMMUNICATIONS have been received from—

Mr. Robinson, of Bodmin; An Eleven Years' Subscriber; Secretaries of the Epidemiological Society; Dr. Turley, of Worcester; The Registrar-General; Secretary of the Royal Institution; Dr. Johnson, of King's College Hospital, and Woburn-square; Dr. Todd, of King's College, and Spring-gardens; Mr. Ludlow, of Paternoster-row; Terra Firma; Dr. Seaton, of Sloane-street; Mr. Jones, of Liverpool; A Subscriber, York; A Well-wisher; Mr. Robson, of Warrington; Dr. Brown, of Chatham; Mr. Spence Bate, of Swansea; Dr. Merryweather, of Whitby; Mr. Moorman, of St. Columb; Dr. J. G. Burt, of Lostwithiel; A Young Practitioner; An Edinburgh Friend.

Lectures on the German Mineral WATERS, and their Rational Employment. By SIGISMUND SUTRO, M.D., Senior Physician to the German Hospital, &c.

"To the medical practitioner these lectures will be found invaluable. They contain by far the best, most condensed, and most practical account of the German spas with which we are acquainted; moreover, they are written in a style which renders them agreeable reading."—Medical Times.

London: John W. Parker and Son, West Strand.

Just published, by Renshaw, 356, Strand, Second Edition, price 1s.,

Gilbert on the Extraction of Teeth; being a Work descriptive of a new and much less painful method of Operating, by means of Gilbert's Patent Fulcrum; the jaw cannot be fractured, or the gums lacerated; there is less danger of breaking the diseased tooth, and of hæmorrhage, &c.—Mr. Gilbert invites the Profession to inspect his invention, from 11 till 4, at 5, Suffolk-street, Pall-mall; or at the Manufacturer's, W. Matthews, 10, Portugal-street, Lincoln's-inn.

"We can confidently direct attention to it as a boon to the Profession and the public."—Lancet, Dec. 2.

"It allows of the extraction of teeth in the most scientific and easy manner; and, in performing certain other surgical operations, the chair will prove of inestimable value to the surgeon."—Medical Times, Feb. 10.

Just published, Second Edition, 8vo, cloth, 20s.; or, with Coloured Plates, 30s.,

On Diseases of the Urinary and Gene– RATIVE ORGANS (in Both Sexes). Part I. Non-Specific Diseases. Part II. Syphilis. By WILLIAM ACTON, late Surgeon to the Islington Dispensary.

"Mr. Acton's Work must be diligently studied by every practitioner who would desire to benefit, instead of injuring, his patient; it has a distinctive and pre-eminently diagnostic value."—Medical Gazette.

"The present edition of Mr. Acton's Work is very much enlarged, and contains a most valuable collection of matter."—The Lancet.

London: John Churchill, Princes-street, Soho.

Just published, in One Volume, 8vo, with many hundred Wood Engravings, price 50s. cloth,

Loudon's Encyclopædia of Gardening. Comprising the Theory and Practice of Horticulture, Floriculture, Arboriculture, and Landscape Gardening: Including all the latest Improvements, &c. A New Edition, Corrected and Improved by Mrs. LOUDON.

Also, in 8vo, price 31s. 6d., cloth,

LOUDON'S HORTUS BRITANNICUS; or, Catalogue of all the Plants Indigenous to, Cultivated in, or Introduced into Britain. New Edition, with a Supplement, and a New General Index to the whole Work. Edited by Mrs. LOUDON; assisted by W. H. BAXTER, Esq., and DAVID WOOSTER.

*** The New Supplement may be had separately, price 11s.

London: Longman, Brown, Green, and Longmans.

Now ready, 8vo, with 159 Wood-cuts, 10s. 6d.,

Lectures on Histology. Delivered at the Royal College of Surgeons of England. By JOHN QUEKETT, Author of "A Practical Treatise on the Use of the Microscope."

In 2 vols. 8vo, in 1, with Fifty Plates, containing Portraits, Plants, Facsimiles and Views of the Fortress of Lahore, price £1 11s. 6d.,

THIRTY-FIVE YEARS in the EAST: Adventures, Discovery, Experiments, Historical Sketches relating to the Punjab and Cashmere, in connexion with Medicine, Botany, and Pharmacy; together with an original Materia Medica and a Medical Vocabulary in four European and five Eastern Languages. By JOHN MARTIN HONIGBERGER, late Physician to the Court of Lahore.

Catalogue of Foreign Medical Books Gratis, on application, or per post, 6d.

Mineral Waters.—W. Best begs to inform the Nobility, Gentry, and the Faculty, that he has just RECEIVED a FRESH IMPORTATION of the under-mentioned MINERAL SPRINGS of Europe, comprising—Friedrich's Hall, Carlsbad, Marienbad, Homburg, Kissingen, Vichy, Seidlitz, Pullna, Ems, Seltzer, Faehingen, and Co., at his Eau-de-Cologne Arquebuzad and Foreign Mineral Water Depot, 22a, Henrietta-street, Cavendish square.—N.B. Balls and evening parties supplied with German and Struve's Artificial Seltzer Water at very moderate charges.

β QUININE, OR SULPHATE OF QUINIDINE,

A New Alkaloid discovered in the Cinchona Barks.—The attention of the Medical Profession is solicited to this new and important Alkaloid, as its medicinal effects are reported to be quite equal to the Sulphate of Quinine. It is more soluble in water, has the same crystalline appearance, and is much cheaper in price than sulphate of quinine.

May be obtained in any quantity of William Henry Cole and Co., Wholesale Chemists, 101, High Holborn, London.

Also, Quinoidine, Quinine, Cinchonine, Salicine, Tannin, Strychnia, Pure Creosote, Chloroform, Santonine, Ergotine, etc., etc.

Prices may be obtained on application.

COUNCIL MEDAL.—GREAT EXHIBITION OF 1851, CLASS XXVIII., No. 76.

To the Medical Profession.—Charles MACINTOSH and CO., 73, ALDERMANBURY, LONDON, and CAMBRIDGE-STREET, MANCHESTER, Patentees of the Vulcanized India Rubber, beg to draw the attention of the Medical Profession and the public generally to their DRAB VULCANIZED WATER PILLOWS and MATTRESSES, designed to alleviate the sufferings of bed-ridden patients and others. Price, from 10s. and upwards. Also, to the following, among many other articles of their manufacture. For particulars, refer to their Exhibition Catalogue, which may be had on application, gratis. Air-proof Beds and Mattresses, Hydrostatic Beds, India-Rubber Ring Beds, Bed-Sheets, Nursing Aprons, Sponging Baths, Chest Expanders, Breast Bottles, Truss Pads, Injection Bottles, Chemical Aprons, Sleeves, &c., Dissecting Gloves, Gas Bags, Elastic Woven Bandages, Belts, Stockings, &c. Tubing.

SOLICITORS.

Messrs. Bell, Steward, and Lloyd, 59, Lincoln's-inn-fields.

The "NEW EQUITABLE" embraces all the advantages of a strictly Mutual Office, with the addition of an ample subscribed capital, forming a *bonâ fide* security for its policy-holders.

POLICIES INDISPUTABLE.

The Policies of this Company being Indisputable they become as readily negociable, in monetary transactions, as any other description of personal property.

INVALID LIVES

Are assured at rates adapted to the circumstances of each case. Every circumstance affecting the health impartially considered.

DIVISION AND APPROPRIATION OF PROFITS.

The whole of the Profits will be Equitably divided annually amongst the holders of Policies issued on the Participating Scale.

MEDICAL PRACTITIONERS.

The Directors acknowledge and consult all duly-qualified Medical Referees as the Medical Advisers of the Company, and uniformly transmit, with the Questions intended to be made the basis of every Official Medical Report, A CONSULTATION FEE OF TWO GUINEAS.

EXTRACT FROM THE DIRECTORS' FIRST ANNUAL REPORT.

The extent and character of the business already transacted by the NEW EQUITABLE COMPANY have exceeded the most sanguine expectations of its founder and zealous advocates. From the 31st of January, 1851, the date of the complete registration of the Company, to the 31st of January, 1852, inclusive, no less than *four hundred and forty eight* proposals were received and entertained by the Directors. Out of this number of proposals *three hundred and fifty five* policies were completed, and the remaining *ninety-three* have been either declined, or are not completed. The sum assured on the *three hundred and fifty-five* policies issued by the Company is *One hundred and sixty-eight thousand seven hundred and sixty-five pounds*. The premiums on the policies thus effected amount to *Six thousand and twenty five pounds two shillings and sevenpence* per annum, the average amount of the policies being nearly *Fire hundred pounds*.

These facts afford matter for earnest congratulation to the Directors, the shareholders, and the assured. If the extent of the operations of the NEW EQUITABLE, during the past year, be compared with those of other Companies, it will be seen that there are very few of the oldest Life Offices, even of the first class, which have transacted an equal amount of business. It is demonstrated by the balance-sheets of offices in the best repute, as published from time to time, that after ten, twenty, or even thirty years of experience and consolidation, many of them have not equalled, in the year just ended, the infant labours of the NEW EQUITABLE.

Policies never disputed.

All descriptions of life assurance business transacted, and every facility given for payment of premium.

Prospectuses and further information may be had at the Chief Office, or of the Company's Agents.

Chief Offices—449, WEST STRAND, CHARING-CROSS, LONDON.

Rev. J. Lane, Saltash Parsonage,

PLYMOUTH, and many others, lately cured with the delicious and reasonable ALE, brewed with the water from "Harry Hill's Well." By tradition H. Hill was wonderfully cured in the 16th century by the water. *"Ergo bibas—iterumque bibas; mox conscia vitæ splendebit roseo picta colore genæ."*—B. HOLDEN, 55, Upper Seymour-street, Portman-square, sole London agent. H. Watts, Manager Stogumber, Taunton. One agent appointed to a town. October brewings are now in prime order.

Compound Wine of Sarsaparilla-root.

—FARRANT and FISHER, Earl-street, Finsbury-square, have lately added a highly important discovery to their already excellent mode of manufacturing TONIC WINES, in the process of administering the well-known Sarsaparilla-root in a more agreeable form than has been accomplished by others. It is now produced in the form of wine, and drunk as a daily beverage, being perfectly denuded of all woody matter, retaining all its desirable medicinal qualities, which render the root so valuable. Sold in pints at 1s., and quart bottles at 2s. each, by chemists, grocers, and tea-dealers. —Agents appointed:—Messrs. E. W. Allison, British Wine Vaults, 24, Crombie-row, Commercial-road East; Messrs. Edridge and Co., Grocers, 1, Oxford-street; Mr. J. R. Newton, Grocer, Melbourne-place, Old Kent-road; Mr. G. Painter, Tea-dealer, &c., 116, St. John-street-road; Samuel Pizzey, Tea-dealer, 22, Whitechapel-road; Wm. Ricket, Tea-dealer, 16, Mile End-road; Sands and Blackett, 49 and 50, High-street, Portland-road.

Medical Fixture and Glass Ware-

HOUSE.—WILLIAM KIDSTON and SON, 3, Liverpool-street, Bishopsgate-street, London, beg to inform gentlemen commencing or altering in the above Profession, that they have an extensive assortment of Medical, Shop, and Surgery Fittings, Glass, Eartheoware, &c., on view, of the most improved style and make. Plans and estimates for the entire fittings furnished. A large assortment of Second-hand Fittings always in Stock. Manufactory, Sidney-street, Mile-end-gate.

Allsopp's East India Pale and other

BURTON ALES.—The Public is respectfully informed, that the ALES of THIS SEASON'S BREWINGS are now ready for delivery, and may be obtained GENUINE, in Casks of Eighteen Gallons and upwards, either singly or in any quantity, at their respective Stores, as under, where also a list of the bottlers may be had. The Brewery, Burton-on-Trent; 61, King-William-street, City, London; Cook-street, Liverpool; High-street, Birmingham; the Exchange, Manchester; Royal Brewery, Dudley; 33, Virginia-street, Glasgow.

Medical Galvanism.—The most

efficient apparatus for the administration of Galvanism for the Cure of Disease, is the ELECTRO-GALVANIC MACHINE, which is the only Machine that possesses the qualities that are essential in a Medical Galvanic Apparatus, viz., that of affording a current of Galvanism in ONE direction only, which current possesses QUANTITY, and not merely INTENSITY.—Manufactured only by HORNE, THORNTHWAITE, and WOOD, 123 and 121, Newgate-street, London. Price £3 3s., £5s. 5s., £8 8s., and upwards.

To the Medical Profession.—The

attention of the Profession is respectfully invited to GLASS'S PURE WHITE GELATINE, recommended for making a first-rate Blanc-Mange, or Jelly, suitable for invalids, superior to Isinglass, having no fishy smell, and one half the price, in 6d. and 1s. packages. To be had, wholesale at the Steam Works, Brandon-street, Walworth; and at all respectable grocers and chemists in the country. Also retail in London of the following Agents—Petty and Wood, King William-street, City; Marshall and Co., 20, Strand; Back, grocer, 123, Tottenham-court-road; Graham, Ludgate-hill; Robert Ash, 211, Borough; Handford and Davies, 61, High Holborn.

Ventilating Boots and Shoes.—This

new and valuable discovery gives instant ease and comfort to the wearer, prevents Corns from throbbing, the Feet from swelling or being tender, and keeps them perfectly dry. The inventor solicits ONE TRIAL, feeling assured that, having ONCE experienced the comfort which they give, no person will wear any other. The medical Profession are respectfully invited to test the merits of this invention.

"In a sanitary point of view this invention is really valuable, and in warm climates it must be a great source of comfort to persons who are afflicted with tender feet."—The Lancet, Feb. 21, 1852.

To be had of the Patentee, C. MARSDEN, near the Bridge, Kingsland-road, London. By sending an old boot or shoe a fit will be guaranteed.

Shower and all Domestic Baths.—

Purchasers of these valuable and important family requisites should immediately inspect DEANE, DRAY, and CO'S EXTENSIVE STOCK, warranted the best manufactured, both for finish and durability. Deane, Dray, and Co.'s RECUMBENT SHOWER BATH forms at the same time an excellent Sponging Bath, and may also be used as a Hip Bath, thus affording to all the members of a family the various applications of the bath. Shower Baths of improved construction, Hip, Plunging, Sponging, Vapour, and other Baths, of various sizes and patteros. An illustrated pamphlet on Baths and Bathing, may be had on application, or free by post. —Established A.D. 1700.

DEANE, DRAY, and CO. (opening to the Monument), London-bridge.

James's Powder.—Physicians and

other Medical Practitioners having complained of the frequent use of Antimonial Powder, instead of the "Genuine James's Powder" prescribed, have represented to Messrs. Newbery, that the price of the powder has greatly led to this fraudulent practice, and has also greatly prevented the more general use of the powder. Messrs. Newbery have, therefore, yielded to the suggestions of the Profession, and have reduced the price; and, to secure the use of the genuine medicine, recommend that the same should be prescribed as prepared by Messrs. Newbery, thus—"Pulv. Jacobi Ver," (Newbery's.) The price for dispensing will henceforth be reduced from 21s. to 9s. an ounce. The genuine has the name "F. Newbery, 45, St. Paul's," engraved on the Government Stamp.

Bourjeaurd's Spiral Supporters.—

New Method of Compression for Varicose Veins, Corpulency, Umbilical Hernia, Spinal Weakness, and other cases indicating its necessity. BOURJEAURD'S SPIRAL SUPPORTERS are recommended by the most eminent of the Faculty as superseding every other contrivance hitherto invented. The Members of the Profession are respectfully invited to an inspection, and an explanation of their principle, by the Inventor, daily, between the hours of one and six p.m., at 10, Davies-street, Berkeley-square (opposite Mivart's Hotel).—Entrance at Private Door.

N.B.—It is necessary to caution the public against recent attempts to introduce, as Mr. Bourjeaurd's manufacture, articles imperfect in application and inferior in material, by surreptitiously copying his drawings and explanatory official circulars.

ORIGINAL LECTURES.

CLINICAL LECTURE

DELIVERED AT

King's College Hospital.

By ROBERT B. TODD, M.D., F.R.S.,
Physician to the Hospital.

ON THE TREATMENT OF PNEUMONIA.(a)

Gentlemen,—We have lately had some cases of pneumonia treated with a highly favourable result, upon a plan which differs materially from that usually laid down by some of our highest authorities in the practice of medicine. I propose, then, in my present lecture, to make two of these cases the basis of some remarks on the treatment of pneumonia, with a view to solving the problem,—what is the best mode of treating this disease; that is, what mode of treatment is best calculated to lead to a speedy resolution of the inflammation, with least injury to the patient's constitution, and with the shortest convalescence.

I will just observe, *in limine*, that the plan of treatment which I have pursued in the cases now convalescent, as well as in many others, consists, not in the use of remedies directly antiphlogistic (so-called), that is, of remedies intended directly to knock down inflammation by withdrawing blood, the supposed fuel of all inflammation, and by reducing vital power; but in the employment of means which will promote the free exercise of certain excretory functions by which the blood may be purified, and certain matters may be removed from the system, which, remaining in it, tend to keep up a state very favourable to inflammatory affections. The remedies to which I refer tend to promote the free action of the skin and of the kidneys, and in a less degree that of the intestinal mucous membrane; whilst, at the same time, a free stimulation is maintained of that part of the skin which is near the seat of the pulmonary inflammation; and an essential part of this treatment is, that while these remedies are being used, we do not aim at reducing the general powers of the system, but rather at upholding them by such frequent supplies of nourishment, easy of assimilation, as may be readily appropriated; and when necessary, even by the administration of stimulants,—on this principle, that the free exercise of two such great excretions as come from the skin and kidneys, would, if fed only from the tissues and the blood, (without the introduction of fresh supplies,) necessarily weaken and exhaust the general powers of the patient to an extent inconsistent with the full exercise of the process of repair needed by the inflamed organ.

Some physicians have drawn a distinction between cases of pneumonia, which is very useful with reference to treatment. There are, they say, two classes of cases of pneumonia: the one sthenic; the other asthenic and typhoid; the former capable of bearing the most active antiphlogistic treatment, and for which, indeed, they say, that that treatment is absolutely necessary; the latter requiring a supporting and even a stimulating plan, and for which an antiphlogistic plan would be extremely hazardous and dangerous. Now, while I fully recognise and admit the great practical value of such a distinction as this, I must remark, that it seems to me that it ought to be expressed differently. I would say, that all cases of pneumonia have, independently of this or that mode of treatment, a decided tendency to depress the general powers of life—some more—some less; and that, with all, a very decided direct antiphlogistic treatment is hazardous,—with some extremely so,—and that in none is it absolutely necessary; but, with others, there is no safety for the patient, unless the treatment from the beginning be of a decidedly supporting and stimulating nature.

You will note the distinction which I make between remedies *directly* and *indirectly* antiphlogistic. The former is a class of remedies whose supposed efficacy is founded upon a notion, (an erroneous one, as I think,) namely, that certain acute and sthenic inflammations are attended with an undue exaltation of the vital forces, both local and general, and that these must be depressed before the inflammation will yield. I say, I think this view erroneous, for while I would readily concede, that in pneumonia there is an exaltation of vital force at the inflamed part, it seems to me quite plain, from the clinical history of the malady, that the local inflammation draws so largely upon the rest of the system as to depress the general powers of life; else, whence the weakness, the exhaustion, the failure of appetite, the wasting, which take place in the course of the disease, even when favourable, independently of any particular line of treatment?

The remedies indirectly antiphlogistic are those by which it is professed to promote and exalt some particular functions, as sweating, or some other secretion, and thereby to purify the blood, by eliminating noxious matters through those channels, and by such purification of the blood to reduce or remove febrile symptoms.

The first of the two cases to which I shall refer to-day, is that of Edward Mills, aged 28, (Vol. XXXII., p. 88.) He is a railway porter,—a good specimen of a strong, athletic man, of active habits, and accustomed to hard work, and, at the same time, evidently a person who has been well fed. In short, he is a person just adapted, by constitution and habit, to bear antiphlogistic treatment, if such were necessary.

On the 3rd Jan., 1851, he was seized with shivering, headache, shortness of breath, and cough, soon followed by the occurrence of a sharp pain in the left side, particularly upon taking a deep breath, and all this accompanied by loss of appetite and fever. The next day he began to expectorate a quantity of very viscid and rusty mucus, and the breathing became more rapid, and the cough more frequent and troublesome; and on the 5th he came into the hospital.

The character of the sputa at once attracted our notice; and those of you who came round with me will recollect, that I particularly directed your attention to its extreme viscidity, and showed you how it adhered to the vessel in which it was received; so much so, that I could turn the pot upside down without the least displacement of its contents. We likewise observed the peculiar rusty colour of the sputa. The matter expectorated in such cases looks exactly as if it had been mixed with iron rust. The peculiar colour is caused by the admixture of a certain amount of the coloured particles of the blood, which may be seen in it through the microscope. The mixture is evidently very intimate; there is, in fact, in these cases, a hæmorrhage, doubtless from the naked vessels of the pulmonary air-cells. But the appearance and colour of the sputa differ very decidedly from those of the expectorated matter in ordinary cases of hæmoptysis. I think the difference is to be explained thus: In pneumonia, a copious secretion of mucus takes place from the membrane of the extreme bronchial tubes or bronchial passages; and, blood escaping from several very minute vessels, becomes intimately intermixed with the mucus, and gives it its rusty colour. The escape of blood and the secretion of mucus take place simultaneously, and in about equal proportions, and are dependent on the same cause, namely, that which irritates the lung. But in hæmoptysis the escape of blood is independent of any secretion of mucus, and often takes place without it, and the quantity of blood is always greatly in excess of that of mucus.

When present, this viscid and rusty state of sputa is a pathognomonic sign of pneumonia. Indeed, the great viscidity alone, even without any red colour, but with a yellowish bilious hue, ought always to excite our apprehension, lest pneumonia may be commencing. Passive congestion of lung, such as we may meet with in low fevers, or in heart disease, will, however, sometimes give rise to sputa not unlike those of pneumonia, but to be distinguished from them by their being less viscid, and containing more blood, which is much less intimately mixed with the mucus.

(a) Lect. XXX., delivered May, 1851.

Although the rusty and viscid character of the sputa will often enable us with certainty to diagnose the presence of inflammation of the substance of the lung, we must not conclude, that the absence of this characteristic expectoration is a positive proof against the existence of pneumonia. Many cases of pneumonia pass through all their stages, and resolution takes place, without the occurrence of any expectoration, or with that of a very trifling amount of colourless mucus. In the cases of typhoid pneumonia, it is not uncommon to find, that the patient does not expectorate, probably owing to his weak and sluggish state, his sensibilities being much blunted.

We found that our patient exhibited certain well-marked constitutional symptoms. He had a flushed face, and a hot and dry skin, and a tongue coated with a thick, white fur. He also complained much of thirst, and of a troublesome cough, and he suffered from a shooting pain in the left side below and a little in front of the scapula, and extending over the shoulder, which impeded his breathing, and was increased by deep inspiration. At the same time there was no very great increase in the quickness of pulse (it was 96), but the respirations were much more frequent than in health, being 36. The pulse was full and strong, and such as would have, not only justified, but invited bleeding, if we allowed ourselves to be influenced by that single symptom in adopting such a line of treatment.

A careful examination of the chest at once enabled us to determine the exact nature of the evil under which this patient was suffering. By percussion and auscultation we found a normal state of the right lung, the breathing being, however, rather more intense (puerile) than in health. On the left side, the percussion sound was quite natural in front, and good vesicular breathing was audible. Such, likewise, was the case all over the scapular region behind; but at the base of the left lung, all about the region to which he referred his pain, a decidedly dull sound was elicited by percussion. Now, this dulness of percussion may arise, as you know, either from an effusion of fluid between the pleural membranes, or from a thickened state of pleura, or from a condensation or such other alteration of the lung as prevents its free distension by air. When fluid is interposed between the pleuræ, the vibrations excited in the lung by the voice are not propagated to the wall of the chest, unless in cases where some old bands of adhesion serve to connect the surface of the lung to the costal pleura. In the present instance, the vibrations were sensible to the hand over the dull surface, and, therefore, we had to seek for some other cause for the dulness, besides pleuritic effusion.

There was no history of any former attack of pleurisy; therefore it was improbable that there could have been any thickened state of pleura. We found, however, a decided modification of the voice and breathing, which sufficiently accounted for the dull percussion. There were both bronchophony and bronchial breathing. Both these conditions occur only in a solidified state of lung; and when accompanied by viscid, rusty sputa, and the train of symptoms which we found in our patient Mills, we have no hesitation in referring the solidification to the effusion of plastic matter into the air-cells of the lung, which likewise serves to exclude the air from them.

The seat of the effusion of plastic matter in pneumonia is in the fine air-passages within the lobules of the lung, the inter-lobular passages being free. The air, therefore, in inspiration, rushes through these tubes; and the vibrations which it excites on the walls of the tubes are readily propagated by the solid lung to the surface, and thus the phenomenon of tubular or bronchial breathing is heard—a sound similar to that which one may cause by simply blowing into a tube, or of which you may get a natural example by applying the stethoscope over the larynx and trachea in the neck.

And in bronchophony, it is as if the vocal sounds were generated in the air-passages—the voice seems to come from the lung. The fact is, that the vibrations excited at the vocal cords in the larynx are propagated along the walls of the bronchial tubes; and, instead of being diffused through the soft, spongy lung, as in health, they are conducted in full force to the thoracic wall by its solidified portion.

You must not lose sight of the fact, that bronchial breathing and bronchophony are present whenever a part of the lung is solid, whatever be the cause of the solidification, provided only a great portion of the bronchial tube is pervious. Thus it is that we often find these signs when tubercular deposit has solidified a greater or less portion of lung. Sometimes pneumonia, running an insidious and chronic course, will make the lung solid, and develope these signs; or cancerous deposit may have been slowly taking place. To determine, then, the exact signification of these signs, you will have again to call in the aid of the history of the symptoms of the case.

You may have bronchial breathing when a slight pleuritic effusion has taken place; but such bronchial breathing will be accompanied, not with bronchophony, but with œgophony—a state of voice resonant and bronchial in its character, but rendered bleating by the interposition of a thin layer of fluid between the costal and pulmonary pleura. The existence of this modification of voice, and the simultaneous absence or great diminution of the usual vocal vibration, when the hand is applied closely to the wall of the chest, will distinguish the bronchial breathing which is accompanied by pleuritic effusion, from that which is due to the simple condensation of pneumonia.

Thus, then, the percussion which we first practised on making our physical examination of the chest directed us to the seat of the lesion; and from the bronchial breathing, the bronchophony, the rusty expectoration, the local pain, and embarrassed breathing, and the febrile disturbance, we diagnosed with confidence and certainty that the lower lobe of the right lung was in a state of inflammation, and had passed rapidly into hepatization. It is probable, too, that the inflammation of lung was accompanied by some degree of pleurisy. Of this, however, we had no certainty; but three circumstances rendered it probable; 1st, because the local pain was sharper than it usually is in pneumonia; 2ndly, because on one day the bronchophony was decidedly œgophonic in character; and, 3rdly, because pneumonia but rarely occurs without some degree of pleurisy affecting the pulmonary layer of the pleura.

The portion of lung involved in the inflammation was rather more than one-third of the posterior part—the inferior third; and the inflammation extended half-way, or possibly two-thirds forwards, towards the anterior surface of the lung. This was also the case in the second example of this disease which I shall bring before you to-day.

It is a remarkable feature in the clinical history of pneumonia, how prone it is to attack the lower part of the lung, and how much more frequently the posterior part is affected than the anterior, and how often the inflammation involves only a portion of one lung, and that portion not exceeding one-third or one-half, not often reaching to the anterior surface, and seldom extending to the entire lung. I know of no satisfactory explanation of its partiality for the posterior and inferior part. Perhaps dependence of position, as likely to affect the circulation, may have something to do with it. The extent of the inflammation, and, perhaps, in some degree, its position, ought always to be taken into account in forming a prognosis. If only a portion of one lobe is affected, recovery is much more frequent than the reverse, if the treatment has not been of a too depleting nature; should the whole of one lobe be involved, or more than half the lung, the chances of recovery are much diminished; and, should the inflammation engage the whole of one lung, the disease is very frequently fatal. When the pneumonia is seated in the upper lobes, the chances of recovery are much less than when it occupies the lower lobe. This is partly because when the disease attacks the upper lobe it is of a more asthenic nature, and partly also because this part is most apt to be affected in old persons. The clinical fact is highly deserving of your attention, and ought to exercise an influence upon your treatment.

Treatment.—Now, the treatment to which this patient, and the other whose case I shall presently detail, were subjected, consisted in the free application, to the back and side over the region of the dulness, of flannels soaked in warm spirits of turpentine, which were kept on for half an hour. These stupes were applied at three several periods of the day for the first three or four days. They excited considerable irritation and redness of the skin. At the same time a diaphoretic medicine was administered, consisting chiefly of the liquor ammoniæ citratis, of which as much as six drachms were given every three or four hours; at the same time an occasional dose of a mild aperient medicine was given, and the patient was allowed a pint of beef tea daily, with a little milk and bread.

Let us see, then, the progress of the case under this treatment.

The patient, you will remember, came in on the 5th of January, which, reckoning from the date of the first appearance of rigor and pain, was the third day of the disease.

On January 6, he was much the same as on his admission. Pulse, 96; respirations, 36.

On the 7th, a small patch of herpes was noticed at the right angle of the mouth. Pulse, 90; respirations, 36. A decided crepitation is heard at the end of each inspiration, although the breathing remains tubular; sputa abundant and less viscid.

On the 8th,—pulse, 80; respirations, 40;—the dulness, on percussion, less extensive; the returning crepitation is now audible over the whole of the region of inflamed lung; fever less; tongue cleaning; the pain in the side being troublesome, ten leeches were applied.

Jan. 9th, (seventh day of the disease).—The pain much relieved; bronchial breathing completely replaced by crepitation. Pulse, 96; respirations, 30.

On the 10th, the skin moist and soft; sputa no longer rusty; crepitation audible on deep inspiration, and the voice slightly resonant beneath the scapula. Pulse, 60; respirations, 32.

On the 12th, the crepitation being still present, a blister was applied to the side; and, on the 13th, it was reported that the breathing was nearly pure, crepitation having almost disappeared. Pulse, 68; respirations, 28.

On the 17th, fourteen days after the first seizure, our patient was quite convalescent.

Case 2.—The second case is that of a lad named Minns, aged 17, a waiter at a coffee-house. In his vocation he is a good deal exposed to cold, but his health has always been very good. His illness commenced on February 8th, with shivering, loss of appetite, cough, pain in the right side, and vomiting. In this case, the signs were of the same character as in the former, but were situated in the lower part of the right side. There was similar acceleration of pulse and breathing. The percussion was dull over the lower part of the right lung behind, where also there was a total absence of vocal vibration. In other parts of the chest the breathing was pure, and the percussion resonant.

Let me remark here, that, in watching cases of acute chest disease, it is very important to note the frequency of the pulse and respirations, as furnishing one of the most useful guides in the progress of the case; when matters do not go right, you find the frequency of pulse and breathing increase from day to day, or remain stationary; but if, on the other hand, you find a gradual fall in the frequency of the pulse and breathing, you may feel sure that your patient is making satisfactory progress.

These physiological signs are not inferior in importance to any afforded by the patient in the course of his malady; and you may even trust to them alone, when they take the favourable course, to assure you, in the first instance, that the disease is not extending itself, and afterwards, that the inflammation is being resolved.

The diagnosis of this second case differed from that of the first in this,—that, inasmuch as, in addition to the dulness on percussion, the usual vibrations excited by the voice were not felt when the hand was applied to the chest, there must have been fluid interposed between the lung and the pleura, to prevent their propagation to the walls of the chest; whence we concluded, that a slight pleuritic effusion accompanied the hepatisation of the lung.

The progress of this case, under the same treatment as that applied to the first, was equally satisfactory.

Thus, he came in on the 10th of February, on the third day of the disease; his pulse was then 118; his respirations, 38.

On the 11th, the pulse was 128; respirations, 34.

On the 12th, (the fifth day of the disease,) we find the pulse still high, 120; and respirations, 40. There was, however, a manifest improvement in the physical signs. The vocal vibration was now to be felt, showing that the pleuritic effusion had been absorbed. Slight crepitation began to be audible near the base.

On the 13th, the pulse had fallen to 96, but the respirations were still as high as 42.

On the 14th, the seventh day of the disease, the pulse had fallen still lower, and, what was more important, the frequency of the breathing was reduced to 32; crepitation was now distinctly audible over the whole of the diseased portion of lung.

On the 15th, the crepitation had become much larger and moister, and a good deal of vesicular breathing was audible at the lower part of the lung; and on the 17th, (the tenth day of the disease,) all traces of crepitation had disappeared, and the dulness, on percussion, had diminished; the pulse was 78, and respirations, 29.

Four days afterwards the patient left the hospital, quite restored to health.

Here, then, are two cases which I think you may take as examples of pneumonia, or, more correctly, of pleuro-pneumonia, of an average amount of severity. They were by no means of what is commonly called the asthenic or typhoid kind. The first, indeed, was distinctly sthenic; and the patient was a strong, athletic, muscular man, just such a one as you might bleed without much hesitation. The other patient was not of so vigorous a frame; but still, neither his constitution nor his symptoms were such as would have justified our regarding the case as asthenic.

Yet you will observe, that, in the first case, the inflammation was fairly undergoing resolution on the seventh day of the disease, and, on the eleventh day, the lung was in its natural condition; on the fourteenth day the patient was convalescent. In the second case, resolution was fairly established likewise on the seventh day of the disease, and on the fourth day of the treatment; and pure breathing was audible on the tenth day. A fortnight, likewise, was sufficient to restore this patient to complete convalescence. It is remarkable, that, in both cases, the resolution should have taken place on the same day of the disease; but then it must be noted that, in both, the treatment began on the same day, namely, the third from the seizure.

Now, I have brought these cases before you as good illustrations of the progress of the disease under a mode of treatment which I have found most successful in a considerable number of cases, both in hospital and private practice. This mode of treatment differs very considerably from that laid down by some of our best authorities as that which ought to be pursued in pneumonia. I have described in what that treatment consists. But I am quite prepared to hear it objected, that such a treatment is really doing nothing but leaving the disease to take its own course. Well, and if that course be to recovery in a short time, and at no expense to the powers of the patient, can we adopt any plan better suited to him? But I do not admit that the frequent application to the chest of such counter-irritants as mustard or turpentine, (three or four times a day,) and large doses of the acetate or citrate of ammonia, and occasional purging, exercise no influence, either upon the whole system or upon the local disorder. The drugs cause, undoubtedly,—and especially when the patient is kept in bed—free sweating or free diuresis, and often both; and it is quite consistent with all experience, that frequent counter-irritation exercises a beneficial influence on internal inflammations, and relieves pain. I prefer the frequent application of such stimulants as mustard and turpentine to that of blisters, as being quicker, and, on the whole, more efficacious and less weakening.

Now, in the particular cases under consideration, a manifest check to the advance of disease took place immediately the treatment was begun, and the signs of resolution followed very speedily; and I have already alluded to the curious fact, that the resolution in both cases was established on the same day of the disease, the treatment having likewise commenced on the same day,—a fact which seems very much to indicate that the treatment had a good deal to do with the early resolution of the inflammation.

Now, in estimating the value of this or that mode of treatment in any given disease, we should ascertain what are its natural tendencies—to recovery or to death. Is it a very fatal disease? When recovery takes place, what is the process? When death occurs, what are the immediate antecedents, and what its immediate causes?

These are points of clinical history, upon which our returns are, as yet, far from being complete or exact. The numerical returns which we have respecting this disease are unsatisfactory, because, in those returns, all cases of pneumonia, whether asthenic or otherwise, and whatever be the quantity of lung involved in the inflammation, are classed together. Suppose you were making inquiry respecting the results of treatment in cases of burns, how little information could you derive from numerical returns, if the cases were not classified according to the extent of surface involved in the burn! It is just so with pneumonia; we have as yet no classified re-

turns; but, looking to general experience and such numerical returns as we have, it may be stated, that, as in burns, pneumonia is fatal in proportion to the extent of pulmonary surface involved; but that, in the cases where one-fourth or a less portion of lung is inflamed, it has on the whole a very decided tendency to recovery. On the other hand, when all one lung is involved, or when a considerable extent of both lungs is engaged, the tendency is as decidedly to a fatal result.

The fatality of pneumonia, too, is very much influenced by the period at which the disease may have been detected, and some kind of medical treatment adopted. Thus, Grisolle's tables show that, when the cases were brought under treatment within the first three days, only 1-13th died; but if not brought in before the fourth day, 1-8th died; if on the seventh, 1-3rd; on the eighth, so large a proportion as ½ died. Age, likewise, exercises an important influence, and there can be no doubt that (excluding infancy, respecting which our facts are of the most unsatisfactory nature,) the mortality increases with the age; and at the advanced periods of life pneumonia must be regarded as a very fatal disease.

There are those who think, that when pneumonia affects the apex of the lung, it has a more fatal tendency than when it affects the base. I myself lean very much to this opinion, and because (without referring to complication with tubercles) in such cases, the disease is generally of the low or typhoid character; nay, under such circumstances, the pneumonia may be erratic, and, like erysipelas, pass from one to another part of the same lung.

It may, indeed, I think, be laid down, that in all these cases, the pneumonia has a fatal tendency in proportion as it tends to exhaust, whether by its extent or by the vital powers of the patient too readily succumbing, or by the exposure to cold, or by mental or bodily exertion during the early stages of the disease, or by some powerfully depressing influence connected with the original exciting cause of the disease.

But if you take cases of pneumonia occurring in persons in the full vigour of life, and not involving a very large portion of the lung, and coming under treatment early, we may regard it as a disease of not very fatal tendency, but rather very prone to get well when the vital powers of the patient have not been too much depressed; and such cases will get well whatever be the treatment early adopted, provided no great error has been committed in either direction —either in that of stimulating too freely, or of reducing too much. What we have to do in such cases is, to adopt the treatment which favours the shortest convalescence, and in the more severe cases we have to discover a mode of treatment which will promote the reparative process and uphold the powers of life.

The plan of treatment which has been recommended by some of our highest authorities, I need not tell you, is that by bleeding and tartar emetic. You bleed early from the arm, and if necessary you bleed a second or a third time; and if under this treatment resolution does not speedily take place, you bleed locally by leeches or by cupping, and likewise give tartar emetic more or less freely; to all which counter-irritation may be superadded in the more advanced stages.

I have had ample experience of this treatment; and I must confess, that that experience has so little satisfied me with it that I have for some years ceased to adopt it; for, under this treatment I have seen too many die; and when recovery has taken place, in too many instances has it been with a tedious, lengthened convalescence. Indeed, of all the fatal cases which it has fallen to my lot to witness, the great majority have been treated in this way; and in most of them antiphlogistic treatment had not been carried to an excessive or unreasonable extent.

In bleeding, the difficulty is to determine how much blood you may safely take away. Upon this point, I think all who view the matter candidly must acknowledge, that we have no satisfactory rule, notwithstanding the immense experience we have had of the practice. A loss of blood which scarcely makes an impression on one man will seriously reduce another; or a patient, who in a former illness has borne bleeding well, will suffer from it very much on a subsequent occasion; or losses of blood which were borne with impunity in one epidemic are injurious in another. All these are difficulties against which the greatest tact and judgment find it difficult to contend. And, although in particular cases relief may be afforded to certain symptoms by a timely bleeding, there is no doubt that in many it exercises no real influence in checking the progress of the disease; for, notwithstanding early bleeding, the lung becomes fully hepatized.

And as regards tartar emetic, I have long noticed, that patients do best when the drug neither sickens nor purges. On this subject, I am glad to fortify my own opinion, formed independently, by those of two such excellent authorities as the late Dr. Thomas Davies and Dr. Watson. Dr. Watson, alluding to Dr. Davies, says: "He states, and this is accordant with my own experience of the remedy, that the tartar emetic always acts best when it produces no effect except upon the inflammation itself; *i. e.*, when it does not cause vomiting, or purging, or a general depression of the powers of the system." When, indeed, you can insure your patient against these effects of the drug, it is a very safe and useful remedy in pneumonia; but the difficulty is to limit its action in this way. This may be done entirely as regards its depressing effects, by combining opium with it, and the combination often exercises a very good effect.

I had asked myself, why does this combination of tartar emetic and opium often tell so favourably in pneumonia? and the conclusion which I came to was this,—because it tends very decidedly to promote sweating, and perhaps other excretions; and I was thus led to try drugs of a like tendency, such as the liquor ammoniæ citratis or acetatis, in large and frequently-repeated doses, which do not exercise any depressing influence upon the patient. In pursuing the treatment, you must be careful to give full doses—six or eight drachms, and to repeat them every three or four hours; and you must diligently apply, two or three times a day, or more frequently, counter-stimulants over a large extent of the surface of the chest, such as mustard, or large flannels soaked in warm spirits of turpentine. With this you may often safely and with advantage combine the use of opium, with or without calomel; and now and then a mild aperient will be necessary.

Under this treatment, deaths from pneumonia have become extremely rare among my cases. The fatal cases are those of patients who come in far advanced in the disease, or in whom the disease has rapidly invaded a large surface of one or both lungs; but even such cases often do well under this treatment, combined with support and stimulants.

In all the cases, I am careful to give support from the first, in the shape of animal broths in small quantities, and at short intervals, and sometimes a small amount of stimulus.

In the decidedly typhoid cases, I need scarcely say, that the free use of stimulants is of essential service; and it is often of immense advantage to give quinine freely, the special indication for this latter drug being profuseness of sweating.

Pneumonia often comes on in connexion with rheumatic fever, or in a highly rheumatic or gouty diathesis. Such cases bear ill the bleeding and tartar emetic system, but are particularly well suited for this plan which I now recommend to you, and in them opium may be freely used with very great advantage.

I had almost forgotten to allude to a very interesting point which we observed in both these cases, viz., that during the stage of hepatization the chlorides had disappeared almost completely from the urine, but returned to it on the re-appearance of large crepitation, and on the resolution of the inflammation. This curious piece of chemical history was first pointed out by Redtenbacher, who records the results of his observations of it in eighty cases in a paper in *Hibra's Zeitschrift der K. K. Gesellshaft der Aerzte.*

I forbear from any further remarks on this subject, because my friend Dr. Beale is engaged in repeating the experiments, and with other observations on the chemistry of the sputa and of the blood in pneumonia, which, I have no doubt, will, ere long, furnish us with some very interesting results.(a)

(a) That I am not singular in feeling much dissatisfied with the bleeding and tartar emetic treatment in pneumonia, I infer from the fact, that this mode of treatment has been, as I am informed, quite given up at the great Clinical Hospital at Vienna. The curious paper of Varrentrapp, of Frankfort, in *Henle's Zeitschrift*, which I did not see till long after this lecture was delivered, indicates that that able physician had no particular liking for the treatment in question. Varrentrapp adopted the treatment of pneumonia by the frequent inhalation of chloroform in small quantity, but not to such an extent as to cause insensibility. The most frequent immediate effect of the treatment was perspiration and reduction in the frequency of the pulse. The results of the treatment appear to have been highly favourable. An able analysis of Varrentrapp's paper was published in the *Medical Times*, Vol. XXIV., 1851.

ORIGINAL COMMUNICATIONS.

PRACTICAL OBSERVATIONS ON DISEASES OF THE EAR.

WITH RECORDS OF CASES TREATED AT ST. MARK'S HOSPITAL, DUBLIN.

By W. R. WILDE, Esq., F.R.C.S., Etc.

(Continued from page 439.)

No. 20.—CONDYLOMA OF THE EXTERNAL MEATUS.

M. D. L., female, 25, a seamstress, suffers from deafness, tinnitus, occasional pain, fetid and sometimes bloody discharge from left ear for eight months; is otherwise healthy; attributes her affection to cold. The external meatus is completely closed by several condylomata which grow around its margin, but particularly from its lower edge. They are rather sensitive to the touch, lobulated on their surface, project a considerable distance beyond the margin of the aperture, and are a little more florid in colour than the natural skin. When the tragus is pressed backwards with the finger, a muco-purulent and offensive discharge exudes between these growths. It is not possible to insert even a small-sized speculum into the meatus without causing great pain and irritation. She could only hear the watch on touching. The right ear was normal. They were touched with the solid nitrate of silver, after which a poultice was applied. The subsequent treatment consisted in washing over the morbid growths with a strong solution of nitrate of silver every second or third day, and, in the intermediate time, keeping a dossil of fine lint, wet with diluted liquor plumbi, applied to the concha, besides the internal administration of Plummer's pill and sarsaparilla. By persisting in this treatment for upwards of two months, the condylomata disappeared, leaving the meatus natural, when the membrana tympani was found unimpaired, and the hearing was restored.

I have seen a case of cutaneous cancerous ulceration, extending from beneath the zygoma, which had quite eaten away the tragus, completely occluding the external meatus; but one of the most common causes of the disease are eczematous and herpetic eruptions, and chronic erysipelas, as detailed in the two subsequent cases.

No. 21.—ECZEMA AURIUM, THICKENING AND CLOSURE OF MEATUS AUDITORIUS EXTERNUS.

M. Q., female, 60, has been deaf, "off and on," for several years past, accompanied by noise and wandering pains in her head, with extreme itchiness in the auditory passages. The skin covering the auricle, and the scalp adjacent thereto, is of a fiery, red colour, speckled with patches of yellow, formed by the exudation which has collected in thin branny scales all over it. The parts are hot, and in some places sticky, from a thin ichorous matter which exudes from the surface. The auricle has lost its natural shape, its folds and sinuosities being partially obliterated, and it has become hard, thickened, and lumpy. The external auditory aperture has, owing to the disease extending into it, been lessened to a third of its natural size, and it is filled with a branny scurf. Upon removing the latter impediment, we can obtain but a very partial view of the membrana tympani, which appears to be thickened and opaque. Hearing distance, touching. The state of the parts are nearly the same on both sides.

In examining diseases of the external meatus and auditory tube, I find a small silver instrument, shaped like a blunt gorget, very useful.

Cases of this description, and, like this, of long standing, are very hard to manage, because there generally co-exists some constitutional taint, as shown in the cutaneous eruptions often manifest in other portions of the skin, and because the parts now under consideration have become so much altered in form and texture, that it requires a long course of treatment to restore them to their natural condition, and thereby re-establish their usual functions. The disease principally occurs in females of middle and advanced life; but it also happens to children from six to twelve years of age. In the latter, however, it is of a much more active nature, at the same time that it is much more amenable to treatment. In young persons the eruption often co-exists with scald head, and in both young and old, if the disease is allowed to exist for any length of time, it extends into the meatus, and even over the surface of the tympanal membrane, which it thickens and renders opaque. In old persons a collection of branny scales accumulates in the external tube. In young persons a thick creamy discharge will generally be seen coating over the lining of the tube and the external layer of the membrana tympani.

Cleanliness and attention are indispensable to the eradication of these affections. In the first instance, continual poulticing with any emollient substance which keeps up heat and moisture is necessary. Linseed meal, boiled bread and milk, or well-mashed turnips, will be found useful applications. Afterwards, when the extreme heat, swelling, vesication, and redness have subsided, a solution of the liquor plumbi, in the proportion of a drachm to the ounce, applied with several bits of fine lint, so as completely to envelope the auricle, and the evaporation prevented by covering over the whole with a piece of oiled silk or thin gutta percha, rarely fails to lessen the irritation and reduce the parts to a healthy condition. But while we employ these local measures, we must not neglect constitutional means. Strict attention to diet should be enforced; salt meats, savoury dishes, and pastry ought to be avoided, and a sufficient quantity of fresh vegetables should be consumed at dinner. After the patient has been well purged, a course of Plummer's pill may be prescribed with advantage—at least, five grains daily for an adult; and, in a little time, some of the preparations of sarsaparilla administered in lime water will hasten the cure, and assist to eradicate the disease from the system. This affection is very apt to relapse, and we should therefore continue both our local and constitutional remedies long after the inflammatory symptoms have subsided. Old ladies think they never can have a sufficient amount of warmth about their head, and it is very difficult to induce them to leave off even one flannel nightcap; but we should at least make the attempt, as the head and ear ought to be kept as cool as possible. As the swelling and inflammatory symptoms subside, we should again turn our attention to the state of the auditory tube. If any discharge exists, the meatus should be syringed gently with tepid water daily; and both it, the concha, and the tympanal membrane, washed over every second or third day with a solution of nitrate of silver of the strength of at least twelve grains to the ounce. Still more advanced in the progress of the treatment when the exudation has completely ceased and the thickened cuticle has been quite removed, much benefit will be derived from smearing over the tube and membrana tympani with brown citrine ointment every third or fourth day. This latter remedy, in which I have great faith in all diseases similar to that which we are now considering, should be made with either rape or cod-liver oil instead of the lard or butter usually directed in the Pharmacopœias. It is then of a much darker colour, and never becomes hard or crumbly. It should be applied in a melted state with a camel's-hair pencil, and diluted by about one-third of almond oil.

No. 22.—CHRONIC ERYSIPELAS OF AURICLE.

T. M., female, 52, has had frequent attacks of erysipelas of her head and face during the last five or six years. The effects of the disease are, however, now manifest only in the external ears, but more particularly the right. The auricle is not much enlarged, but has become hard, inflexible, and resembles a piece of wet, thick sole leather; its fossæ being apparently filled up by subcutaneous deposit. It is also somewhat shortened in its antero-posterior diameter. The skin is of a dusky brown colour without any exudations, eruptions, or crusts upon it, but to the feel it is lumpy and nodulated, like what we find in certain forms of elephantiasis. The lobe in particular presents this thickened appearance. The disease has extended some way in front of the site of the tragus, which is also thickened and lumpy. The meatus is nearly

closed. The treatment of this disease is very similar to that of the foregoing.

Dr. Kramer relates cases of scirrhous degeneration of the auricle, but it would appear that he has applied the term to cases similar to that now under consideration.

Enlargement of the sebaceous follicles in the concha frequently present in pale, cachectic persons labouring under aural diseases. They are easily recognized by their dark heads, and can be pressed out with a pair of forceps. Besides those eczematous eruptions, which I described in Case 21, many other cutaneous diseases affect the auricle, particularly in children. You are all aware of the excoriations which take place in infants behind the ears during dentition, and of the popular belief that they are salutary. Cleanliness is their chief cure when it is advisable to heal them up. We have a disease in Ireland so prevalent in some counties, that it would appear to be one of our national maladies—*pemphigus gangrenosis*, first described by the late Dr. Whitley Stokes, and of which I have given a description in the medical memoir attached to the Census of 1841. So fatal is this disease among children, that no less than 17,799 deaths have been attributed to it in ten years; and as it is a disease very well known to the lower orders, I am inclined to think that the amount has not been exaggerated. It goes under different local names, but the most common are "mortifying hive," "burnt hole," and "black ear;" the latter from its so frequently appearing behind the ears and upon the auricles. In the Irish it is styled *ithcheadh*, or the eating disorder, from its phagedænic character. The vesicles, or bullæ peculiar to this affection, generally leave an indelible irregular lace-like depression, similar to that of vaccination.

No. 23.—ANOMALOUS TUMOUR IN THE EXTERNAL MEATUS.

M. N., female, aged 47, has been deaf of the right ear for many years, and is much annoyed by itching and a stuffed feeling in the meatus. Upon inspection we find a tumour in shape, size, and colour resembling a half-ripe mulberry, occupying the anterior and lower edge of the meatus, and extending some way into the auditory tube, which it almost completely blocks up. It is not unlike that disease known here as button scurvy, and to which the late Dr. Wallace of this city gave the name of *morula*. It is attached by its broad base throughout its whole extent, and has neither enlarged nor extended for the last three years, during which time I have been in the habit of examining it occasionally. The patient never had otorrhœa, and there is no discharge now present, but occasionally the tumour becomes painful and irritable, and then its colour deepens from a florid red to a purple. It is now of a firm consistence, corrugated on its surface, and has a firm unyielding feel, quite unlike a nævus, for which at first sight it might be mistaken. I will not meddle with this tumour at present, as I once saw an affection very similar in appearance in a lady about this woman's time of life, end in frightful cancer, apparently from an endeavour to remove it by escharotics.

We meet with various other growths in the external meatus and auditory tube, independent of polypus or other morbid products, resulting from inflammation or its consequences. One of the most frequent of these is exostosis, of which I have seen very many examples. The projection generally grows from the posterior edge of the osseous portion of the tube, and slowly, but gradually, projects forwards, so as to leave but a slight crescent-shaped fissure between it and the anterior wall of the meatus. The integuments covering such growths are generally very smooth, white, and polished. I have never seen this disease affect both ears, but I have often remarked it in connexion with inflammatory affections both of the external tube and the membrana tympani. Autenrieth has given an account of one of these growths, and lately Mr. Toynbee communicated a valuable paper on the subject to the *Provincial Medical and Surgical Journal*. We had lately at the hospital a young woman in whom the external meatus was closed by a dense membrane, through which, when an incision was made, a probe introduced into the wound came in contact with the bone. As the patient had never heard on that side, and had never suffered from any aural disease in infancy, as well as from the circumstance of there being no bony meatus, we must consider that case as one of congenital defect, of which there are several similar examples on record. I have on two occasions, in private practice, seen a stricture of the auditory tube at the junction of the membrano-cartilaginous and osseous portions, in one instance so small as only to admit the round extremity of an ordinary dressing probe. Hardened cerumen having accumulated behind it, it was with great difficulty removed.

UPON THE CRANIAL BONES OF THE ANENCEPHALOUS FŒTUS.

WITH REMARKS UPON THEIR DEVELOPMENT.

By HOLMES COOTE, Esq., F.R.C.S.,
Demonstrator of Anatomy at St. Bartholomew's Hospital, &c.

The greater number of observations upon the developement of the bones of the skull are unconnected and devoid of system, having been compiled from examinations of the embryonic skeleton of the mammalia, without reference to any one primitive form or archetype. I doubt if the science of anatomy be advanced by such assertions as the following: "In the human embryo of the seventh month, Meckel has enumerated thirteen points of ossification to the os sphenoidale," etc. The construction of the skull admits of the indication of the essential vertebral elements of each bony ring with the same precision as do the segments of the spinal column; and the homological signification of each part remains unchanged, whether it be developed from one or from several points of ossification. The two ossa parietalia constitute a neural spine. Pre-eminently distinct in man, but united into a single piece in many carnivora, they do but repeat in the head the "spinous processes" of the vertebræ of the trunk. The spines of the hæmal arches are developed from pairs of the ossifying points arranged in linear series; their early coalescence to form the broad, flat sternum has given rise to the present erroneous idea of this piece of the skeleton, by which it is classed under the head of "flat bones." Each os temporis is composed of five bones—the mastoid, the squamous, the tympanic, the petrosal, and the styloid. The sphenoid is composed of ten bones—the basi-sphenoid, the two alæ majores, the pre-sphenoid, the two alæ minores, the two pterygoid bones, and the two cornua sphenoidalia.

"To the human anatomists," observes Professor Owen, "the question, What is a bone? may appear a very simple, if not a needless one. He will most probably reply, that a bone is any single piece of osseous matter entering into the composition of the adult skeleton; and agreeably with this definition, he will enumerate about 260 bones in the human skeleton. . . . The arbitrary character of the above-cited definition of a bone, and the essentially complex nature of many of the single bones, and independency of the processes of bones in anthropotomy, are taught by anatomy, properly so called, which reveals the true natural groups of bones, and the modifications of those which peculiarly characterise the human subject." (a)

It is in relation to the anatomy of the cranial bones that the skull of the anencephalous fœtus is particularly interesting. The terms "monsters," "monstrosities," etc., of such frequent occurrence in obstetrical works, should be banished from use; and this highly instructive though imperfect uterine production should be studied in its bearings upon the exact period of its existence, when the circumstances occurred which occasioned the retardation or the complete arrest of its developement. We have no more reason to believe that the anencephalous fœtus is primarily less perfectly formed than the subjects of club-foot and other similar malformation. The base of the skull supports the cell-structure, constituting the early fœtal encephalon; a membrane, corresponding with the dura mater, completes the neural arch. As the brain-vesicles, however, enlarge, it so happens that, from some cause—at present not decided whether it be a fault of primitive formation, intra-uterine mechanical violence, or both combined—they burst, discharge the fluid of the ventricles, together with the supra-ventricular nerve matter, and then the ruptured membranes cicatrise over the medulla oblongata, as a puckered loose bag.

From the moment of the accident, and it may occur at any period of intra-uterine life, the morphological developement of the cranial bones ceases. The different nodules and plates may, it is true, acquire some considerable increase in bulk; but they generally retain their individuality, and, in very great measure, the form which they possessed when

(a) Owen's Lectures on Comparative Anatomy, p. 36.

the brain vesicles were ruptured, and the encephalon ceased to exist. It follows, therefore, that, in the anencephalous fœtus, Nature has presented for our attentive study a series of specimens of human crania, illustrating the points of ossification at different periods of utero-gestation. We also possess the means, after accurate observations, of determining the period at which the rupture of the brain vesicles took place, by noticing the approach of the cranial pieces to the common known forms. I have before me the ossa sphenoidalia from two anencephalous skulls. In one, the basi-sphenoid is as distinct from the pre-sphenoid as it is from the basi-occipital. In the second the os sphenoidale very closely resembles the same piece in the adult skull. It is clear, that the process of ossification and of developement has gone on uninterruptedly longer in the latter than in the former specimen. We have reason to believe that the rupture of the brain vesicles, which led to the arrest of development, occurred far more early in the first specimen; and that, in the second, the rupture must have taken place after or at the time of the coalescence of the pre and basi-sphenoid, probably between the sixth and the seventh month of utero-gestation.

The occipital bone, in the anencephalous fœtus, usually consists of three pieces, of which the centrum or basi-occipital is well formed, and the neurapophyses or ex-occipitals perfect, except that at their superior extremity they are rounded off, instead of presenting a margin fit for coalescence with the spine or the supra-occipital, here usually entirely wanting.

The basi-occipital of an anencephalous fœtal skull, sent to me for examination by Mr. J. Reid, of Canterbury, presented the rounded thin edge of bone bounding the foramen magnum; the depressions for the recti-capitis-antici muscles; the tubercle for the attachment of the superior and the middle constrictors of the pharynx. The cranial surface was hollowed for the reception of the medulla oblongata. In the ex-occipital there was seen, well marked, the occipital condyle; the anterior condyloid foramen for the transmission of the hypoglossal nerve; the processus jugularis, or the transverse process for the attachment of the rectus capitis lateralis muscle, and a flat, thick, quadrilateral plate of bone bounding laterally the foramen magnum. But the foramina and the grooves for blood-vessels were all small, or entirely absent; there was no true posterior condyloid foramen, nor any groove for the inferior petrosal sinus. The foramen jugular was irregular and small. The supra-occipital was wanting, and with it all those important sinuses connected with the cerebral circulation, and meeting at the Torcular Herophili. The constant deficiency of the supra-occipital bone in these subjects, in whatever stage of advancement the other portions of the occipital vertebra may be, induces me to doubt the statement made by Meckel, that ossification of the os occipitis commences in the flat parts of the bone behind the foramen magnum by two triangular points of ossification, which soon fuse together, and are succeeded by two other ossifying points above them; and later still, two others at the side, and two more at the apex of the os occipitis. These "eight points of ossification" are too numerous; the explanation through their non-coalescence of the ossa Wormiana is unscientific and mechanical. As far as my own observations go, the bodies or the centra of the vertebræ are those parts which, about the second month, assume a definite character; the basi-occipital is no exception to this rule, it is the first to exist as a distinct part of the occipital vertebra, and is rapidly succeeded by the two ex-occipitals, which enclose in great part the foramen magnum. Although it is interesting to know where and how bony matter in these cases is first deposited, still it must not be forgotten, that the skeleton preserves its typical significations and importance, whether the phosphate of lime be present or absent. The basi-occipital is developed from a single central nucleus.

Each ex-occipital receives its bony matter by a nucleus which commences about the situation of the condyle and the anterior condyloid foramen: corresponding with the site of ossification of the neurapophyses trunk vertebræ. The supra-occipital, of later formation, and developed, not from cartilage as the preceding, but from membrane, commences, I believe, from one central radiating spot corresponding with the occipital protuberance.

I will not here enter into the subject of the developement of the scapula and coracoid process constituting the hæmal arch; the organs of circulation in the anencephalous fœtus are perfect; hence there is no deviation from the natural structure in the bones with which they are associated.

Meckel's assertion, that "the sphenoid bone is developed by sixteen, and the basilar bone by twenty-seven points of ossification is not supported by any examination, microscopic or otherwise. Were it granted (which, however, would in itself be an inaccuracy,) that exogenic processes of earthy matter possessed an importance equal to that of autogenic processes, and were worthy of enumeration, I doubt if we could succeed in making up forty-three points of ossification to the os spheno-occipitale. Valentin acknowledges that less is known of the developement of the sphenoid bone than of any other part of the cranium.—(Valentin's *Entwickelungsgeschichte*, s. 228.)

Although the ossification of the alæ majores is first most catching to the eye, whether, at the third month, according to Meckel, or the fourth month, according to Burdach; yet the assertion of Nicholai is essentially correct, that at the third month two single pieces (basi-sphenoid and pre-sphenoid, Owen) are developed, which speedily coalesce at the base of the cranium. In many an anencephalic skull, where the rupture of the brain-vesicles has occurred early, these two centra remain permanently distinct; but, in other instances, the coalescence is as complete as in the well-formed cranium. The alæ majores (neurapophyses) are single pieces; and I believe that those who have attributed to them many ossifying points, have not recognised exogenic processes of bone. They unite with the basi-sphenoid before the union of the orbito with the pre-sphenoid; but retain their individuality longer than the two centra or the basi and pre-sphenoid. In an anencephalic skull I have an os sphenoidale perfect in every respect, save that the alæ minores are unattached. Inasmuch as these parts become well formed at about the sixth month, and fusion with the centrum commences at the same period, we may conclude that this was the time at which, in the specimen here referred to, the rupture of the brain-vesicles occurred. The ossifying process commences by a single point around the foramen opticum.

The pterygoid bones, (*i. e.*, the internal plates of the pterygoid processes,) which are diverging appendages of the palate-bones, commence by a single centre of ossification, and exhibit, even at a late period, the clearly-marked line of union with the basi-sphenoid,—a coalescence by which the immobility of the upper jaw is maintained after the adaptation of the palate-bones to the pterygoid plates.

The double neural spines, which we recognise in human anatomy as the parietal and frontal bones, are developed by single ossific centres from each half, or, as would be commonly said, from each bone. Senff is probably more correct than Nicholai, when he assigns the twelfth week, rather than the ninth, for the first appearance of bone in this situation. In the anencephalic fœtus, both bones are the less perfect the earlier the rupture of the brain vesicles, and the more deformed the basis cranii; but I have never met with an instance in which they were better formed than the bones at the base, and they always have appeared less advanced in development. In one specimen, where not only were the bones at the base deformed, but many had lost all trace of their normal character, the parietal bones were represented by two thin scales of bone, about half an inch in length, and two or three lines in breadth; the frontal bones consisted only of the supra-orbital ridges.

The ossa nasi, of later ossification than the frontal bones, are formed by two lateral points, as the preceding; inasmuch as they are not included in the cranial vault, they are not subject to the same varieties in shape. The vomer, the perpendicular lamella of the ethmoid, with the olfactory-sense capsules, are usually well developed; but, in the anencephalous fœtus, longer than in the well-formed skull, the two laminæ of which the perpendicular lamella is composed, remain distinct, and the ethmoid bone, as in many of the carnivora, falls, when detached, into two distinct halves. Each half has two centres of ossification: one for each perpendicular lamella; a second for each mass of ethmoidal cells, which, however, in some specimens, remain cartilaginous so long, that they disappear upon maceration. The deeply-grooved vomer forms the centrum to this segment of the cranium. All authors agree in the late ossification of the ethmoid: Kerkring places it in the fifth month; Nesbitt, between the fourth and fifth; Senff, in the fourteenth week.

I do not, however, agree with Valentin, that the perpendicular lamellæ remains cartilaginous during the whole of uterine life. On the contrary, it becomes bony before birth, but the two laminæ of which it is composed (neurapophyses —Owen) often remain distinct.

That compound piece, first unravelled by Professor Owen, composed of five distinct bones, and termed, in human anatomy, the os temporis, is developed from five ossific centres. It is not sufficient to distinguish, with Valentin, 1. that part connected with the auditory apparatus, and, 2. the rest of the bone, but the latter portion must be yet further analysed. Two portions are not ossified till after birth, namely,—the mastoid and the styloid bones. The other three portions,—namely, the petrosal, the squamous, and the tympanic bones,—receive their first deposits of phosphate of lime about the end of the fourth month. The tympanic and the squamous bones coalesce in some skulls after the seventh month before birth; in others they remain distinct. The ossification of the auditory sense-capsule or the petrosal bone proceeds undisturbed by causes affecting the true cranial segments; and even in the worst-formed anencephalic skull, I have found the semicircular canals and cavities destined to receive the ultimate fibres of the acoustic nerve. There are many other instances in the history of the formation of the nervous system of early peripheral development. In an anencephalic skull I observed a curious deviation from the normal form. The left tympanic bone preserved many of its costal characters, and presented a diverging process, bearing a strong resemblance to the diverging appendage of the dorsal ribs of birds.

This process seemed to illustrate the law, that when, by some accident, the developing force is checked in its proper channel, it deviates and expends itself, not in the production of endless variety, but in the realisation of some known form peculiar to that element of the vertebrate segment. Thus information is to be acquired by the contemplation and study of "monstrosities."

There can be scarcely a more striking contrast than that between the anencephalic and the hydrocephalic skull. The moment the brain vesicles burst, ossification, in its morphological bearings, ceases; but the complete brain vesicles, however greatly distended, become covered by bony plates. The size which the parietal bones may attain in a cranium so diseased, may be seen by reference to any anatomical museum.

In the museum of St. Bartholomew's Hospital I have separated, arranged, and marked the bones in two anencephalic skulls. In one, the pieces are tolerably distinct: but in the other, the arrest of development, occurring at a very early period, has led to the fusion of the bones into several irregular masses, of which the analysis has not always been easy. It appears to me that this subject may be prosecuted with advantage. I am not aware of any previous successful attempt to name the cranial bones so arrested in development, the difficulty arising from the fact of their obvious deviation from commonly recognised forms.

The hæmal arches, or the bones of the face, and the hyoid bone are usually well formed, perhaps somewhat larger than natural, in the anencephalous cranium. The line of union of the pre-maxillary bone with the superior maxillary commonly remains quite well marked, although I have not yet examined a specimen in which the arrest of development was sufficient to constitute the well-known deformity called hare-lip.

SOME GENERAL OBSERVATIONS ON FATTY DEGENERATION.

By WILLIAM FREDERICK BARLOW, M.R.C.S.
Resident Medical Officer to the Westminster Hospital.

[Read partly before the Medical Society of London, March 20, 1852.]

The subject of degeneration is equal in a pathological, to that of nutrition in a physiological, point of view. If the latter shows us how we live, the former tells us why we die. But these phrases must be taken with due reserve, for our knowledge of the histories of life and death, at once so vast and complex, must, even could we pursue them with Bichât's genius, be for ever limited.

A short time ago, the topic which I shall venture to introduce this evening might have been comprised in a page, but now a large volume would fail to compass it; and I shall be only able to touch upon a few of its leading and most obvious points, as, greatly embarrassed by want of time, I coast too swiftly along its border.

One extremely common, and oftentimes fatal, form of degeneration is seen in the conversion of various tissues of the body into fat, which, although so liable to take their places, is quite incompetent to perform their parts. This change, deteriorating always, and leading frequently to gradual or sudden death, must be viewed in its widest and fullest relations, if we would know its applications and comprehend it aright. It must be judged of as a countenance, not by one feature separately taken, but by all its features, and their blended expression. It must be studied, not as to one organ simply, but the whole body; not as to local circumstances only, but general states; not as to old age merely, but all periods of being, even that previous to birth, the time of our "first life," as Mr. Hunter called it; not as to itself alone, but its frequent, and oftentimes most perilous complication of various affections. It must be pursued microscopically as a matter of course; but he who rests satisfied with the well-marked pictures of a few spoilt fibres or damaged vessels, has not a glimpse even of the field it occupies and its immeasurable relations to decay and death.

It may at once be stated, that the subject of atrophy cannot be separated from that of fatty degeneration; the causes of the one are those of the other, and both blending inextricably, form very often descending steps of one downward course; the first does not lead of necessity to the second, but the second frequently implies the first. nay, I think *always*, for although simple defect of nourishment and true degeneration, fatty or otherwise, are clearly to be distinguished from each other, it seems impossible to conceive how any part can ever be transformed into a lower material without first suffering an impairment of nutrition. But let it be noted, that the word *atrophy*, viewed in a strict and proper sense, and, indeed, according to its plainest meaning, does not simply imply an obvious wasting of the affected tissue, but also a deficiency of perfect nourishment, whatever be its kind, and must often be used, both as a matter of truth and convenience, in reference to those first failures of assimilation, which, if they neither stop nor be remedied, must lead sooner or later to manifest changes or losses of structure. Again, it is quite manifest that real atrophy and seeming hypertrophy of a part may co-exist; there is degeneration of tissue, but increase of size, bulk therefore often, without any corresponding power; and this we see excellently exemplified by hearts, which are at once fatty and enlarged; and it is also well instanced by what Mr. Hancock pointed out to the Society the other evening, in reference to that which used to be denominated hypertrophy of the bladder's contractile coat, this increase of size being really demonstrative of no augmentation of the muscular fibres, but often signifying the very contrary; for they have been seen by him in cases of such increase, and not faintly or a few times merely, more or less in a condition of fatty degeneration.

The right preface, then, to the rational study of fatty degeneration, is the consideration of imperfect nutrition; it then comes in legitimate order,—the order of nature, and is much simplified in consequence. In Mr. Paget's observations on atrophy, we find it treated of as a part of the subject; he speaks of it as a manifestation of atrophy, and so it is; there is no evidence of anything, if there be none of this.

It would be absurd to attempt, in such a fragment as I am offering now, an elaborate statement of all the causes (of *all*, indeed, under any circumstances) which may lead to fatty degeneration; but I will suggest for consideration some of the principal:—1st. A wrong or defective state and composition of the blood; 2nd. An insufficient supply of blood; 3rd. A deranged or obstructed influence of the nervous system; 4th. An imperfect, unhealthy, or declining state of the part to be nourished. (a) These conditions, be it observed, are in every respect the reverse of those which Mr. Paget has specified as most important, in order to the completion of perfect nutrition.

I. *A wrong or defective state and composition of the blood may be a cause of fatty degeneration.* The blood is the acknowledged life of all parts; its poverty, its dis-

(a) Lectures on Nutrition, Hypertrophy, and Atrophy, p. 8.

cases, its death are theirs. The great Harvey speaks of the blood being "the cause of youth and old age," and he who fairly studies this expression, shall, though he hold it too unqualified, at length perceive in it the largest meaning. When Simon informs us, that the blood of the fœtus contains more corpuscles than that of its mother; that the period of maturity is richer in these corpuscles than an earlier time; that they continue plentiful during middle age, but from thence are subject to decrease, does he not, in part, make a practical commentary on this indefinite, but suggestive phrase? (a) That the blood can give rise to fatty degeneration, in which shape age oftentimes comes prematurely, by diminishing the proper nutrition of the tissues, will appear from a multitude of familiar considerations.

Old age supplies us with by far the most abundant and general instances of this form of degeneration, a fact, which taken by itself alone, would almost prove to any one's satisfaction its dependence on a condition of atrophy or decline. Middle age may present the arcus senilis, (the discovery of the true nature whereof, by Mr. Canton, was a step in the inquiry of the first importance,) and youth even, nor do we yet know the earliest age at which it may appear; but, it is, generally speaking, seen at a later, feebler period, and constitutes one of its most characteristic signs. But to the fatty degeneration of extreme old age, which, doubtless, depends partly on the decreasing virtues of the blood itself, we can hardly affix the term abnormal or morbid; as well might we apply both or either of these epithets to the fading and falling of the leaves in autumn, which surely are not more out of the regular course of nature than were their budding and unfolding in the season of spring. Does the arcus senilis occur at this time, no one surely could speak of it as a mark of disease in the sense that he would of a variolous pustule. In the well-known representation of the seven ages the last is surely as natural as the first. But, physically and mentally speaking, the time of old age, or rather the state proper to it, is very capricious; and how can we wonder at this circumstance, seeing with what different constitutions men are born,—what varying hereditary influences affect them,—what unlike fortunes as to rest or labour, abundance or destitution, successes or failures, to say nothing of the effects of disease and accident, tend either to spin out or contract their career.

I believe that the symptoms of the "climacteric disease," as Sir Henry Halford has described it, (b) to be, not always, but in many cases, the evidences of that form of degenerations which occupies us. It is true, that he inclines to call it "a disease rather than a mere declension of strength, and decay of natural powers," but I dare to suggest, that the contrary view will be found more correct, and, above all, by those who most attentively consider his interesting history. Its occurrence between fifty and sixty-five years of age, a period embracing the grand climacteric, which Sir Thomas Browne discusses with all his wonted ingenuity and quaintness,(c) agrees well with the time wherein fatty degeneration invades very commonly to a serious degree. Sir Henry Halford speaks of its being complicated with other complaints; and this is exactly such a phrase as would be used by anybody about to describe the effects of fatty degeneration without clearly tracing them to their common source. He thinks it not very improbable, that it is connected with a brain wanting in energy, and a heart "irregularly supplied with nervous influence;" and these are signs of failure which, far from being incompatible with the state I would refer them to, are very often to be remarked as its attendants. "Physicians," he observes, "will not expect a cure for this malady;" neither will they for that severe and general degeneration which may occur at a time when no diet can restore the richness of the blood, no stimulants affect the vital organs as once they did, and no fortune, however prosperous or unexpected, arouse the mind from that increasing lethargy which it can no more successfully attempt to shake off than it can cure those physical changes of the brain whereupon the decline of its faculties depends.

In Dr. Marshall Hall's work on Diseases of Females will be found a chapter on "the Decline of the Vital Powers in Old Age." After reading his observations on the climacteric affection, I feel the more confirmed in these remarks. He speaks of a thinness and a paleness of the countenance, and a peculiar imbecility of its muscles; of debility of the articulation and the general movements; of headache and vertigo; of fluttering of the heart and irregularity of the pulse; of hurrying of the breathing by exertion or emotion; of quick fatigue; of wakefulness and restlessness; of a pale livid hue, and coldness of the fingers; of wasting of the muscular flesh; of the husky voice and clogged bronchia; of the distension of the bowels with flatus; of the patient being "obviously plunged into a state of dissolution by the too active operation of medicine." Let these symptoms be compared with those of the fatty heart, as stated by Dr. Quain;(a) and let those failures of function which degeneration produces be considered, together with the temporary disturbances which chlorosis and other affections of the blood produce; but, of course, there is all the difference between one organ failing from decay, and another, its structure remaining sound, flagging temporarily from insufficient stimulus.

But disease anticipates the ravages o time, and there is no more interesting part of our subject than that which refers to its wide relation to those various affections which impair nutrition. In Dr. Ormerod's observations on the fatty heart, we find accounts of its occurring in connexion with marasmus, epistaxis, phthisis, and fever, all which affections impoverish the blood.(b) That phthisis should lead to it can give no surprise; it runs often a slow and tedious course, while an emaciation, which shows the skeleton in outline, is but too common. The observations of Louis on the softening of the tissues in cases of this affection must be well considered in reference to fatty degeneration. What he says of the fatty liver, the softened brain,(c) the atheromatous aorta, and the condition of the heart, is of great interest; but the observations should be repeated with all the help which the microscope can furnish.

It must not be thought that this question of the complication of phthisis, by degeneration, has no practical interest. The fatty heart, when once produced, is a grave addition to a complaint not needing it; and may lead even to sudden death. Not long ago I examined a man far advanced in consumption, who, having a severely degenerated heart, turned suddenly pale and fell dead upon the floor; there was no act of dying, he was instantly dead. M. Louis, in his great work on phthisis, has a chapter on "cases of unexpected death, which are not explicable by the condition of the organs," and describes the case of a woman who "died suddenly, to the great surprise of the occupants of the neighbouring beds." "The heart was somewhat soft;" and there is no great boldness in conjecturing that it had undergone fatty conversion. M. Louis remarks, "No doubt, in this case, the amount of disease in the lungs was considerable; but a fair portion of those organs was still permeable to the air, and respiration performed with regularity a few minutes before death. Between that time and the moment at which life suddenly ceased, no change, at least of an appreciable kind, appears to have been effected in those organs. How, then, can we explain the unexpected death? Is it justifiable to compare the viscera with the locomotive muscles, and admit that, under certain circumstances, they become suddenly incapable of performing their functions from a kind of fatigue?"(d)

M. Bizot alludes to the fatty heart as an associate of phthisis, but the cases he refers to were not examined by the microscope; it can hardly be doubted, however, that there was extreme atrophy of the organ, if not absolute degeneration. Dr. Ormerod relates four cases of phthisis in which this change had indubitably happened; in one of these, however, the patient, as should be noted, had discharges of blood from the bowels during the last three months of his life.

It would be very important to examine carefully the

(b) On one form of fatty degeneration of the heart.—*Medical Gazette*, 1840.

(c) It would be very interesting to examine the small cerebral vessels in those cases of ramollissement which complicate phthisis; it can hardly be doubted that fatty degeneration would be found sometimes. Apoplexy is a rare complication of that affection, probably because of the circulation being so subdued and feeble. But M. Rochoux, in his well-known work, records a remarkable instance, entitled, "Ramollissement du cerveau avec melange d'epanchement de sang; phthisie pulmonaire." The case is rendered the more instructive from the patient being only 29 years of age. —"Recherches sur l'Apoplexie," p. 294.

(d) Dr. Walshe's Translation of Louis on Phthisis,—edition of the Sydenham Society, p. 397.

softened brains which occasionally occur in phthisical patients, with the view of detecting fatty degeneration of the small blood-vessels. The other day I visited a man, aged 40, who was dying of consumption; he had an arcus senilis and slight hemiplegia. His body was not permitted to be examined, and it remains uncertain whether his paralysis were due to the presence of tubercle, or fatty degeneration, or some other cause.

M. Louis, Dr. Latham,(a) and Dr. Stokes have observed upon the relation of the softened heart to continued fever. In some cases of its existence, an irregular, feeble pulse, and an almost inaudible systolic sound of the heart, have been noticed during lifetime. This matter is of great clinical interest. But how are we to tell whether this change of structure of the heart, supposing it to be detected after death, have preceded the fever, or occurred during its course? Much, perchance, may be learned from the history of the patient, who, ere he was fever-struck, may have long had symptoms of a fatty heart; much may be gathered from the period of the complaint whereat death surprised; much also from the age of the patient, and the absence or presence of the arcus senilis. Dr. Latham told me, that he had seen some sink at the beginning of fever, and in a manner not to be explained, unless by the degenerated condition of the heart. Dr. Ormerod mentions the case of a woman who died of fever, fatal by exhaustion; a fatty heart was detected after death; but as the patient was, previous to her illness, thin and haggard, and not less than 64 years of age, and lay no protracted time ill of her fever, it is fair to presume, that her cardiac malady had existed independently of the fatal affection, which it doubtless aggravated, and perhaps made mortal.

But all chronic or wasting diseases, whether external or internal, may lead to fatty degeneration. Among the cases referred to by Dr. Quain, is one of a child who, having been long ill, at last died of cancrum oris; another, of a young woman, who was the subject of chronic phthisis and gastric irritation; and a third was an instance of hæmaturia. Fatty degeneration, though sometimes noted especially in the heart, in which organ the change has been oftenest observed, is doubtless more general than many suppose. "We never hear," says Mr. Gulliver, "of fatty degeneration of the testicles, of the kidney, and other glands, of the lungs, of the blood, etc.; yet these affections are rather common in a variety of chronic diseases, especially of old people, and often in connexion with great general emaciation. In wasting of the testicle, and when the functions of that gland are impaired by lingering diseases or old age, the seminal tubes are more or less obstructed by fatty matter, which occurs in free globules, and in more equal-sized and minuter molecules, generally aggregated into comparatively large, rounded, or irregular masses, nearly opaque, and of a brown or dull yellowish colour."(b)

The microscopical researches of Mr. Bowman have lent new interest to the "fatty liver," by showing the real nature of the change. This organ degenerates from general atrophy, and so does the kidney. Renal degeneration, as Dr. Peacock(c) shows, not rarely co-exists with phthisis; nor can it be doubted that it is frequently occasioned by the latter affection, which, however, has no specific influence in causing it; whatever produces general atrophy may give rise also to failure of nutrition in the kidney, and consequent fatty degeneration. In old persons who have died apoplectic, I have noticed the granular kidney in combination with fatty degeneration of the large and small cerebral blood-vessels; forms both, of local atrophy produced by the general decline of age.(d)

(a) "I have been looking over M. Louis's admirable book upon fever, and find him laying great stress upon the intermitting and irregular pulse, attesting its formidable import, declaring how few who have it recover, and stating, that he has found in almost all of those who have had it, and have died, a softening of the heart's muscular structure."—Lectures on Diseases of the Heart. Vol. II., p. 163.

(b) In some testicles which Mr. Pardey (when house-surgeon to the Westminster Hospital) examined and showed to me, this kind of obstruction of the seminal tubes was extremely well-marked. See Gulliver on "Fatty Degeneration of the Arteries, with a Note on some other Fatty Degenerations." "Medico-Chirurgical Transactions," Vol. XXVI.

(c) *Lancet*, Vol. I., 1842.

(d) *Monthly Journal of Medical Science*, August, 1845. Dr. Handfield Jones made some interesting observations at a late meeting of the Society, (March 8, 1852,) in support of Dr. Prout's view of degeneration of the kidney, being, very frequently, quite independent of inflammation. Were I going into the general question of renal degeneration, I should, of course, refer particularly to the contributions of Dr. Johnson and Mr. Simon.

Much of early decay may be traced, doubtless, to the impairment of nutrition by slow disease; the malady vanishes, its effects never. Slow convalescence is a state which should be watched; the relapse of a malady is a frequent consequence of patients resuming their occupations too quickly; and the second attack is longer and severer often than the first. We must look more to the remote consequences of illness, and try to prevent them more. The young as to age become old as to structure, and often from affections which impair the blood. In the plant, which seems to grow as we view it, we have evidence of a sap loaded with nutriment, abundant to overflow, and freely circulating; but what inference draw we when the leaves turn yellow and fade away?

Close confinement has a wide relation to the question of atrophy. So have the ills of poverty, which untimely enrich pathological history. Bad food, foul air, and (far greater evil than it would seem at first) insufficient *light* even, lend death new powers. Quick starvation, as depicted by Dante, has made many shiver with horror; but *slow* starvation, silently working, but most constantly, effectually, and on an enormous scale, excites not nearly the sympathy that it should. It is this slow starvation which leads, not only to atrophy, but often to destruction of tissue; nor can we get frequently at its true history without a complex tracing of past miseries and deprivations. "Under whatever circumstances the fatty transformation occurs, it is obviously a process of degeneration, or degradation to a low scale of animal or even vegetable life." (a)

II. *An inadequate supply of appropriate blood* must be regarded as one of the principal causes of fatty degeneration. It may be either general or local. The questions of morbid change and simple deficiency of blood are, to a great extent, inseparable. Many of the cases already brought forward as illustrative of the one, imply also the other. Pure anæmia, speaking generally, can very rarely exist alone, for even that of hæmorrhage and blood-letting soon passes into spanæmia. (b) "Continuous and excessive loss of blood must necessarily produce a change in the composition of that portion which remains in the system." (c) F. Simon analysed the blood in a case of a melæna:—"It did not coagulate upon standing, and contained no fibrin. No blood corpuscles could be observed under the microscope, but merely some yellow particles floating in a clear fluid. It was very rich in fat and hæmaphæin." But its state here might have been due partly to the disease on which the loss of blood depended. As with a part, so with the body; it often doubly suffers from bad and scanty blood; and yet paleness, languor, palpitation, breathlessness, and frequent tendency to fainting, have, at times, not saved it from injurious depletion. F. Simon speaks of the difficulty of procuring blood from the spanæmic for analysis, on the ground of their being hurt by its withdrawal; but certain it is, that there are still practitioners who let not anæmia stand in the way of bloodletting.

Mr. Simon remarks, that, "in fifteen cases of idiopathic anæmia, Andral found the proportion of blood-corpuscles varying, by successive degrees, from what he considers their normal standard (127), to so low a level as 30 in a thousand; and he found (precisely as would have occurred after large hæmorrhages) that the water of the blood had increased just as the corpuscles had decreased, standing in one case as high as 886. In other particulars he considered the blood healthy; but his estimate of fibrin for healthy blood is so liberal, that probably most computators would have differed from him in respect of these cases, and would have described them as presenting an excess of that material; and the organic residue of the serum is in most cases high. It is, however, quite evident, from examination of the various analyses which have been made, that the increase of fibrin (though often observed) is not essential to constitute chlorosis; that the disease substantially consists in an atrophic condition of the blood, evinced in the non-development of its characteristic cells; and that the larger proportion of albumen generally found in connexion with this state may fairly be explained, where it exists, as an accidental result of the defective cell-growth, which has left

(a) Principles of Medicine, by Dr. Williams, p. 374. Researches have borne ample testimony to the truth of the observations on "Transformation and Degeneration of Textures" contained in this work.

(b) "From αἷμα, blood, and σπανός or σπάνιος, poor; poverty of the blood." Simon's Animal Chemistry, Vol. I., p. 306.

(c) Simon, Op. cit., p. 317.

the serum more saturated with organic blastematous material than it could have retained if the normal proportion of blood-cells had been developed out of it.

"Few of the effects of medicine are more immediate, or more remarkable, than that which results, in this disease, from the exhibition of iron. We all know, clinically, how soon, under the influence of this remedy, our patients recover their natural complexion; and a chemical analysis of the blood explains this sufficiently. F. Simon gives a case where, after a few weeks of treatment, the proportion of blood-corpuscles rose from 32 to 95 in the thousand; Herberger, one where it rose from 38 to 98; Andral and Gavarret, one where it rose (in spite of two bleedings) from 46 to 95. (a)

In all circumstances where death happens subsequently to repeated hæmorrhages or anæmia, the heart should be most minutely examined. Four examples of fatal chlorosis have been spoken of by Dr. Marshall Hall.(b) How important to have known the state of the heart-fibres!

I have already mentioned, in a former contribution, the case of a boy *six* years of age only, who lay long pale and languid before dying, and in whom, after death, the most marked degeneration of the heart was found. Dr. Ormerod has detailed the history of a pale, bloodless boy, aged *eight*, who had suffered from profuse epistaxis; he appeared to sink from exhaustion, and died in convulsions; the heart was found mottled by buff-coloured spots, composed of disorganised fibrils, which, in place of their proper striæ, presented "irregular rows of little granules of oily matter." A case was mentioned to me the other day, in which the arcus senilis was seen in a man aged forty, who had suffered from frequent nasal hæmorrhage, and had been bled largely likewise at different times. Without pretending to say positively that the arcus appeared as a direct consequence of the loss sustained in this particular instance, we may suppose with reason that the degeneration of the cornea may be much promoted by repeated hæmorrhage. The conversion of this part must be caused by atrophy, before the latter can be indicated by it. The frequent and often profuse hæmoptysis which occurs in phthisis must be considered in respect of the relations of this disease to fatty degeneration of the heart and other parts. Nor must the treatment of disease be passed over in reference to the production of atrophy and degeneration. Laennec relates, that the heart of a woman, fifty years of age, was found after death no larger than that of a child of twelve, and looked like a withered apple. She had been treated for hypertrophy on "the plan of Valsalva." I do not say the degeneration was fatty here; but the circumstance of hypertrophied hearts being likely to become converted into fat, reads, or should read, a lesson. So long as they are simply enlarged, life, though embarrassed, may be continued long; but if degeneration be added, the danger of sudden death may become extreme, and the peril is heightened, and that measurelessly, if bloodletting be largely and incautiously adopted.

The connexion of *sanguineous* apoplexy with *anæmia* remains to be traced. It is not to be doubted that the latter, when long-continued, may lead to fatty degeneration of the cerebral blood-vessels, just as it does to that of the heart-fibres. I have seen apoplexy happen in young subjects who looked deadly pale. Not long ago I examined a chlorotic young woman, aged 26, who died with extreme suddenness. There was an immense coagulum of blood in the middle lobe of the right side of the brain, and the part surrounding it was extremely soft. The case happened before I had read Mr. Paget's contribution, and the small blood-vessels of the organ were not examined. Dr. George Burrows has frequently observed apoplexy in pale, attenuated persons, having "the very reverse of the apoplectic make."(c) Dr. George Budd has narrated some cases of apoplexy consequent on syphilis.(d) The contribution is of great interest, as supporting the doctrine that all chronic and debilitating maladies *may* so impair the nutrition of the cerebral blood-vessels as to lead to their degeneration and rupture.

It may be well believed, that the study of the whole question of degeneration will have the best influence on the treatment of disease. Certainly we have too much closed our eyes on those organic conditions, which extremely loosen the tenure of life and too much modify the result of maladies, without our aiding them by that adventurous treatment which adds largely to the perils already existing.

[To be continued.]

SCIENTIFIC LECTURES.

TUESDAY, THURSDAY, AND SATURDAY, MAY 18, 20, AND 22.—ROYAL COLLEGE OF SURGEONS. *Subject*:—Professor PAGET, "On Malignant Tumours."

LIST OF SCIENTIFIC MEETINGS FOR THE WEEK.

This Evening,	May 15.	ROYAL INSTITUTION. *Subject*:—Prof. FARADAY, "On Points Connected with the Non-Metallic Elements." Three o'Clock.
——	——	MEDICAL SOCIETY OF LONDON. *Subject*:—Dr. W. V. PETTIGREW, "On Burns and their Treatment." Eight o'Clock.
Monday,	May 17.	ROYAL INSTITUTION. *Subject*:—J. CONOLLY, M.D., "On Insanity." Four o'Clock.
——	——	CHEMICAL SOCIETY. Eight o'Clock.
——	——	STATISTICAL SOCIETY. Eight o'Clock.
Tuesday,	May 18.	ROYAL INSTITUTION. *Subject*: — E. LANKESTER, M.D., "On the Physiology of Plants." Three o'Clock.
——	——	PATHOLOGICAL SOCIETY OF LONDON. *Meeting of Council.* Seven o'Clock.
Wednesday,	May 19.	ROYAL INSTITUTION. *Subject*:—J. CONOLLY, M.D., "On Insanity." Four o'Clock.
——	——	GEOLOGICAL SOCIETY. *Subjects*: — 1. J. TRIMMER, Esq., F.G.S., "On the Soils Covering the Chalk of Kent." 2. Sir C. LYELL, "On the Tertiaries of Belgium and their British Equivalents. Part II. The Lower Tertiaries." Half-past Eight o'Clock.
Thursday,	May 20.	ROYAL INSTITUTION. *Subject*: — R. WESTMACOTT, Esq., R.A., "On the History and Practice of Sculpture." Three o'Clock.
——	——	HARVEIAN SOCIETY. Eight o'Clock.
Friday,	May 21.	ROYAL INSTITUTION. *Subject*:—B. C. BRODIE, Esq., "On the Allotropic Changes of Certain Elements." Half-past Eight o'Clock.
Saturday,	May 22.	ROYAL INSTITUTION. *Subject*:—Prof. FARADAY, "On Points connected with the Non-Metallic Elements." Three o'Clock.
——	——	MEDICAL SOCIETY OF LONDON.—*Subject*:—Dr. SIBSON, F.R.S., "On the Use of the Chest-Measurer in the Diagnosis of Diseases of the Chest." Eight o'Clock.

Medical Times & Gazette.

SATURDAY, MAY 15.

THE LATEST EDINBURGH QUARREL.

VARIOUS pamphlets and letters, printed for "private circulation," and therefore read by everybody, have been travelling for the last two or three weeks among the gossiping circles of the Modern Athens. A very pretty quarrel between certain medical celebrities bids fair to divide Edinburgh into two parties, headed respectively by Professors Simpson and Miller, the two chief belligerents. The homœopaths have "improved the occasion," and Dr. Henderson grimly smiles over the feud he appears to have had no little share in exciting.

We, who are removed in every respect from the combatants, are perhaps in a better position to judge of this unfortunate business than those in the midst of the *mêlée*; and it is with the hope that our unbiased opinion may have some influence in leading matters towards an accommodation that we allude to the subject. Were it not for this consideration, we should hardly meddle with an affair so

offensive and disreputable, or give to it greater publicity than it has already unfortunately attained.

It appears, then, that in the middle of March, Dr. Simpson performed an operation on a lady, the wife of a medical man. We are not told the exact nature of the operation; it was not uterine, but, as we infer, vaginal. Two days subsequently, symptoms came on which were considered by Dr. Christison, who was called in, to indicate low peritonitis. The patient died before midnight on the same day.

So sudden a death, of course, caused no little noise in Edinburgh, where everybody seems much more concerned about other people's business than their own. It became the topic of the day, especially in medical circles; and, in the absence of any certain knowledge, all sorts of rumours were afloat. The most favourite opinion was, that the patient died of hæmorrhage. A certain circumstance gave colour to this. Dr. J. Matthews Duncan,—a quondam assistant to Professor Simpson, but with whom he had had some quarrel,—had employed an upholsterer and undertaker —one "Will Hardie"—to make some articles of furniture; and being in this man's shop, and conversing about the "engrossing topic," he was informed, that the mattress on which the patient lay had been sent, stained with blood, to the shop to be cleaned. Dr. Duncan mentioned this to Professor Miller. This latter gentleman, having subsequently, and according to his own solemn statement, accidentally, and for another purpose, entered the upholsterer's shop, took occasion to ask if the stain of blood was considerable, and was answered in the affirmative. Meeting subsequently with Dr. Henderson, who, in alluding to the great topic, mentioned the current opinion of hæmorrhage being the cause of death, Professor Miller stated the fact he had learnt from the upholsterer, as confirmatory of this opinion. In a short time, an homœopathic physician had circulated the news throughout Edinburgh, that a patient of Dr. Simpson's had been undoubtedly allowed to bleed to death after a trifling operation. On inquiry, this rumour was traced back to Professor Miller, having, as was supposed, originated from his conversation with Dr. Henderson. We may remark here, that this report of the bleeding was evidently altogether incorrect. Drs. Simpson and Christison are men of too great acuteness to have overlooked it had it occurred, to say nothing of the husband, a medical man, who watched his wife most carefully. On examination, also, of this famous mattress, the stain of blood was found to be very trifling, and not more than would naturally be found after any operation on a vascular part. It is much more probable, that the death was owing to one of those sudden sinkings after operation which occur from time to time without obvious cause, or that, as supposed by Dr. Christison, it was caused by low peritonitis.

Such are the facts of the case. The quarrel between Dr. Simpson and Mr. Miller arose from some expressions used by the former gentleman in a letter to Dr. Christison, accusing Mr. Miller of unhandsome and unprofessional conduct in making inquiries about the case, and in circulating the erroneous report. Mr. Miller's defence is, that the presumed fact about the mattress came to his knowledge accidentally, and that, in mentioning it to Dr. Henderson, in the course of a casual conversation, he had no sinister motive, nor wish to say anything injurious to Dr. Simpson.

Divesting the matter of all personalities, the thing lies in a nutshell. No one who knows anything about the gossip of a country town—and Edinburgh, in point of scandal, is equal to any country town—can doubt for a moment how far Mr. Miller has been to blame. In so far as he certainly was very curious about a thing which in no way concerned him, and kept no guard on a certain unruly member, he is to be condemned. His condescending to discuss the case with "Will Hardie," and the countenance he gives to the homœopaths—for he is the only man of mark in Edinburgh who notices or meets them—are much to be regretted. Professor Miller must remember, he cannot "touch pitch without being defiled." That he has done so, may have won for him the distrust of his brethren; but that, in the case before us, he has acted in any underhand manner, is certainly not warranted by the evidence which has been put into circulation. On the other hand, that Dr. Simpson should be annoyed at this false report, and hurt at the discovery, that the indiscretion or curiosity of a colleague had set it afloat, was inevitable.

It is possible, that some of those who read the correspondence may be disposed to take a less charitable view of matters, and may detect at the bottom of the business latent disunion and jealousy exploding in this miserable quarrel. Such a supposition would be so damnatory of the characters of some of the parties, that we cannot entertain it. It is also an unnecessary solution of the circumstances, since the real origin of the dispute is clear as daylight.

This dispute touches a vital doctrine of medical ethics; a doctrine admitted by all, but practised by few. The first law of courtesy and of professional honour is, that one medical man shall not discuss, criticise, much less condemn the conduct of another. How can the Edinburgh Professors expect that their students will practise, in after-life, those virtues of discretion, forbearance, and courtesy, which they see so utterly wanting in their teachers? How can Mr. A learn, that in practice he is to be under a deep moral obligation not to injure directly, or by inference, Mr. B, when he finds medical men in Edinburgh busying themselves about an unfortunate case, and giving currency to reports, the truth of which must be doubtful, though their injurious consequences to another medical man are unequivocal? Gross malpraxis and unavoidable mishaps are not to be put in the same category. The one may be visited with indignation; the other should be received with silence, or lightened by sympathy. The present quarrel between the two Edinburgh Professors has had its counter-part in every town in the kingdom, and in every case has arisen from the same causes, viz., a habit of gossiping, or a love of detraction. That such things can be altogether prevented, is perhaps impossible; yet we think, that the position in which these two eminent men have placed themselves, will go far to deter others from committing the faults which produce results so discreditable and humiliating.

BETHLEM.

At last, the massy portals of Bethlem have yielded. The Commissioners of Lunacy, upon the polite introduction of the Secretary of State, have visited its spacious and airy galleries, investigating and searching into the domestic management of that noble Institution.

For many reasons, we could have wished them a more pleasing visit; and desired that the result of their scrutiny should have led to the expression of approbation and gratification, rather than the merciless censure and graceless reproof which appear to have been visited upon the Medical Staff.

We feel, however, no hesitation in expressing our full conviction, that the publication of the particulars which led to this visit, and the details of the circumstances in which

neglect and incompetence have been observed, would remove no small portion of the blame from the shoulders of those upon whom it has unfortunately fallen, and transfer it to those who deserve it more,—the Sub-Committee of Governors.

Bethlem is only one of the many instances which from time to time have demonstrated the utter incompetence and unfitness of similar Boards of Management efficiently and properly to carry out the original intentions of the founders, and to administer with judgment and discretion the vast resources entrusted to them. In proof of this, how constantly are our law courts appealed to, and the talent of the bar engaged, merely to correct and unravel the confused and erroneous decisions, or the abuse of power by some wealthy trustee or guardian, whose only qualification for the position he holds is, the donation of some small portion of the accumulated gains of his successful speculations.

Were we to call over the list of Governors who take their seats at the various Board meetings at Bethlem, how many would answer solely to this qualification! how many would confess their entire ignorance in all matters pertaining to the insane, their treatment, and all that is requisite to their bodily comfort! And yet such men are the prime rulers in this charity, established solely to meliorate the condition of an unfortunate class of persons, whose management requires the wisest counsel, the most prudent vigilance, the nicest discrimination, and the soundest judgment, to superintend and direct. For this duty who so fitted as the well-educated and enlightened physician? But, if his hands be tied in the performance of his task, his practical usefulness limited, or his privilege of judgment curtailed; is it just, is it honest, to visit him with censure, and accuse him of neglect and inefficiency, caused solely by the bonds imposed upon him by others?

It has long been generally felt, and nowhere so much as in old endowed institutions like Bethlem, how little value or attention is paid by Governors to the opinions, suggestions, or advice of the medical officers, even in matters within their province. Committees and Sub-Committees are too fond of assuming to themselves all power and knowledge, forgetting the true spirit of the foundations whose trusts they are called upon to administer, and ignoring in their self-sufficiency all but their little selves. Of this, Bethlem has long been a glaring illustration; for it has been said, that there a medical officer may as well hope to be heard above the locomotive scream, as to obtain the adoption of any novel scientific principle, however beneficial he may deem it for the patients. Should his suggestion run counter to the opinion of the Committee, or interfere with the pet conception of some popular individual at the Board, such recommendation is passed by unheeded, and all chance of its adoption rendered hopeless.

It is to remedy this state of things, and reform the evils which of necessity result from them, rather than to inculpate the Medical Staff, that the Government has wisely interfered; and most sincerely do we hope, that they will continue to do so until Bethlem has been remodelled, and fitted with every means and appliance which science and experience can suggest to further the special object for which it was founded. Then, and not until then, will this Institution, noble and rich in every way, become what the public have a right to demand it should be—the foremost and the first asylum in the land, dispensing liberally and faithfully the great blessings it has the power to bestow; and a School of Medicine, from whose halls students may go forth, to carry through the length and breadth of the Kingdom a sound knowledge of the pathology and nature of insanity, and extended views of the rational treatment of the insane. And this, under the persuasive power of public opinion, it will become.

The fiat that reform shall take place, has gone forth. Already the old leaven has been quickened; gently stimulated by the Commissioners in Lunacy, it will soon work out. From a pamphlet before us, we find it is decided, that Bethlem shall have a resident Physician.

"The proper care of the patients, and the due administration of the Hospital, in accordance with the Rules, shall be his first consideration; next to which he shall use his best exertions to render the establishment effective as a school for the study of insanity, and the dissemination of knowledge respecting its nature, causes, and proper treatment. To effect which,—

"He shall admit as pupils medical students who comply with the rules prepared for such cases; the Governors reserving to themselves the right of nominating, from the Metropolitan Hospitals, ten pupils, who shall attend gratuitously.

"He shall make such regulations for their instruction, consistent with the comfort of the patients, and the educational proceedings in the other hospitals, as he may see fit.

"The pupils shall have the privilege of attending all *post-mortem* examinations made in the Hospital.

"He shall give, during each term, a course of lectures, to be illustrated by the cases under consideration at the time.

"He shall, at the close of each term, examine the several pupils, and shall recommend to the Committee the most proficient of them for appointment as Clinical Clerk.

"His salary shall be 700*l.* per annum, exclusive of Pupil's Fees, with a residence in the Hospital, furnished with planned and fitted furniture, and an annual allowance of coals, not exceeding twenty tons, with a limited supply of gas."

We regret, however, most deeply, to find that the resident Physician is to be "under the control of the President! the Treasurer!! the Committee!!! and the Bethlem Sub-committee"!!!!

God help the unfortunate wight! We much doubt that any "Fellow or Licentiate of the College of Physicians in London, Edinburgh, or Dublin, or a Doctor of Medicine of the University of Oxford, Cambridge, or Edinburgh, qualified to practise as a Physician," worth such a salary as is offered, will be found to accept the office under the terms proposed. *Mais nous verrons.*

CANCER HOSPITAL.

On Friday last, Dr. Marsden became a petitioner at the Court of Common Council for a grant of a hundred guineas towards his Free Cancer Hospital. It was only the accident of but one alderman being present,—more being required for the proper constitution of the Court,—that prevented his application from being acceded to. After what we said in our last Number relative to the vice of special hospitals, it will be needless to state, that we rejoice at this defeat (temporary though it may be) of an attempt to drain the public purse on behalf of an object which we have shown to be opposed to the progress of medical science, and to the good of the public. Our thanks are due to Dr. Clark for his bold opposition; and, if Dr. Marsden should again have the temerity to demand public support for his scheme. We shall look to the able Common-Councilman to do battle on behalf of the Profession. Dr. Clark's remarks are the very echoes of our own words; indeed, from the highest authorities in the Profession to the lowest, we find we have given utterance to the general sentiment, and have received thanks on all hands for the stand we have determined to make against a nuisance which is becoming intolerable.

By an advertisement in the *Times* of Monday relative to the Free Cancer Hospital, we perceive that an appeal is being made to the public to provide a house, furniture, a matron,

beds, etc., to receive in-patients; and, towards this object, Mrs. Wolrige's fund, we are informed, has been set aside. How can Dr. Marsden have the conscience to squander money so unprofitably, seeing day by day, as he must do, the unoccupied condition of his own hospital—the Royal Free? Here he might find a ward to his hand, which we would engage could be furnished for less than the sum he has already received. We put it, then, to the members of the Common Council, whether he has a right to demand of them a hundred guineas for sheer waste? If the cure of a terrible disease is what he aims at, is there any reason why the empty wing of an old-established Hospital should not be as acceptable to him as a distinct building?

As Dr. Marsden is the chief promoter of the scheme, we presume this advertisement, with reference to the Free Cancer Hospital, received his sanction. Will he, therefore, have the kindness to explain the exact meaning of the following extract from it:—"This institution has now been in existence twelve months, during which period a larger number of patients suffering under this dreadful malady has been brought together, than at any other period, clearly showing the necessity (!) there is for an institution exclusively devoted to the treatment of this *hitherto*-considered incurable disease." Of course the meaning of the term "*hitherto*-considered incurable disease" can only be, that it is now curable. Indeed! We are deeply thankful to hear it. But who has found out the cure for this terrible scourge? Whose art has enabled us to turn aside the fatal shaft which, but too often, the poor patient is bound to witness quivering in his healthful-looking frame? Has Dr. Marsden had the glory of conferring this blessing upon poor suffering humanity? Is he in possession of the secret which will suddenly arrest the erring cell-growth which squanders human life? If so, we have done him grievous wrong; instead of grudging him a simple hospital, we should urge that public honours be decreed to him—that his name be enrolled in our glorious annals beside those of Harvey and Jenner. What, on the other hand, if it be not so; if the physician still finds with dismay the lurking death-spot—if the use of this phrase be only a trick, in short, to get subscriptions; why, then, we say, that those who drew it up wrote more in the spirit of members of the British College of Health than of the College of Physicians. They use language calculated to convey an untruth, and to impose upon the public.

Again, as though one wretched delusion were not enough in the space of a short advertisement, we find the following:—"Although many deaths have occurred out of the 194 cases which, up to the present time, have been under treatment, it is highly gratifying to report, that a large number have been greatly alleviated, *and several incipient cases discharged completely cured.*" Is there such a thing, good reader, as an incipient untruth? If so, we admit incipient cancer; but by no means its complete cure; and the staff of the Free Cancer Hospital must be daring indeed, if they pretend to have extinguished, in one single case, the cancer germs elaborated by the body. By means of the *Times*' advertising sheet, they may mount their rostrum in the market-place, and launch forth promises they can never redeem. They may impose upon an ignorant and confiding public; but the Profession cannot be so imposed upon.

Dr. Marsden and his *confrères* have no more power than other men to stop the development of this fatal disease; they have the power, however, if unchecked, of promoting a malignant growth, whose tendency, with others of a similar class, is to destroy the body medical.

Special hospitals, such as we have spoken of, are the true cancerous developments, springing up in pestilential crops in every part of the Metropolis, draining the life-blood out of the great establishments, and producing no healthy results of their own. The most objectionable of these is the "Free Cancer Hospital," now only an "incipient case;" and we shall do all that lies in our power to discharge it "completely cured."

INCOME-TAX.

For a year longer we must bear the unjust burden of the present Income-tax; and, in one form or another, an Income-tax will, without doubt, be imposed permanently on the community. The only question is, shall the permanent tax be as unequally levied as the temporary one has been? This question is one of deep interest to the miserably paid and hardly worked members of our Profession.

At the last annual meeting of the Provincial Medical and Surgical Association, a Committee was appointed to watch over the interests of the Profession involved in this matter. Some short time since that Committee issued an address "to the members of the Medical Profession." We are anxious that our readers, who are not members of the Association, should be apprised of the object of that address, and, as far as possible, that they should assist the Committee in their labours.

After recapitulating the oft-told injustice inflicted on the Practitioner of Medicine by the present Income-tax, the Address proceeds:—

"The Committee of the Association, therefore, deem it to be their duty to inform the Profession, that they are determined energetically to oppose the re-enactment of this impost. They suggest the propriety of immediately assembling the local committees, and call upon every medical man, whether he is a member of the Association or not, to co-operate with them in their exertions to accomplish the above object."

"The Committee will be happy to receive suggestions, emanating from any medical man, as to the best mode of proceeding in furtherance of their object. They will be thankful for the names of those who are willing to come forward and volunteer evidence before the Committee of the House of Commons. They will feel greatly obliged to any medical man, whose engagements will not permit him to take a more active part, to communicate his opinions to the Secretary of the Committee. And, lastly, should any individual desire that the *facts only* of his letter be made known, his communication will be regarded as confidential, and his name not allowed to transpire."

There cannot be a doubt, that, if we are to be fairly used in the new tax, our case must be urged on the attention of the Government, and that, for the accomplishment of that object, an organization of the Profession is essential. The Committee of the Provincial Association offers such an organisation; and we trust that the appeal of that Committee will be heartily responded to by the members of our Profession. All communications on the subject are to be addressed to the Honorary Secretary of the Committee, Dr. Thomas Smith, Portland House, Cheltenham.

THE SWINEY PROFESSORSHIP OF GEOLOGY.

The audacity and impudence of the mesmerists and homœopaths pass belief. With the most slender pretensions or qualifications, they rush into an arena within which ordinary men would fear to tread. Who otherwise would credit the fact, that Dr. Macdonald, of St. Andrews, known chiefly, if not wholly, to the scientific world as the supporter of the follies of Mesmer and the absurdities of Hahnemann, placed himself as a candidate for the Swiney Professorship of Geology in

opposition to Professor Grant, the first and oldest of the palæontologists of England! He has deservedly met the fate of all who arrogate to themselves qualifications they do not possess—disappointment, if not disgrace. The election took place on Saturday last. Dr. Grant was proposed by the President of the College of Physicians, seconded by Sir Philip Egerton, and unanimously elected by the Trustees of the British Museum, to whom the Professorship is entrusted. Dr. Macdonald will return to Scotland a sadder, if not a wiser man. We congratulate the scientific men of the Metropolis on this appointment. The high scientific character and eloquence of Dr. Grant are well known and highly appreciated by all who know them. Dr. Grant's income, the miserable pittance on which he has eked out existence, and at the same time sustained his independence by a wise economy, will be nearly doubled for the ensuing five years; but his friends must not, on that account, relax in their praiseworthy exertions to present him with the testimonial in the shape of a permanent addition to his income, or cease those claims on the Government for a share of the fund set apart for the reward of eminence in literature or science. We sincerely congratulate the worthy Professor on his new appointment, and we have a reasonable hope that the other efforts now making for him will be crowned with a success co-efficient to his most meritorious scientific labours.

REVIEWS.

Observations in Surgery. By Benjamin Travers, Jun., F.R.C.S. 8vo. Pp. 230. London: Longman and Co. 1852.

Much benefit would accrue to medical and surgical practice, if those only who have had an extended and ample experience, and have by this means been able to test the truth of those great doctrines which the master-spirits of the present and bygone age have promulgated, were to give to the Profession the results of their inquiry into particular measures instituted with the view of combating certain troublesome and ill-understood forms of disease. Our large hospitals may with truth be considered as the best and widest sphere for the medical or surgical philosopher to make inquiries which may lead to some safe and satisfactory conclusions. If, to large opportunities of seeing disease, a man carries with him a sound head, a reflecting and unprejudiced mind, he will gain such an amount of practical knowledge, that, by being well digested and well put together, may prove of great use to those inquirers who may not have been so fortunate in their opportunities. Mr. Benjamin Travers, from his position as Resident Assistant-Surgeon at St. Thomas's Hospital for some time, has had under his immediate observation a mass of material from which to extract facts which could be useful to the spread of surgical science. To what extent he has succeeded, those who study the work before us will be able to judge for themselves; they will find some observations on very important points of practical surgery.

The subjects upon which Mr. Travers has written are Fracture, Injuries of the Head and Brain, Diseases of the Urino-Genital Organs, Local Inflammation, and some Diseases of the Joints. On the subject of Fracture will be found some judicious and practical observations, and more especially in reference to the constitutional treatment of simple and compound fracture—an element which is, we fear, too often overlooked by the surgeon who has various cases of surgical disease under his care. Mr. Travers rightly estimates the extreme difficulty which obtains in arriving at a judicious and correct conclusion as to the question of amputation in certain compound injuries. He, perhaps, a little underrates the resources of Nature, which may be relied upon to a wonderful extent for the repair of injuries which at first sight appear to be truly formidable.

In the chapters on injury to the head and brain, some useful matter will be found; and the Author has given, at page 97, an admirable description of commencing inflammation of the brain after the reception of an injury, which, if we had space, we should quote entire. To these are added a number of instances of injury to the head, and death by commotion or shock.

The author devotes a considerable portion of the work to the consideration of diseases of the urino-genital organs. He is a strong advocate for puncturing the bladder by the rectum when that last measure is necessary. In the treatment of stricture, he objects to the use of bougies, always preferring the use of the silver instrument. Mr. Travers must either be uncommonly skilled in the use of the catheter, or can have had no good opportunity of seeing what an immense amount of mischief is daily caused by the indiscriminate use of solid instruments, for otherwise he would come to a different conclusion about their use and that of bougies. We feel certain that the metal instruments are used too frequently; that they produce vast mischief, sometimes destroying life, and at least complicating the case of stricture to a great degree; and that, in the majority of cases of severe stricture, wax bougies are the most proper and least likely to create mischief. The following are Mr. Travers's opinions about perineal section:—

"The question of cutting upon old and callous strictures has been largely discussed of late, and much that has been said might well have been spared, because the proposition is not novel in itself, and some of the moderns would extend their application of the rule to many of the cases which do not call for such summary measures. It may be roundly asserted, that so long as surfaces remain unbroken, cutting instruments should not be used in the perineal region."—P. 172.

Mr. Travers is correct in what he here states, and we confidently predict, that, in a few years, we shall hear no more of the shameful cutting operations for stricture which have of late been performed with loss of life and the greatest danger and distress to the patients; but that this measure will be confined to those instances where Le Dran and Hunter counselled and performed it, namely, when there is impassable stricture and extensive fistulæ, and change of texture in the perinæum. Here alone is it necessary; and the surgeon who performs it when he can pass a catheter, commits a cruel and unjustifiable act. It is useless to disguise the truth,—facts which have come to our knowledge compel us to speak in this way of the "perineal section," as lately adopted.

The author gives his views on lithotrity, but we do not suppose, from the paucity of cases he refers to, that he has had a sufficient amount of experience of that operation to be enabled to come to any correct conclusion about this difficult question. Still, he is certainly not far wrong in saying, that "it has not yet been proved that any better or safer plan of treatment can be adopted than that of cutting in perineo, as first performed by the great Cheselden, now more than one hundred years ago." Nevertheless, statistics of lithotrity which *may be depended on* are required, before surgeons can come to any definite conclusion as to which is the safest operation—lithotrity or lithotomy.

Some observations on local inflammation and disease of the joints finish the volume, which is creditable to the author, who has had large opportunities of seeing disease, and has evidently observed it pretty closely.

Varicose Veins and Varicose Ulcers. By T. W. Nunn. 8vo. Pp. 63. London: Henry Renshaw. 1852.

Mr. Nunn has done some service to himself, as well as for surgery, by publishing this little work, which is written in a modest and unpretending manner. He has handled the subject under consideration as a philosophical anatomist and surgeon should do; and in a small space has conveyed a great deal of information respecting the nature and treatment of varix. In the first section he has given the anatomy and physiology of the healthy subcutaneous veins. In the second part he describes the pathology of varicose veins, and their consequences; and, in the third and last chapter, the author dwells upon the treatment which has been adopted for their cure, and describes the method which he himself has put in force with most success.

The particular changes which take place in the structure and form of a vein, when become varicose, are clearly given; and, as an instance of Mr. Nunn's style and accuracy of description, we quote the following in reference to varicose ulcer:—

"The varicose ulcer is always found below the knee. It is

usually irregularly shaped, its edges are thickened, and not of a constant colour; the neighbouring tissues are indurated, leaden to the touch and eye. The granulations vary in appearance; sometimes of bright red, sometimes dull red, or dull red mixed with yellow; the condition of the ulcer in this respect depending on the intensity of the inflammatory process, and upon its complicity with other affections of the general system."—P. 39.

Mr. Nunn does not like the ordinary method of obliterating varicose veins by ligature. The objections to it we may mention in his own words:—

"Although the obliteration of a vein is very seldom followed by results of an untoward character, yet it cannot be looked upon as a sure, safe, and convenient operation, and one which in all cases can be justifiably adopted; and, secondly, often a short time after the operation, the varicosity which it is intended to do away with re-establishes itself to its former extent."—P. 45.

The author imitates, or attempts to imitate, the result which is brought about by the ligature by milder means. These are, the continued application of pressure to the vein.

"By the application of pads fitted with elastic bands, by which continuous compression may be maintained, all the advantages of what has been called the radical cure may be obtained, without any of the danger attendant on that proceeding."—P. 52.

This treatment is simple, and likely to be effectual, we should think, as it is founded upon rational and scientific principles; but Mr. Nunn has not told us to what extent he has been successful with it in his own practice, and thus his work is incomplete. Mr. Nunn has perhaps underrated the efficacy of the "strap and bandage" in varicose and other ulcers of the lower extremity, urging as arguments against this mode of treatment, that "the discharge is confined, and that, moreover, excessive suffering is often produced." Now, with reference to the first objection, it may be fairly questioned, when we bear in mind that it is in those instances of ulcers where there is not a tendency in the part to secrete much pus, the strap and bandage is so beneficial, and, moreover, the confinement of a moderate amount of discharge appears not only not to be injurious, but absolutely useful, to a prompter healing of the sore; and, as regards the "excessive suffering" which is produced, we think that if the strapping is properly applied, and in cases only which have lost the irritability and sensitiveness which obtains when they first come under the surgeon's care, but little if any pain will be experienced by the patient. In varicose ulcers especially is this treatment applicable.

We cordially recommend every practical surgeon to make himself acquainted with the contents of this little book, which, we again say, does the author much credit.

Medical Dictionary for the People. By Spencer Thomson, M.D., &c. Parts I.—IV. London: Groombridge.

Dr. Spencer Thomson is well known as a provincial physician of celebrity, and as the author of a very excellent Work on British Cholera, and of one not less excellent on Temperance and Total Abstinence. He has now commenced a Work intended not so much as a book on domestic medicine (although it includes this) as a general popular treatise on physiology, hygienics, and, in fact, everything which concerns the well-being of the community. Works of this class are of great utility. We are convinced that if the public knew more of the structure of their own bodies, and of the functions of the different organs, they would not only preserve better their own health, but they would understand and appreciate both the difficulties and the triumphs, the obstacles and the methods taken to overcome them, which render the practice of medicine the most onerous, as well as the most useful art which men can exercise. If people were more instructed, quacks would flourish less, and praise and blame would be more judiciously awarded to the practitioners of medicine than they now are. The works of Combe and of Lord are evidences of how much may be done to popularise physiology with advantage to every one, and we can pay no greater compliment to Dr. Spencer Thomson, than to say, that he seems to us to be a worthy follower of those two excellent writers, and to be doing for the practice of medicine what they did for physiology. The amount of useful information conveyed in this work is surprising, and here and there wood-cuts are put in, which nurses and persons about the sick, who cannot have the doctor always at hand, will find very valuable. Throughout, however, Dr. Thomson has shown very distinctly, that, although a little knowledge on the part of the patient may materially assist the physician, no amount of knowledge which a patient can acquire can supersede him; and there are many sensible remarks on self and quack-treatment.

GENERAL CORRESPONDENCE.

THE FRACTURE SWING.

[To the Editor of the Medical Times and Gazette.]

Sir,—I forward you the following remarks as explanatory of the mechanical means which have been adopted in the treatment of fractures, and should only feel hurt if I have assumed more to myself than was true; although, having been an observer of the various contrivances which have been suggested by different authors, I am as yet ignorant as to whether any other principles more applicable have been promoted by any of my Professional brethren.

Previously to the year 1831, the mechanical means for the treatment of fractures in use among English surgeons consisted of the straight split splint for the arm and thigh; with Sir Astley Cooper's double inclined plane for the thigh; the common leg-splint, with the outer footboard; and Sir James Earle's fracture-bed. It was in consequence of such inefficient methods, that led me then to contrive and publish what I believe, and the subsequent experience of twenty years has demonstrated, to be such as would more easily keep the fractured ends of bones in apposition, and with the least excoriating tendency of the soft parts. In reference to this latter principle, I suggested the mode of applying pressure or support as applied to tumours by Dr. Neile Arnott, namely, the compound act of a resistible against an irresistible support. The first suggestion, in reference to the apparatus for fractures then in use, was for femur; I saw the great imperfection of the double inclined plane, because, there being no security to the pelvic structure, hence rotation and shortening of the fractured limb. I therefore added a concave extremity, which allowed the the tuberosity of the ischium to rest on the bed with an impossibility of any lateral movement; and, further, to secure more fully the pelvic end of the os femoris, I added a pelvic strap. This addition effected the complete security of all kinds of fractures of the femur, and, in my opinion, superseding the straight splint by Desault. The adaptation of this principle to the thigh led me to apply the same to fractures of the humerus, by securing the lateral appliances to the scapula, making the acromion a fixed point, by means of a strap or belt passed over the upper part of the instrument, and carried round the chest, under the opposite axilla.(a) To this form of humeral splints has recently been added, by Messrs. Weiss and Co., a support for the forearm, having the advantages of a well-applied sling, and is now in general use.(b) In treatment of fractures of the radius, the hand was not sufficiently protected from the act of pronation. I had the inner splint so made as to keep the hand in a position of partial supination, as described in the twelfth volume of the *Medical Gazette*. The next defect I observed was, in the system of supports applied to fractures of the clavicle, mainly owing to carrying the arm in a sling from the neck, which led me to apply a strong leathern pad over the posterior part of the scapulæ, secured by a belt across the fore-part of the chest, to which was appended a loop on either side to suspend the hand, thereby throwing the arm backwards, and allowing the head and neck perfect freedom of movement, also enabling the patient to walk more erect; the scapulæ were fixed by two padded straps passed round the axilla and over the acromion process of the scapula. I now come to the treatment of fractures of the tibia and fibula by suspension,—a principle introduced into England by myself, in 1831. I find it is not fully understood by many, as to its great advantages. A Correspondent in the *Medical Times and Gazette*, Mr. Roberts, has just published a letter, advocating, as a new principle, the ball and socket joint to the suspension-frame of Mr. Luke. With all due respect to both these gentlemen, I do not think either have observed the simplicity of the original invention. In my work, "Facts and Observations in Medicine and Surgery," p. 31, is a letter from the late Dr. Wigan, author of the "Duality of the Mind;" I make no apology for republishing it, as it explains the subject of suspension in a practical manner:—

"It was about the year 1820, that Mr. George Young, the most successful of London surgeons, having made a fortune perfectly

(a) Vide *Medical Gazette*, Vol. XII.

(b) Since my publication of this splint, in the twelfth volume of the *Medical Gazette*, with the other forms of fracture apparatus for fractures, they have been much simplified, and the cost greatly reduced.

unprecedented by any man not attached to a hospital school,—returned from a tour in Germany. He had entirely relinquished his practice, but still took great interest in suggesting improvements to his professional friends, and, in the course of one of his friendly explanations, showed me an apparatus, which he had witnessed in Germany, for the management of fractures. It was a shelf, suspended by four cords from the corners; and he spoke in the highest terms of the advantages it possessed over the ordinary modes of management, that the limb being suspended, enabled the patient to get out of bed without disturbing it. It was in vain that I endeavoured to comprehend its advantages; and, being a tolerable mechanic, I could not help regarding it as a clumsy contrivance, and thought no more about it. My practice in London had a very small admixture of surgery, and the thing passed away from my memory.

"In the year 1826 or 27, I resided several months at Lausanne, where the apparatus was pointed out to me by Mr. Mayor, the surgeon to the hospital there, as the invention of a German, not, I believe, a medical man. I now saw that Mr. George Young had repeated the old story of the French cook,—he had made the plum-pudding quite correctly, but omitted the cloth,—he had shown the mode of suspending the broken limb, but had forgotten that four points of suspension allowed no motion, and entirely neutralized the principle; that it was only on tying all four together, at a convenient distance from the board, that you obtained the *universal joint* of mechanics—the ball and socket.

"The moment I saw this, I comprehended in an instant its numerous advantages, and found that it might be rendered useful in a great variety of cases, not merely fractures of the lower limbs, but of the arm and many other injuries; might be the means of preventing anchylosis, by removing the necessity of confinement to one position, etc.

"I saw it employed in many cases at Lausanne, and was the means of introducing it into some parts of Italy and France; but, although I had often seen patients get in and out of bed without any assistance, and without risk of disturbing the limb, and spared no asseverations to convince, it was rare that I could get any one to comprehend fully the extreme simplicity and perfection of the apparatus, and I was often unsuccessful. I have observed all over Europe, that surgeons are miserable mechanics, and have seen many apparatus by common bone-setters, Greeks, Germans, and Dutch, which would shame our hospital surgeons.

"On my return to England, I endeavoured in vain to get the plan adopted in various hospitals, but as I soon after left London, and removed to a country town, it is not surprising that I was even less successful there; for although it contained a hospital and a large population, it was not large enough to remove the jealousy which is the besetting sin of the Profession. I should believe that I myself partook of the feeling, if I did not know that '*oneself*' *is always exempt from prejudice*, and that it is only 'others' who are influenced by that odious defect.

"In passing from Lausanne into Italy, I found a lady (the Hon. Mrs. H.) at a miserable cottage in the high Alps, who had been six weeks on the floor, having broken her leg by the fall of the mule, in passing over the Wengern Alp. Serious injury was coming on in various parts of the body, from confinement to one position. On the application of the new apparatus, she was immediately able to rise; her gratitude was unbounded, and her recovery so rapid, that a few weeks afterwards I encountered her at Milan, quite restored.

"For many years I have given up surgery altogether, and do not know whether the plan I speak of is become more general—it well deserves to be so; but I believe it is the very simplicity of the contrivance which constitutes the obstacle to its adoption.

"Dr. Mayor never claimed the merit of the invention, but he made great efforts to teach the peasantry of the mountains the use of the apparatus, which was within the means of every one to construct—a matter of importance in their insulated life, where they could not procure surgical aid at any price, (even if they could afford it,) for five or six months together.

"The mode of fastening which I saw in Switzerland was rather clumsy and complicated. I substituted the *guy*, which I think is an improvement." I am, &c.

JOHN GRANTHAM, F.R.C.S.

THE UTERINE SOUND.

[To the Editor of the Medical Times and Gazette.]

SIR,—I must once more, and for the last time, beg for a space in your columns, in reply to "M.D. Londin.," an indulgence I would not have asked for had not this Correspondent endeavoured, in his last communication, to fix on me three sufficiently unpleasant faults: 1st, of malpractice; 2ndly, of loss of temper; and, 3rdly, of a desire to shirk fair discussion. Before, however, I proceed to notice this attack, I will briefly recapitulate the facts and circumstances of our controversy, in order that the Profession may see the tone and manner in which "M.D." exercises his self-imposed duties of anonymous critic, and the advantages it is likely to obtain by his ascertaining for it whether "published statements bear the interpretation put upon them."

Some time during October and December of last year, Dr. Rigby, a gentleman as much esteemed for his private worth as he is respected for his professional attainments, published in your journal sundry cases of obstructed dysmenorrhœa, which he had diagnosed by means of the uterine sound, and treated instrumentally, etc. On the 21st February of the present year, "M.D. Londin." thought proper to comment on these cases, at the same time impugning the morality, decency, and propriety of Dr. Rigby's proceedings.

Now, that there may be no mistake on this point, I will quote from "M.D.'s" own paper. He says: "Sir,—In the leading article of your Journal for February 7, you justly reprobate the very improper use of the speculum, in the treatment of uterine diseases, adopted by some physicians. . . . But, while you lend your powerful support to the suppression of such abominations, alike uncalled for by the nature of the disease, and demoralizing to the female subjected to them without just cause, you admit a series of articles, on 'Dysmenorrhœa,' signed by the time-honoured name (in midwifery) of 'Edward Rigby, M.D.,' which are scarcely less mischievous in their tendency than the statements and practices so justly condemned." Again, in the third paragraph, after commenting on Dr. Rigby's mode of treating this class of cases, we have: "Hence, a young virgin female, who suffers from pain 'only a few hours' before the appearance of the catamenia, is to have her person exposed, her delicacy violated, her uterus forcibly dilated by 'blades made of well-tempered steel,' or slit open with a knife ingeniously contrived for the purpose. Was there ever a more monstrous proposition put forth in sober earnestness?" Not contented with this, "M.D." next attempts to fasten on Dr. Rigby a charge of ignorance or of falsehood, inasmuch as Dr. Rigby had stated, that, in the case of Miss B., aged 36, where he found a diminished os and cervix uteri, he had passed the uterine sound to a distance of "rather more than two and a-half inches," subsequently "dilating the os slightly, when some brownish bloody-coloured fluid came away," with ultimate relief to the malady. "But," says "M.D." "the new point worthy of note is, 'the uterine sound passed more than two and a half inches.' To have passed so far, it must have penetrated the os uteri internum; and, as it is surmounted by a bulb, which measures from a quarter to half an inch in diameter, this bulb must have passed through the orifices of the uterus. Now, in the healthy condition, these orifices are not so large as to admit an instrument of this size to pass, and hence, according to Dr. Rigby's report, those parts were morbidly enlarged, not contracted. The escape of 'some brownish, bloody-coloured fluid' would, as already stated, follow the introduction of the sound, and no facts are given to show that it was catamenial fluid." Twice professing to quote the words of Dr. Rigby between inverted commas, "M.D." omits the word *rather*—"the uterine sound *passed more than* 2½ inches." For what purpose is this inaccuracy—this omission?

All this, with true self-respect, Dr. Rigby has treated with the silent contempt which it deserves; but, I ask, is it right that he, or any other professional man, wishing to record the experiences of his observation, should be subjected to such attacks from one who has not the courage to fight in his own name, under the plea, "that published statements should be freely examined, and that this can be done as well under one name as under another;" that is, as well by one who, using an assumed name, incurs no responsibility, nor gives any voucher for accuracy or truth, as by him who honestly affixes his signature and awaits boldly the consequences of his conduct.

Being at this time engaged on a paper in defence of a much-abused and misunderstood instrument, and believing, as I still do, that "M.D. Londin.," was either disparaging an instrument of which he was entirely ignorant, or knowingly mis-stating its size for some unfair purpose towards both Dr. Rigby and the instrument, I asked, in a note appended to my paper on the Uterine Sound, when and where he, "M.D.," had seen such an instrument, etc. (See *Medical Times and Gazette* for February 28.) Three or four weeks afterwards, "M. D. Londin.," endeavours to shuffle out of the manifest blunder he had committed, by saying, that I had corrected him of a "serious typographical error," (see his letter of March 27th.) "The bulb of the uterine sound is stated," says he, "to be half an inch in diameter; it ought to be half an inch in circumference." Now, in this apparently candid confession of error, "M.D." was guilty, as I pointed out on the 17th of April,"

of a direct *suggestio falsi*, through the common medium of a *suppressio veri*. His original measurement of the sound was from a "quarter to half an inch in diameter;" but, when commented upon for this, he deliberately omits all reference to the quarter inch diameter, and endeavours to draw away attention from his exaggeration by stating, that instead of half an inch in diameter, he meant to say half an inch in circumference. It is also rather remarkable, that though he has impeached the veracity of the "time-honoured" Rigby, on the express consideration that Dr. Rigby had professed to have used an instrument too large for the natural calibre of the parts, &c., he has not once volunteered a regret towards Dr. Rigby for a typographical error, as he calls it, fraught with such serious consequences, but has been solely occupied ever since in an ingenious, but too transparent, attempt to wriggle himself out of the difficulty, by drawing attention to his largest measurement only—"I should have said half an inch in circumference, not diameter," thus trying to accommodate his next trial at a description to a plain *ex post facto* examination of the uterine sound, as well as to the accurate measurement of it which I had given. And, let me observe further, that he has not yet, in spite of his show of candour, attempted any explanation of what he meant to convey by saying, that the bulb varied from "a quarter to half an inch in diameter," though I have, in a former letter, challenged him to do so.

"There are no tricks in plain and simple faith."

As to "M.D." 's criticisms on certain cases of mine, and the various charges he has founded on them against me, I am quite indifferent. I have received too many letters on the subject of my paper, both from London and elsewhere, to permit me to feel any anxiety on that score; but I must allude to one specimen of his criticism, which occurs in his last letter, where he attempts to show that my treatment of obstructed dysmenorrhœa was as "uncalled for, and consequently as improper," as Dr. Rigby's, (see p. 449,) wherein he complains of my professing to have discovered stricture of the os internum uteri by the sound; and insinuates, what I have nowhere stated, that I had in this case passed the instrument through the uterine canal, which I did not do; for, surely, as with the male urethra, a stricture, or contracted condition of this canal may be ascertained, without penetrating the constriction, by the obstruction which the instrument receives at the narrowed part. This he ought to know; but, alas! it is too clear that his criticisms are altogether of the "*sic volo, sic jubeo*" kind. If the escape of a "brownish, bloody-coloured fluid" from a dilated os and cervix uteri be not an indication of a canal, (whether quite pervious or not,) preternaturally and relatively too small for its purposes, I ask what it is an indication of? If this discharge be not evidence of retained menstrual fluid, what is it? I unhesitatingly repeat, that the proper dimensions of the uterine sound, as given in my paper, are not too large for a normal uterine canal; and that the uterine canal, just as the male urethra, need not be entirely closed to produce a serious functional derangement of the catamenial secretion.

I suspect "M.D. Londin." has long been

"Letting down buckets into empty wells,
And growing old in drawing nothing up."

As to my loss of temper, I confess I am not myself conscious of it. It is an old saying, that none are so apt to accuse others of being drunk as those who are themselves intoxicated; at any rate, none more commonly believe others angry than those who are so themselves. No, Sir, I am not angry, but sorry—sorry that, in a Profession so calculated to engender all that is honourable, and accurate, and generous, there are to be found persons, some even grey-haired, who are not only capable of, but absolutely take pleasure in, loose statements, exaggerated descriptions, and vilifying comments,—in fact, in "construing things after their fashion, clean from the purpose of the things themselves,"—that these ungenerous attacks should be directed, not only against the humbler members of the Profession like myself, but reach even the "great ones of the city," the Rigbys, Simpsons, etc., etc.

I have no desire to avoid honest and fair criticism of any and every act and production of mine; but I will not subscribe to the doctrine, that it is either necessary, convenient, or proper, that an anonymous writer should

"have a liberty
Withal, as large a charter as the wind,
To blow on whom he pleases."

But I am also accused by "M.D." of a convenient shirking of discussion on the subjects of our communications. Now, on this point I beg distinctly to state, that if "M.D. Londin." be not afraid or ashamed to write in his own name, I will pledge myself, on the honour of a gentleman, to discuss these matters with him dispassionately, and without any more reference to diameters or circumferences, commencing, if he pleases, with the differential diagnosis of pendulous tumours of the uterus and pregnancy in the ninth month. If he decline my challenge, he must pardon me if I resolve not to notice anything further from his pen unless authenticated by his proper signature, however unfounded, uncandid, or ridiculous it may be. I am, &c.

Birkenhead, Cheshire. CHARLES HAYES HIGGINS.

BETHLEM HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—Some insinuations having been thrown out in the public papers as to the causes which have induced the Governors of Bethlem Hospital to propose some additions to their medical staff, may I request that you will do me the favour to insert in your journal the following letters referring to the subject.

These I conceive will at once vindicate the present medical officers from every shadow of supposed imputation as to the performance of their official duties.

These changes purely result from long-standing intentions on the part of the Governors, and (as will appear from their own letter) have no connexion whatever with any report received from the Commissioners in Lunacy.—I am, Sir, &c.

EDWARD THOMAS MONRO, M.D.

87, Harley-street, Cavendish-square.

TO THE PRESIDENT, TREASURER, AND COMMITTEE OF THE ROYAL HOSPITALS OF BRIDEWELL AND BETHLEM.

MY LORDS AND GENTLEMEN,—We have heard that a special meeting of the Committee is to be held at Bridewell, on Monday next, to consider and report what should be the duties, salary, and emoluments of the Resident Physician of Bethlem Hospital, *and upon no other business*; and it is further rumoured, that a special general court is to meet on the following Monday, to confirm the resolutions of the Committee.

As no other business than that above referred to is to be considered, we have no other means of obtaining a hearing than by addressing the individual members of the Committee; and the urgency with which important changes in the medical staff of the hospital are to be carried out, without our being informed of any ground of complaint against the present officers, seems to justify this course.

If the changes which the Governors have resolved to make have been determined on in consequence of a report which has been made to the Secretary of State by the Commissioners in Lunacy, we most respectfully claim the right to be informed what the report is, and the evidence upon which it is founded.

We feel that we can confidently challenge comparison between the condition of Bethlem Hospital and that of any similar Institution; and those Governors who have attended the Sub-committee and visited the wards have uniformly expressed their opinion of its good order, and the satisfactory state of the patients generally, in a book under their own hands.

The cures during the last seven years have not only equalled, but exceeded, those of any corresponding period since the hospital was founded. Mechanical restraint has been gradually diminished, and at last altogether discontinued. Upon these grounds, we earnestly appeal to the Committee, whether changes which must necessarily degrade us all, and in our persons dishonour our profession, should be thus hastily made, without giving us the opportunity of defending ourselves against any charges which may have been made against us.

We have the honour to be,
My Lords and Gentlemen,
Your faithful servants,
ED. THOS. MONRO, M.D.
ALEX. MORISON, M.D.
WM. WOOD, M.D.

Bethlem Hospital, 30th April, 1852.

Bridewell Hospital, May 7, 1852.

Gentlemen,—I beg to inform you that your letters of the 27th and 30th of April last, and the 3rd of May instant, with an enclosure addressed to the President, Treasurer, and Committee of Bethlem Hospital, were laid before them, and read at their meeting this day, and I am directed to acquaint you, in reply, that the Committee are very desirous of removing, as far as lies in their power, any impression on your minds, that the proceedings which they have taken with reference to the appointment of a resident Physician, are the result of the acquiescence on their part with the Reports of the Commissioners in Lunacy to the Secretary of State for the Home Department.

The appointment of a Resident Physician and Medical Superintendent, which was unanimously agreed to by the Committee and unanimously confirmed by the last Court, had long been felt by the President and Treasurer, and many Governors who have devoted much attention to the administration of Bethlem Hospital, and who possess considerable experience in the direction of similar establishments, to be a necessary and desirable alteration in the system pursued at Bethlem Hospital, where, in consequence of the number of patients having doubled since the appointment of the present Physicians, the introduction of employments on an extended scale, the classification of the patients under the charge of numerous subordinate officers, and the increased duties involved in the improved and daily improving treatment of lunatics, a degree of constant supervision at all times, direct control and undivided responsibility, was imperatively demanded, which it was not in the power of any non-resident physicians under the present system to secure.

It is both the duty and the desire of the Governors to afford any officer who may feel himself aggrieved, the fullest opportunity of explanation and defence; and, had the Report and evidence complained by the physicians been a document under the control of the Committee, they would most readily furnish them with copies; but the physicians are aware, that the investigation originated with the Commissioners in Lunacy, and that, by the express and positive direction of the present Secretary of State, the evidence must be confined in the strictest confidence to the members of the Committee. As the Secretary of State is alone empowered to furnish the physicians with copies of the Reports and evidence, the Committee can only refer them to that authority for compliance with their request; should they, however, wish to submit any statement on the subject, the Committee will receive it, and give it their best consideration.

The physicians will thus understand, that the Committee have not entered upon the consideration of that Report, and that, therefore, no opinion has been expressed by them on the several conclusions at which the Commissioners in Lunacy may have arrived; and although it is true, that the present medical staff is stated to be insufficient in resident officers for the due management of the hospital, that is a defect in the system, as before stated, which they have long intended to remedy when an opportunity occurred.

I am, Gentlemen, your obedient Servant,

B. WELTON, Clerk.

To Dr. Monro and Sir Alexander Morison,
Physicians to Bethlem Hospital.

DR. BACHOFFNER'S NEW FIRE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the last Monthly Number of the *Medical Times and Gazette*, I perceive, at page 355, a notice of "Dr. Bachoffner's Fire without Coal." By the name, I presume Dr. Bachoffner is a German. However much I may admire his ingenious experiments, I cannot, in justice to myself, allow the opportunity to pass without informing you, that a British medical man established that principle upwards of twenty years ago, when he was a medical student in Edinburgh University, the particulars of which will be found in the *Edinburgh Philosophical Journal* of the time. I beg to enclose a notice from the *Scotsman* that was taken of my experiments, which, if you would place in juxta-position to those of Dr Bachoffner, will explain the whole matter.

I should feel much obliged if you would transfer this notice to the pages of the *Medical Times and Gazette*.

"Let the reader imagine a tin lamp of the ordinary form, the cavity of which is filled with strong spirits instead of oil. A cotton wick lies among the spirits. One end of it is brought through the orifice or mouth of the lamp in the usual way, and the different threads of which it consists are separated, and spread out a little, so as to leave a sort of cavity in the middle. Into this cavity is placed a coil of platina wire, of a cone shape, formed by five or six spiral turns of wire. The wire is about the hundredth part of an inch in diameter, and the coil forms a sort of cup, about $\frac{3}{8}$ths of an inch wide, in the middle of which lies a small piece of spongy platina. The lamp being filled with spirits, the wick is to be inflamed: in about a minute the platina becomes red hot; the flame is then blown out, and the glass cover placed over the lamp. The use of this cover is to confine the heat, and prevent all cross currents, so that no air may reach the platina, except what passes in by air-holes below, and escapes by the chimney or opening in the cover above. If the lamp is standing in a chamber somewhat darkened, the platina will now be seen constantly presenting that glowing or incandescent appearance which we observe in red-hot iron. The light is strong enough to enable one to see the hour on the dial-plate of a watch at midnight, but produces no annoying glare. The spirits are decomposed and fly off, forming, as Mr. Merryweather thinks, water and acetic acid.

"Such is the lamp in its simplest state, that is, when consisting merely of one burner. If a greater heat is wanted, three, six, or more burners may be placed upon one lamp. In the lamp exhibited to the Royal Society, Mr. Merryweather employed fifteen burners, placed near one another; and with these he maintained a perfectly constant temperature of 396° Fahr. We call it a lamp, but when fitted on this scale, a furnace is the more appropriate appellation. He was informed that this was a very desirable heat for many chemical or pharmaceutical purposes; but he could, if necessary, raise it to 1000°. He found that the platina wires and sponge undergo no sensible waste, and observes that, by connecting a reservoir of spirits with the cavity of the lamp, the heat might be kept at the same uniform elevation for years. Pure alcohol is not necessary. He finds that whiskey 22 per cent. over proof, 9s. per gallon, answers perfectly well. With fifteen burners, producing a temperature of 396°, the quantity of spirits consumed in twelve hours costs 1s. 3d.; with three burners, yielding a heat of 160°, the cost is 3d., which is not great, if compared with the expense of attendance when the same object is obtained by means of common fuel. It may be proper to mention, that the glass cover placed over the lamp with fifteen burners, was a cylinder about seven or eight inches wide, and ten or twelve inches high; and the heat alluded to was kept up within a space of this extent, which was empty, and of course available for experiments."

I am, &c. GEO. MERRYWEATHER, M.D.

Whitby.

THE CAUSES OF CALCULI.

[To the Editor of the Medical Times and Gazette.]

SIR,—The letter in your Number of last week, from Mr. Henderson, of Curzon-street, and enclosure from Dr. Leydig, of Mainz, opens an interesting and important question, which I hope will not cease to be mooted, until some more exact information than has yet been placed before the Profession is elicited. So general an announcement as is contained in those two epistles is startling, considering the nature of the complaint it refers to. I speak from reminiscences, but my impression is strong, that by far the majority of cases of calculus happen either in very young subjects, or in persons somewhat advanced in life. The varying nature of calculi further point to some causes susceptible of greater variety than the mere habit of drinking certain wines, which at least, it is to be supposed, the infants in whom this complaint appears do not. My own observations lead me to believe, that neither the kind of water nor the wine drank habitually have much to do with the matter, that is, so far as they aid or impede the functions of digestion, and influence the transpiration and secretion from the kidneys. I have every reason, as I will presently show, to believe that a wine may produce calculus; but I very much doubt any such liquid having a general preventive power independent of the habits and constitution of the individual; and if I might hazard a conjecture, to induce others to publish the results of their own experience, I would suggest, that a moist and changeable atmosphere, with sudden exposure to cold, may form a principal cause of this disease in infants, owing to a peculiar diathesis, and that habits such as are known to produce gout, as inactivity, repletion, and astringents, are most frequently the origin of this disease in more advanced life. There are still many circumstances, which, as accidental causes, operate in numerous instances; and we all well know, that a very slight exudation or extravasation in any of the urinary passages, will prove a nucleus, when the secretion is either overcharged with any of its peculiar saline ingredients, or impeded, so as to permit their abnormal deposition internally. Of all bodily sufferings, I think it is the most serious and excruciating. I speak from personal experience. If you consider my own case of sufficient interest to afford any clue to the solution of the general question, you can make what use you like of it. Although it tends to the supposition, that certain wines, or wine in a certain condition, may produce calculus, I do not know that it bears more upon the subject than illustrating how accurately the cause and progress of such a case may be followed, when all the circumstances connected with it are taken into consideration. In the year 1837, I was engaged in some experiments on the production of wine from unripened grapes and other materials. I then made an effervescing wine, which was bottled, and opened at somewhat too early a period. A friend who was with me examining this wine, approved it, and I took some glasses of it, having dined. I was soon after seized with what I considered at the time a violent attack of rachialgic colic, which I attributed to something I had eaten, hardly suspecting this new wine had much influence in the matter. The attack disap-

peared under simple measures. A year or so after I felt some pain in the region of the left kidney, which gradually took the course of the ureter, clearly indicating the cause. This became intolerable at the valvular entrance of the ureter, until the passage through the valve was effected. Then commenced the usual symptoms of vesical calculus. First occasional, next frequent sudden stoppages of the urine, which nevertheless found a passage as through a severe stricture. I at length determined, instead of continuing my efforts to empty the bladder upon the next occasion when the calculus should become impacted, to cease all endeavours, and allow it, by position and relaxation of the muscles, to enter the canal. I have no doubt it will be considered a hazardous experiment. It succeeded, however, completely, for, upon the bladder becoming well filled, my efforts at once expelled the stone. From its colour and roughness I concluded it to be of the mulberry species; but, upon present inspection—for it is before me—I consider it an unusually rough specimen of lithic acid. While upon the subject, I may refer to a case I once had, leading me to believe some instances of calculus may, as formerly asserted, have been cured by the process afterwards recommended, and at one time freely resorted to for relieving irritable bladder, viz., injection of warm water by the double catheter. When practising abroad, a woman presented herself for advice, complaining of constant pain in the perinæum and surrounding parts. The surgeon of the 17th Regiment was dining with me, and I went from table to see the patient. I felt convinced from the first, that the cause was a vesical calculus; but, having a friend so near, and thinking it a case which would require some manipulating aid, and that my friend would feel interest in assisting me therein, I requested him to see the woman also. He differed with me, and pronounced an opinion, that the mischief was rather referable to some disease of the rectum, which should first become the matter for consideration. We freely expressed our views. A few days afterwards the patient returned to me in great agony, with a calculus, about the size of a horse-bean, just presenting from the urethra. This was easily removed with a pair of dressing forceps; and, a sound being introduced, another of considerable size was discovered. Shortly after, by dilating the urethra, this was broken and extracted piecemeal with a pair of bullet-forceps. Some of the fragments, being covered with mucus and tinged with blood, were put into a glass of warm water to cleanse them for preservation. I soon perceived they were falling away, and dissolving in it like lumps of sugar. I therefore collected all I could, and have still nearly all that remained undissolved. I submit we may hence hope, that, at least in some cases, when the indurated exterior of some of the calculi composed of the lithates is penetrated by crushing, the more difficult process of extraction may be facilitated by solution,—if, indeed, we may not expect, by persevering endeavours, to give relief more frequently by diluted injections of chemical solvents. I am, &c.

12, Finchley-road. HENRY JEANNERET.

MEDICAL NOMENCLATURE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Every suggestion or fact regarding variola and vaccinia is of some importance at present, when their prophylaxis is so prominent a subject of study. Concurring with Dr. Gregory on one important point,—that it is quite essential that the process of vaccination should be a legislative injunction,—I at the same time differ with him entirely on his general deductions. It is probable, indeed, that, had not Dr. Jenner so confidently offered his aphoristic pledge, Dr. Gregory's paper would not have been written, inasmuch as it is mainly based on general disappointment—the frequent failure of vaccine prophylaxis. But this is not quite the fair mode of argument. We should form our judgment, not on the failure of the full premises, but on the amount of blessing which vaccination has really conferred on mankind, quite independently of Dr. Jenner's premature confidence. But the real number of these failures is immensely below what the public is unwisely led to believe; and the avoidable causes of the great majority may be at once satisfactorily explained. The Epidemiological Committee has been for some time engaged in the framing of its Report, and in this statement I would beg to suggest to it the adoption of terms and definitions which may be more appropriate and intelligible than those now employed. The word "inoculation," for instance, should be discarded, and "variolation," in contrast with "vaccination," adopted in its stead. The term, "varioloid," is altogether a mistake; modified variola *is* variola in a slighter and less malignant form; therefore its diminutive, "variella," is the proper word. There is at this moment an extensively-prevailing error on this point. The Report of a learned society may at once insure the adoption of these and many other terms to which I might allude. I am, &c. WALTER C. DENDY.

St. James's-park.

INGROWING TOE-NAILS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I wish you and your surgical correspondents would devote some little time and space to the consideration of the best curative means in the case of ingrowing toe-nails. "Who shall decide when doctors disagree?" I find Mr. Erasmus Wilson, a first-rate authority in diseases of the skin, objecting (in his treatise) to the scraping of the surface of the nail; while Mr. J. F. South, in his allusion to the subject, recommends the scraping of the nail to the thinness of a sheet of writing paper, in order to restore its elasticity; while he objects, at the same time, to the plugging of the nail with lint or cotton-wool; whereas almost all chiropodists invariably adopt that method of preventing the nail from imbedding itself in the flesh. Some surgeons use the lancet freely; others refuse to cut, except when ulceration has actually commenced. Some, again, will take off half the nail, while others content themselves with the removal of a lateral section, etc. I have a sad case in point, of nearly two years' standing. The patient, a young man in excellent health, and about thirty-two years of age, suffers from a tendency of the great toe-nail, on each foot, to grow too convexly, and so to penetrate the flesh on the external side. In the more aggravated case (that of the right foot), the proximate cause of the evil appears to have been the pressure of a tight (or short) shoe, which thrust the fleshy part of the toe upwards, and over the side of the nail, so that the latter, instead of growing on the surface of the skin, as in the normal state, became imbedded (convexly) in a cavity of the flesh, and, after the lapse of a few months, provoked inflammation and ulceration. In April, 1851, (nine months after the first slight inconvenience had been experienced), a small section was taken (with the lancet) from the side of the nail, but hardly sufficient to relieve nature; added to which circumstance, a splinter was left, which gradually grew forwards, and in the ensuing month of August transfixed the fleshy cavity, and produced an ulcer of the most exquisitely painful kind. Poultices and caustic having been applied in vain, a larger section was taken off by means of the lancet; the sore, which had been open and suppurating for nearly ten days, healed up immediately, and the patient enjoyed a respite of ease for about three months. In Dec., 1851, however, the side of the nail had grown up so far as to oppose a somewhat sharp angle to the flesh in which it was still partially imbedded, and slight inflammation supervened. In this state of things the patient applied to another surgeon, (of general skill and experience), and this gentleman determined to treat the case as follows:—Having cut away a sufficient portion of the nail—enough, *i. e.*, to relieve the soreness of the part—he scraped its ingrowing convex side to the greatest possible thinness, and as the new nail (or, rather, the new section of the nail) grew up, he continued to scrape it daily, from the matrix upwards, plugging the free edge and the adjoining angle with a pledget of lint; the object being to make the new nail sufficiently elastic to shoot over the fleshy cavity above-mentioned. The toe was also washed, twice a-day at least, with a strong solution of alum, for the purpose of corrugating the epidermous tissue, and enabling it to resist the pressure of the nail. The operation with the lancet and scissors took place in December last; the nail has now grown up to the critical point; the angle again tends to transfix the flesh, and occasions, at times, some slight soreness; but it is hoped and expected, (the nail being daily scraped at the side and near the matrix,) that the cure will be completed, and further operation with the lancet be avoided. Should the hope of the surgeon be disappointed, he proposes to take off half the nail, as the only radical remedy. I will take care to apprise you of the final result, and meanwhile shall be glad if some of your correspondents will communicate their ideas on the subject. This disease of ingrowing nails is a fearful one, and more common than many suppose; while neglect on the part of the patient too often necessitates a cruel and torturing operation. I am, &c.

Homerton, near Hackney. PHILO-CHIRURGUS.

IMPORTANT COUNTY COURT DECISION IN FAVOUR OF THE MEDICAL PROFESSION.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following is the report of a case lately tried in a County-court in this neighbourhood, and, as the decision given by His Honour the Judge is a rather important one to the members of

the Profession, who, like the plaintiff in this case, may, in order to establish their just rights and vindicate their characters, be compelled to sue parties in the local courts, you will, perhaps, do some good by inserting the particulars of this case, as the verdict given was a triumphant one, and does great credit and honour to the learned and worthy Judge. You would hardly believe it, Mr. Editor, that a Fellow of the Royal College of Surgeons, employed by the parties in question, came forward on the occasion of this trial, in favour of the defendants, for the purpose, if possible, of invalidating the very moderate charge made, by stating it to be too much! but the Judge would not hear him.

Bath. I am, &c. MEDICUS.

CASE.—On the 21st ult., a case which excited considerable interest was tried at the Chippenham County-court, before C. Smith, Esq., Judge. The action was brought by Dr. John Hanmer Sprague, as surgeon and general medical practitioner, against Isaac Ball, a policeman of the Great Western Railway Company. The plaintiff had attended Ball's wife and four children in malignant scarlet fever, the cases being some of the severest that occurred during the prevalence of the epidemic at Box in 1851; and, for attendance twice—and sometimes three times—a-day for a period of one month, a charge of one pound only was made, the medicines supplied being charged at one-half the usual surgeons' and apothecaries' prices! The bill amounted altogether to 4*l.* 19s. 6d., but this included a charge of 1*l.* for attendance, and dressing an extensive and severe wound of the thigh of a boy—the eldest son—who was run over by a cart, and for seeing him safely conveyed to the Bath Hospital, where he died in a few days after. This item appeared to be the principal bone of contention; but plaintiff, after giving more than twelve months' credit, had offered to take off ten shillings from his charge, provided the defendant agreed to pay, and, moreover, would have consented to receive it by small instalments. The defendant, however, instead of coming to any arrangement or settlement, had gone about making an entire misrepresentation with regard to plaintiff's charge, which he stated to be enormous! Plaintiff had been subjected to much abuse in consequence, and, in vindication of himself, he had found it requisite to bring the case before the Judge of the County-court. Several highly respectable medical practitioners testified to the "very reasonable and extremely moderate" nature of the charge made, as the attendance altogether extended over a period of three months; and, among the testimonials produced in court, were two from Messrs. Norman and Gore, surgeons to the Bath United Hospital. His Honour the Judge was pleased to state, that, during the whole of the time he had sat on the Judicial Bench, he had never seen a more moderate, reasonable, or just account, especially as it was proved, by the defendant's own admission, that he was in the receipt of a weekly income of twenty-five shillings, besides having all his clothing found him, and 5*l.* a-year paid by the Railway Company towards house-rent. Defendant also cultivated land, and kept pigs, etc., and therefore his income was more than equivalent to a medical man with 150*l.* a-year. His Honour remarked, that he only regretted that Dr. Sprague had not done justice to himself by charging much more; for, if he had charged double the amount, he should have felt it his duty to have awarded it, considering the nature of the services rendered; and there was no impeachment of skill, nor could the claim be justly disputed. His Honour, addressing defendant's attorney, said, he had been altogether misinstructed in the case, which he at once admitted. Dr. Sprague had done all in his power that a man could do to avoid bringing the defendant into court, and putting him to expense, which was much against his wish; but the fact was, His Honour said, it was evidently an attack upon character, in order to evade payment, and plaintiff had been compelled to seek redress. It was in self-justification that Dr. Sprague had brought this action; and, although he had generously offered to take off 10s. from his account, he should now allow him the original sum claimed. He only regretted it was not much more, for Dr. Sprague's sake. Medical men must be paid for their time and attendance on cases, as well as for the medicines supplied, which could not remunerate them; and he should always feel it to be his duty to support and uphold the welfare of the Profession.

A verdict was given in favour of the plaintiff, with costs, payable by monthly instalments of 1*l.*

LOOK AT HOME.

[To the Editor of the Medical Times and Gazette.]

SIR,—Nothing can be more useful than an examination of ourselves and our belongings.

In a church, the other day, I observed a stethoscope inside a hat, in so prominent a position that none could help seeing it. A physician, long since dead, spoke invariably of the stethoscope as "the trumpet;" and such, in the present instance, was, no doubt, the use intended to be made of it.

Now, Sir, could you not suggest to the merchant tailors, that they would confer a favour on the public by the invention of a convenient pocket, so as to remove the danger now incurred by heavy persons sitting on their stethoscopes, as this has been stated to be the reason why stethoscopes go to church in a hat.

I am, Sir, &c. X. Y. Z.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

J. HODGSON, Esq., F.R.S., President, in the Chair.

ON FIBRINOUS DEPOSITS ON THE LINING MEMBRANE OF VEINS.

BY HENRY LEE, Esq.

SIMPLE inflammation of the veins—that is to say, inflammation commencing in the coats of the veins—is regarded by the author as a very rare disease. The internal lining of veins especially would appear to be as little susceptible of inflammation as any structure in the body. The large number of instances of phlebitis met with in surgical works, and occurring in daily practice, are regarded by the author as depending upon, and as being excited by, a vitiated condition of the blood. This opinion is principally supported by the two following facts: first, that in every case of so-called inflammation of the veins, the blood will be found to have coagulated in the vessels; and, secondly, that where such coagulation does not take place, no inflammation will be produced. Continental writers of the highest reputation have, indeed, mentioned the concentric layers of lymph which are secreted as the result of inflammation in the interior of veins; and English writers, whose names carry with them the greatest authority, have described the adhesion of the opposed sides of veins by lymph secreted from the capillaries under a state of inflammation. The advocates of this view have particularly referred to an experiment by M. Gendrin, in which he mentions, that, by introducing irritating substances into the arteries and veins, he obtained large deposits of lymph upon their interior. The author, on the contrary, having found that inflammation of the coats of the veins only occurred in cases where the blood has previously coagulated in them, was induced to believe that the deposit found in the veins might be derived directly from the blood. M. Gendrin's experiment was therefore repeated, precautions being taken to exclude all blood from the vessel; and it was found that under these circumstances no lymph was effused in the vein. The lining membrane of the veins does not contain any blood-vessels of its own, nor does it require any, being in direct contact with the blood. It appears reasonable to suppose, that, under such circumstances, it would not secrete lymph, and the experiments and observation of the author lead him to this conclusion. The lining membrane of a vein, the outer coats of which are inflamed, may undergo various changes, or may be disintegrated, and cast off into the cavity of the vessel. Lymph and pus may then be secreted into the interior of the canal; but this can only occur in the latter stages of the disease. The readiness with which some morbid poisons produce coagulation of the blood, and the constancy with which such coagulation (indicated by the cord-like induration of the vessel) is found to precede the other symptoms of inflammation, lead to the conclusion, that a vitiated condition of the blood is the common cause of phlebitis. Under such circumstances, although the irritation produced is caused by the morbid matter detained in the vein, yet the inflammation is at first manifest in the surrounding parts. The cellular tissue becomes distended with serum; the cellular coat of the vein then becomes thickened, red, and inflamed; and, finally, the changes which have been noticed extend to the lining membrane. The effects of inflammation thus are shown to extend to, and not from, the internal surface of veins. M. Cruveilhier indeed regards the coagulation of blood in a vessel as the effect of inflammation previously existing. But the author has satisfied himself, that if blood be prevented from stagnating in a vein, no change will thereby be produced in its lining membrane. The inflammation is not, therefore, propagated by continuity of surface, as has been generally supposed, but by the stagnation, in different parts, of vitiated blood. Coagulation of the blood would therefore appear to be the cause, and not the effect, of inflammation of veins. This view is further supported by the fact, that simple adhesive in-

flammation of a vein will not produce coagulation of its contents. A preparation was exhibited, showing the effects of a ligature upon a vein twenty-four hours before death. No coagulation of the blood, nor deposit of fibrin on the lining membrane, had in this case taken place. The coats of the vein were thrown into folds, and a white band marked the situation of the ligature; but the projecting folds of the lining membrane presented their natural smooth, polished, and lubricated appearance. Healthy venous blood will remain fluid for days, when confined in a vein by a ligature. In this respect there is a contrast between a vein and an artery. In the latter case, the internal coats are divided, and the blood, coming in contact with the divided edges, immediately coagulates. In the vein, on the contrary, the lining membrane is not divided, and therefore the blood remains in contact only with the natural lining of the vessel. Cases in which a small quantity of pus has been introduced into a vein, afford the strongest contrast to those in which the coats have been mechanically irritated. In the latter case, no coagulum will form, or one only sufficient to unite any lesion there may be of the lining membrane. In the former, on the contrary, extensive fibrinous plugs will occupy the vessels. These will sometimes occupy the whole diameter of the vein, and become firmly attached to its sides; at other times, the outer layers only will become firmly coagulated, and the central ones will remain in a semi-fluid condition. It will sometimes happen, that the central portions will be removed, leaving the outer layers attached to the walls of the vessel. The circulation may then be continued through an adventitious cylinder of fibrin. Cases occasionally occur, in which a delicate velvety layer only is deposited on the lining membrane, which remains unaltered in appearance in other parts. The coagula which form in veins will, under such circumstances, lose, in different situations, much of their colouring matter; and it will be observed that the lining membrane of the vein is coloured (from imbibition) in exact proportion to the amount of colouring matter contained in the different parts of coagula. It will occasionally happen, that portions of the decolorized fibrin will become organized and intimately connected with the sides of the veins, as illustrated in a preparation exhibited to the Society. Such layers of fibrin appear constantly to have been mistaken for lymph, the product of inflammation. The extreme readiness with which the blood coagulates from the contact of purulent matter, affords a most important provision for the security of the general system. It appears to depend upon a faculty with which the blood is endowed for its self-preservation. This faculty, although hitherto unacknowledged by physiologists, doubtless exists, and is comparable to the preservative sensibility with which every other part of a living being is endowed. When purulent fluid is introduced into a vein, if the coagula are firmly formed, a local inflammation will alone ensue; but, if the morbid matter extends along the vessel, a high degree of constitutional irritation will follow, and the symptoms will occasionally bear a striking resemblance to those of typhus fever. In cases as they present themselves in practice, these two sets of symptoms are constantly present at the same time; but they may be produced separately by a very simple experiment: if, for instance, purulent fluid be introduced into a vein, and allowed to remain undisturbed, a local inflammation only will be set up, which will terminate in the formation of an abscess around the vein. The contents of the vein will then become softened, and expelled externally, together with the contents of the abscess. But, if the morbid matter be forced forward, in the course of the circulation, no local inflammation will occur, but the symptoms will indicate either the presence of secondary inflammation in some internal part, or of a general contamination of the blood. If the view taken of the origin of inflammation of the veins be correct, it will be evident, that any treatment, to be effectual, must have reference to the first periods of the disease; and that those remedies will most effectually guard the system against the contamination (so much dreaded in this class of cases) which will favour the sequestration of vitiated blood, and tend to localize the disease. The remedies which have been employed to subdue the local inflammation, appear but too often to have done so at the expense of the general system; for, although the local symptoms have become less prominent, fatal mischief has appeared in other parts. In severe cases, those remedies only can be safely employed which tend to preserve the power of the blood, and especially those which increase its coagulating power, so as to enable it to separate that portion which has become infected from the general circulation. Bark and opium, together with a nutritious diet, are the means which appear to favour these actions, upon the due performance of which the safety of the patient depends; while bleeding and calomel, however useful they may be in a case of simple inflammation of the coats of a vein, appear inadmissible when the disease, as generally happens, originates in its contents.

REMARKS ON HYDROPHOBIA.

By B. E. BRODHURST, Esq., M.R.C.S.

The author observed, that it was to *hydrophobia rabiosa*, or that disease which arose from inoculation with the saliva of a rabid animal, in contradistinction to *hydrophobia simplex*, that he was desirous of directing attention. Hydrophobia was a disease properly of the canine race, and did not arise spontaneously in man; but it was communicable to him from all rabid animals. There was no instance on record of the disease being communicated from man to man, although experiment proved that it could be transmitted from man to animals. There appeared to be a peculiar predisposition in the canine race to this disease. The author was inclined to believe that the disease occasionally arose spontaneously in the dog, although Mr. Youatt had expressed a contrary opinion, to the effect that it was propagated by inoculation alone. The author was led to the opinion opposed to that of Mr. Youatt, by observing that rabies was extremely rare in the south of Europe among the native dogs, but that it was by no means an unfrequent occurrence for an English dog to become rabid when taken to the south. The author considered that diet exercised a marked influence: that if a dog be allowed a diet principally of animal matter during the summer, he would almost certainly die hydrophobic. This applied equally to English and native dogs. Extreme cold and privation, however, also favoured the development of the disease, and seemed to be the most frequent cause of the malady among wolves. The author then proceeded to detail the more prominent symptoms produced on man by the bite of a rabid animal, as well as the periods within which they were usually developed. The wound healed without any peculiar indications, just as a similar bite by a healthy animal would heal; but at some uncertain period, often extending to forty or sixty days, pain was felt in the course of the nerves of the limb, and might be taken as the first positive indication of the approach of hydrophobia. Disturbance of the general health sometimes preceded this stage; the cicatrized wound became a sore. General nervous irritability and other manifestations of cerebral disorder, with mental emotions of fear and unnecessary dread on the approach of persons; hallucinations, spectral illusions, inordinate and disordered sensibility of the skin, with morbid increase of acuteness in the organs of special sense, were among the most characteristic signs of the confirmed disease. The author, who had witnessed three cases of hydrophobia, proceeded to relate the particulars of one which occurred in Vienna to a man 64 years of age, a farrier, who was bitten in the palm. The wound healed, and it was not till the forty-second day from the injury, after a debauch, that the patient awoke feverish, and with an aversion to water. He was removed to the hospital, under Professor Schulz. Various remedies were tried; cantharides, opium, belladonna. Tetanic spasms, of which opisthotonos was the expressive feature, came on. The convulsions continued, and, agitated with emotions of intense fear, he died. The body was examined by Rokitansky. The membranes, as well as the substance of the brain, were congested; the arachnoid opalescent; the bronchial and pulmonary mucous surfaces deeply congested; and the lungs remarkably engorged. The heart was empty, and the blood was fluid in the vessels; the mucous membrane of the kidneys and ureters congested. The bladder was pale, and all the other viscera healthy. The author stated, that the characteristic morbid appearance in the dog was an injected condition of the medulla oblongata and its membranes. But Rokitansky had stated, at the time of the above examination, that of the many cases he had examined, he had never found any appearances in the medulla oblongata which he could connect with the spasm. The author then directed attention to the certainty of the action of the saliva of a rabid animal when once introduced into the blood; not less certain, indeed, than that of a venomous serpent, though the period of its incubation was much longer. Although he admitted that one-third of those bitten might not manifest any symptoms, whereas the bite of a poisonous reptile was immediately followed by palpable effects, yet this immunity might be explained by the virus being wiped from the tooth before it penetrated, in the bite of a dog; while in a serpent the venom only exudes when the mandibular pressure ceases to be made. The author believed, that, as hydrophobia was primarily a blood disease, the presence of another blood disease, such as syphilis or variola, might arrest the hydrophobic poison. He regarded it as proved beyond doubt, that symptoms of hydrophobia had been arrested and suspended by variola; for hydrophobia could only develop itself after another poison, that might have been present at the period of inoculation, should have run its course. He rejected the doctrine, that the rabid poison could lie in a wound, and neither irritate nor be absorbed. It had been stated by writers, that the period of recrudescence was the commencement of the malady, the period of delitescence being overlooked. It was thus supposed, that the poison could lurk in

the wound, and that it was capable of being removed by excision at any time prior to the state of recrudescence. This disease, once developed, appeared necessarily fatal; treatment, therefore, to be effectual, should be vigorous and energetic in the primary or preventive period; and the author conceived, that as, in variola, its course might be retarded, and its intensity modified, by substituting another poison which had a certain affinity for the blood, so might it be hoped, that the hydrophobic poison might be rendered amenable to medical aid through the agency of mineral or animal matter. He mentioned the powerful effects on the blood of arsenic and mercury, and thought that one or other of these remedies, administered *ab initio*, might be productive of happy results. The author referred to the successful cases recorded by Wendt in the Breslau Hospital, where salivation appeared to have been practised with success, and where means were also used to remove the virus locally from the wound. The author, in conclusion, considered that the patient should remain under active treatment, in every case, from forty to sixty days; the influence of the mineral should be rapidly obtained and continued, so that a positive change might be effected in the blood, and the condition which favoured the hydrophobic virus destroyed.

Dr. Webster agreed with the author respecting the greater frequency of hydrophobia in cold than in warm climates. It is much more prevalent in the north of Europe than in Italy or France. In northern Germany, especially in Prussia, as he (Dr. Webster) could assert from his own knowledge, it produced marked ravages, which medical men ascribed to famished wolves from the forests of Poland during severe winters, infecting the village dogs, by whom the malady was afterwards spread. Mr. Brodhurst had alluded to an outbreak of this terrible scourge in Stockholm last winter; and he would add, that, about the beginning of this year, it prevailed like an epidemic in Altona and Hambnrgh, and also in several places in Holstein, and many persons died; cows and horses, especially the latter, were often attacked. Although less common in warm regions, it prevailed at times in them; while he was travelling in Italy some years ago, several fatal cases occurred, one being that of a priest, who had been bitten by a goat. Hydrophobia was very common last February in the lower Loire, among dogs, cats, and cows. This very day the newspapers reported the case of a physician practising at Valence, on the Rhone, who died from hydrophobia early in this month.(a) Contrasted with these statements, indicating considerable prevalence of canine madness on the Continent, it is very satisfactory to find that the disease is now much more rare in London than it used to be, only two fatal cases having occurred since 1846 in the metropolis, whereas sixteen deaths were recorded during the seven previous years. This remarkable immunity, he said, may be attributed to Mr. Fox Maule's Act, interdicting dogs being employed in drawing carts, whereby hydrophobia was said to have been often produced in these animals. Mr. Brodhurst's notion, that the blood became vitiated by the absorption of hydrophobic virus was not altogether new, but his recommendation of mercury, in order to counteract its deleterious influence, appeared more so. For instance, a Polish physician —Dr. Czajewski—read an interesting paper before the medical section of the scientific Congress of France, assembled at Orleans last autumn, in which he advocated somewhat similar views; but the treatment he recommended was very different. He advised copious bleedings every four or five days, until deliquium followed, so that before any serious symptoms supervened, the morbific taint being eliminated from the system, recovery might be more confidently anticipated. Notwithstanding various specifics for this disease have been occasionally brought forward, not one of them has ever stood the test of experience. Dr. Webster said, in conclusion, that having seen three fatal cases of hydrophobia, and believing that every kind of treatment hitherto employed has proved utterly inefficacious, he was inclined to think that the author's proposal of administering mercury in order to neutralise the poison deserved consideration.

Mr. M. Henry inquired the experience of the members of the Society as to the time when the disease developed itself after the reception of the poison? Some of the published cases appeared to be almost incredible.

Dr. James Bird had seen only two cases of the disease, both of them in Bombay. One was a sepoy, a stout, muscular man; the other an English officer. The first was attacked twelve months, the other six weeks, after having been bitten. In the case of the sepoy, the bitten part appeared to be affected with neuritis. There was a little tubercle at the cicatrix, which, when touched, threw the patient into convulsions. Mercury, given to ptyalism, appeared to relieve the violence of the symptoms, but it was used together with enemata of tobacco, so that it was difficult to determine which of the remedies caused the relief of the spasms. He died at the end of six or seven days. The officer died on the third or fourth day.

Dr. Th. Thompson alluded to a case in the practice of the late Mr. Hunter, of Islington,—that of a servant-girl, bitten by a rabid animal. The symptoms of hydrophobia showed themselves a week afterwards. An effect similar to that observed in the sepoy's case was produced by touching the cicatrix, the girl being immediately convulsed. An incision through the skin was made round the cicatrix, and then pressure ceased to cause spasm. The case ended fatally. He thought that this case, and that of Dr. Bird's, were somewhat against the theory, that the disease is dependent upon a morbid condition of the blood. Mr. Youatt placed much reliance on the administration of a mixture of belladonna with scutularis, as a preventive of the disease in dogs, after they had been bitten by a rabid animal. He made an extensive series of experiments with the medicine, and the result convinced him that it had some prophylactic power. With respect to the theory of the disease being dependent upon an altered condition of the blood, he might mention a certain train of symptoms, caused by the bite of a cat not in a rabid state. These consisted in wasting of the muscles, contraction, spasm, and neuralgia. There was sufficient analogy in these two conditions to show an argument against the blood theory.

The President had seen the case of a poor man, some years since, affected with hydrophobia, to whom belladonna was given to a great extent without any benefit. There were one or two points in the paper deserving notice. 1st. Was the disease as invariably fatal in the dog as in man? He had, some years since, made inquiries upon this point among persons likely to be well informed on the matter, and all agreed, that when attacked with hydrophia dogs invariably died. They all died within a fortnight after the accession of the symptoms. This was an important circumstance, because it was considered, that if a person were bitten by a dog supposed to be rabid, the fact that the dog survived the fortnight was regarded as an evidence of the safety of the bitten person. There was another practical point in the paper to which he would allude. He had seen a case some years since, which seemed to show that excision of the bitten part, at any time previous to the accession of the disease, would prevent its occurrence. A rabid dog bit two children, and their father afterwards in the arm. One child was bitten in the leg, the other in the shoulder; all slightly. The child that was bitten second was seized with hydrophobia. After this the father and the other child had the parts excised, and they escaped. This fact was important so far as it went; it would be observed, that the second person bitten died, so that the dog must have been mad when it bit the third. All the inquiries he had made in reference to the effect of incision of the bitten parts, tended to show that it insured the safety of the injured person.

Dr. T. Thompson wished to explain, that in Mr. Youatt's case the belladonna had been given as a prophylactic, and not as a curative remedy. Excision had been practised on two persons bitten at the same as the servant-girl at Islington, and successfully. The servant refused to submit to the slight operation, and died from the disease.

(a) The following is the case alluded to by Dr. Webster:—"Death from Hydrophobia.—Dr. Vanel, a young physician at Livron, remarkable for his talents and amiable disposition, died on the 8th inst. of hydrophobia. Somewhat more than a month back, a young puppy, which he was bringing up, bit him in the thumb of the left hand. As the mother of this dog had died mad, M. Vanel immediately applied caustic to the wound. The same puppy afterwards bit some other persons, and soon after died. M. Vanel then applied a red-hot iron to his wound, and no ill effects occurred. All his friends felt assured that nothing was to be apprehended, but the doctor himself grew melancholy, and always maintained that hydrophobia would certainly supervene. On the night of the 9th inst. his prediction was verified, as he was seized with violent agitation and fever, accompanied from time to time with convulsive symptoms. M. Mondan, the communal teacher, sat up with him the next night, and every attention was paid him, at first by Drs. Salette and Accarte, and afterwards by them conjointly with MM. Lherminier, senior and junior, physicians. 'My limbs,' said the patient, 'are all one mass of agony, but my mind remains intact. Do not fear me,' he added to those around him, 'I will not bite any one, for I have never been of a cruel disposition.' Every effort which he made to drink produced convulsions, and, after great suffering, he at last expired, retaining his intelligence to the last. He leaves behind him a young wife, about to give birth to a child, and a mother and sister, by whom he was much beloved. His loss will be deeply felt by the poor around.

STATISTICAL SOCIETY OF LONDON.

Lieut.-Col. W. H. Sykes, Vice-President, in the Chair.

MORTALITY AMONG MEDICAL MEN.

The first paper read to the meeting was one by Mr. Neison, the actuary to the Medical Invalid Life Office, on the rate of mortality among two different classes of medical men,—one class being the officers of the medical department of the Royal army, and the other class the members of the Royal Medical and Chirurgical Society. The facts relating to the former, Class I., had been taken from the records of the Society for the benefit of the widows of the

officers of the medical department of the Royal army, established in 1816; while the facts relating to the latter, Class II., were abstracted from the books of the Royal Medical and Chirurgical Society, instituted in the year 1805. Mr. Neison exhibited to the members of the Society a number of elaborate tables of the rate of mortality among the two classes of medical men referred to, as compared with that for Class III., the officers of the Bengal army, and Class IV., the male population of England and Wales generally. After stating that the various facts had been analysed with the utmost care, Mr. Neison commenced with explanatory observations upon the tables, and pointed out the influence of matrimony upon the duration of life in Class I., or the medical officers of the Royal army. It appeared that those of all ages of Class I. and earlier, who entered the Society unmarried, had been subjected to 14·665 years' risk, and the actual number of deaths had been 386, or 2·632 per cent.; while the rate of mortality for the like ages in Class IV., or the male population of England and Wales generally, was only 1·888 per cent. The irregularity in the mortality at particular ages was exceedingly curious; but it is impossible, in a short notice like the present, to give more than a general idea of the final results. The mortality in Class I. for the younger ages, 20 to 34, was shown to be exceedingly high; while, for the advanced ages, 55 to 84, it was found to be remarkably low. It appeared from another table, that those of all ages, of Class I., who entered the Society in the married state, had been subjected to 4·284,—five years' risk,—and there had been 120 deaths, giving a mortality per cent. of 2·801. Irregularities at particular ages were found to prevail among this class of members also, but not to so great an extent as among the unmarried members. The rate of mortality among all members of Class I., or those who entered the Society, whether married or unmarried, from its establishment to the 1st of January, 1851, for all ages from 25 to 84, was found to be 2·537 per cent.; while that for Class IV. was only 1·918 per cent. Other tables went minutely into detail as to the existing mortality of the single and married members of Class I. An after part of Mr. Neison's paper treats of the mortality of Class II., the members of the Royal Medical and Chirurgical Society, and also gives a chirurgical view of the Society from its commencement. A very complete table gave the rate of mortality among the members of the above Society for each quinquennial period of life from 26 to 70, and brought into comparison the similar results for Class IV. For the total ages, 26 to 70, there had been 7·834 years' risk, and 96 deaths, giving a mortality per cent. of 1·225; while the rate of mortality in Class IV. for the same ages was 1·239 per cent.; and the number of deaths that would have happened, according to this rate, would have been 97; from which it appears, that the rates of mortality in Class II. and IV. were almost identical.

At the conclusion of the paper, a discussion arose as to the causes of the irregularities mentioned in the mortality of Class I.

The paper is an exceedingly interesting one, worked up with great care and labour, and will appear in due time in the journal of the Statistical Society.

Colonel Sykes then read a paper on the

SICKNESS AND MORTALITY OF THE TROOPS (EUROPEAN AND NATIVE), UNDER THE GOVERNMENT OF BOMBAY,

for the year 1848 and 1849, during which the average of deaths to strength was, European 2·263 per cent., and native 0·933. This return, with the exception of that for the year 1832, is the most satisfactory upon record of the health of the Bombay Army, European and native, particularly in relation to the European portion of it. At some of the stations the mortality was less than it usually is within the United Kingdom. The heavy mortality of 5¼ per cent. among the European troops at Bombay, Colonel Sykes thought, might be partly owing to defective barrack ventilation, and to the nature of the soil upon which the barracks are built, but chiefly to intemperance. The mean annual deaths of the Europeans of the Bombay Army for 20 years, 1825 to 1844, was only 5·078 per cent., inclusive of losses from cholera, or ½ per cent. less than the loss in Bombay in the years 1848-9. Colonel Sykes concluded his valuable paper, which will be published in the journal of the Society, by drawing the attention of Insurance Companies in England to the fact of the native troops losing less than 1 in 100 per annum, and to the probable pecuniary advantages which would result from the establishment of insurance offices in India for the insurance of native lives, particularly the native public servants. Colonel Sykes finally exhibited to the meeting a very able historical and statistical chart of the progress of British commerce, from the Norman Conquest to the present time, by Mr. Bashly Britten; comprising also, for later times, public expenditure, prices of corn, rates of wages, etc. etc.

PARIS ACADEMY OF SCIENCES.

ON THE INFLUENCE OF THE GRAND SYMPATHETIC NERVOUS SYSTEM ON ANIMAL HEAT.

By M. CLAUDE BERNARD.

Researches have been for a long time conducted by different experimentalists, with the object of ascertaining the influence which the nervous system exercises on the temperature of the bodies of warm-blooded animals. From these researches we learn, that lesions of the nervous organs, cerebro-vertebral, constantly produce either a total or partial diminution of temperature according to whether we divide only the nerves which pass through a limited portion of the body, or operate upon the nervous centres themselves. M. Bernard has proved, from the researches which form the subject of his present communication, that, in acting on the ganglionary nervous system of the grand sympathetic, an inverse phenomenon is produced; that is to say, a very rapid elevation of temperature, capable of being readily ascertained. As yet, he has only been enabled to determine this elevation of temperature in a partial degree,—that is, in one member of a body, such as the face, etc. The following is one of his experiments relative to the head:—

When, in a mammiferous animal,—as, for instance, a dog, a horse, a cat, or a rabbit,—we cut the nervous filament in the middle of the neck, which serves as a communication between the inferior cervical ganglion and the superior cervical ganglion, or remove the cervical ganglion itself, an increase of heat through the whole corresponding side of the head of the animal takes place. This elevation of temperature occurs instantaneously, and developes itself so quickly, that in a few minutes, under certain circumstances, a difference of temperature, sometimes as much as three or four degrees, is found between one side of the head and the other. This difference in heat is readily ascertained by the hand, but is more conveniently determined by introducing comparative thermometers into the nostrils or ears of the animals. This difference of three or four degrees of temperature between the two sides of the face is remarkable; but if we then compare the heat of the ear and the nostril (thus increases by the section of the nerve) with the heat of the rectum or central parts of the body, the thorax or the abdomen, it is found to be nearly the same. M. Bernard has, however, sometimes found that the section of the filament of the cervical sympathetic nerve in the rabbit, produces an increase of heat in the corresponding ear to 40° centigrade, while the normal temperature in the rectum in that animal does not generally exceed 38° or 39°.

M. Bernard announced that this communication is but the prelude of a series of investigations to which he proposes to call the attention of the Academy. At present, he confines himself to noticing the above experiment, which proves that a very different influence is exercised on animal heat when the nerves of the grand sympathetic are acted upon instead of the nerves of the spinal marrow.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 6, 1852:—

Blomfield, Andrew Muskett, Barton. Norfolk.
Crosby, Thomas Boor, Gasberton, Lincolnshire.
Gabriel, Alfred Edmund, Collumpton, Devon.
Hernage, Henry James, Nottingham.
Johnson, William Alfred, Warwickshire.
Kirby, Christopher, Halifax, York.
Masfen, William Edward, Stafford.
Ogden, Robert Thomas, Rochdale, Lancashire.
Saville, William, Wakefield, York.
Taunton, George, Oxford.

Obituary.—On the 26th of April, at Liverpool, John Hughes, Esq., surgeon, aged 44. On the same day, at Maddox-street, Bond-street, John Geo. Porter, jun., Esq, surgeon, late of Peterborough. On the 4th of January, at Paramatta, New South Wales, Bute Stuart, M.D., youngest son of the late James Stuart, Esq., Blairhall, M.B. On November 25, of consumption, at sea, James E. Partington, Esq., surgeon of the Lord Stanley, merchantman. On the 1st inst., — Day, Esq., surgeon, of Harlow, Essex. He was found lying lifeless in his garden. On the 26th ult., in Maddox-street, Matthew Scott Moore, M.D., formerly Superintending Surgeon of the Madras establishment. On the 6th instant, at his residence, Claremont-house, Cheltenham, Thomas R. Exham, M.D., aged 32. On the 5th instant, at his father's house, Brentwood, in

the 33rd year of his age, Thomas Shuttleworth Butler, Esq., M.R.C.S., Assistant-Surgeon in the H.E.I.C.S., Bombay.

Medical Appointments and Vacancies.—An assistant medical officer is wanted for the Lincolnshire Lunatic Asylum. Salary 50*l.* a-year, with residence, board, washing, etc., in the asylum. Candidates must possess the double qualification. Date of election May 20th. Mr. Hartwell has been elected surgeon to the Exeter Dispensary, his three opponents having retired; Mr. Amory, the retiring surgeon, has also been elected consulting surgeon to the Dispensary.

Military Appointments.—6th regiment of Foot, Assistant-surgeon Egerton James Pratt, from the 62d Foot, to be surgeon, vice John Murtagh, M.D., who retires upon half-pay. 10th Foot, acting-assistant-surgeon, Duncan Robertson Rennie, to be assistant-surgeon, vice Inglis, promoted in the 64th Foot. 62d Foot, Cornelius Clark Rutherford, gent., to be assistant-surgeon, vice Pratt, promoted in the 6th Foot. Hospital Staff acting assistant-surgeon, James Joseph Roosemalecocy, to be assistant-surgeon to the Forces, vice Jamesou, appointed to the 87th Foot.

Naval Appointments.—Surgeon John P. Burke, M.D. (1845), Assistant-surgeon William E. Hambly (1847), to the Buzzard.

Militia Appointments.—Commission signed by the Lord-Lieutenant of the County of Middlesex, Royal East Middlesex regiment of Militia, Francis Dalton, gent., to be surgeon. Commission signed by the Lord-Lieutenant of the County of Lancaster, Lanarkshire Regiment of Yeomanry Cavalry: Robert Logan, to be surgeon.

King's College Medical School. — The following was omitted in our last:—Scholars of 1852.—Senior scholar (3rd year), Macnamara, F. N.; 2nd year's scholar, Dowson, Edward; junior scholars (1st year), Buzzard, Thomas; Macnamara, C. N.; Bird, F.

St. George's Hospital School of Anatomy and Medicine. —In the award of prizes at this Institution, Mr. A. T. H. Waters received the *prize* in Clinical Medicine, and not the certificate, as erroneously stated in our last. The same gentleman also received Dr. Sibson's clinical prize.

Hospital for Sick Children, Great Ormond Street. —Her Majesty has graciously consented to become the patroness of this Institution, and has presented to its funds a donation of 100 guineas.

Infirmary for Asthma and Consumption.—The anniversary dinner was held on the 7th inst., the Earl of Shaftesbury presiding. It was stated, that upwards of 39,000 persons had been relieved since the establishment of the Infirmary in 1814, and that several wards had been opened recently. The out-patients during the past year amounted to 1700; the income being 775*l.* 19s. 9d., of which a balance of only 8*l.* 17s. was left.

Brompton Hospital for Consumption and Diseases of the Chest.—A festival in commemoration of the commencement of the east wing of this hospital was held lately at the Albion Tavern, His Royal Highness the Duke of Cambridge presiding. The Report stated, that the number of in-door patients was 474, of whom 316 had been discharged cured or greatly benefited, 68 died, and 90 were still under treatment. The number of out-patients during the year was 3199, being an increase of 136. The proposed new wing, it was stated, would give accommodation for 230 patients, and there are already 133 applicants for admission. The subscriptions during the evening amounted to 3318*l.*

Charity for Hospital Purposes.—Mr. Vyner has presented 50*l.* to the Free Cancer Hospital; the list of donations just published by the Committee amounts to upwards of 130*l.* The late Lord Panmure has bequeathed 1000*l.* to the Dundee Royal Infirmary, 300*l.* to the Dundee Lunatic Asylum, 500*l.* to the Montrose Natural History and Antiquarian Society, 1000*l.* to the Arbroath Infirmary, and 100*l.* to the Arbroath Destitute Sick Society. We are glad to record a new list of donations for the hospital for Sick Children, amounting to upwards of 300*l.* Among the donors we find the names of Lord Alvanley (21*l.*), Mrs. Best (10*l.*), Mr. Brett (31*l.* 10s.), Lord Calthorpe (10*l.*), Duke of Cleveland (20*l.*), Mr. Greene (21*l.*), Mr. Holford (50*l.*), Mr. Mills (21*l.*), Admiral Percy (31*l.* 10s.), Mr. Sheridan, M.P., (31*l.* 10s.), and Mr. Young (10*l.* 10s.) At the anniversary dinner for the Brompton Hospital for Diseases of the Chest, upwards of 3300*l.* were subscribed in its behalf. The Treasurer of the Royal Orthopædic Hospital, in Bloomsbury Square, has just received 500*l.*, being a bequest to the funds of the Institution, made by the late Mr. Mackenzie. He has also bequeathed 500*l.* to the Middlesex Hospital; 500*l.* to the Charing Cross Hospital; 300*l.* to the Marylebone General Dispensary, Welbeck-street; and 300*l.* to the Marylebone Provident Dispensary, Charlotte-street, Portland-place.

Medical Benevolent College.—The munificent gift of 100*l.* has just been presented to the Medical Benevolent College by Dr. Leslie, as one of the executors under the will of the late Mrs. Dunlop. Dr. Leslie has acted nobly in thus recognising the claims of this excellent Institution.

London Hospital Medical School.—The annual distribution of prizes took place on Tuesday, May 11th; William Cotton, Esq, D.C.L., Vice-President of the hospital, in the chair. The hospital gold medals awarded by the governors for zeal and intelligence in attendance on the patients in the wards. Medical.—Frederick Hall, Lincoln. Surgical.—Alfred Adams Mantell, Bitton. Medicine, senior class.—Gold medal, F. Hall; honorary certificate, Harry May, The Potteries, junior class.—Silver medal, Robert Walker Jenkins, London; honorary certificate, Joseph Porter, Rotherhithe. Surgery, senior class.—Gold medal, R. W. Jenkins; honorary certificate, F. Hall. Junior class.—Silver medal, Samuel Pratt Woodfall, Footscray. Anatomy and Physiology, senior class.—Gold medal, Horace Kersey Debenham; honorary certificate, John Charles Robertson, Purbrook. Junior class.—Silver medal, James Edger Edmunds, Burnham. Midwifery.—Gold medal, Robert Brudenell Carter, Leytonstone; honorary certificate, J. C. Robertson. Chemistry.—Silver medal, Alfred Phipos, Dalston; honorary certificate, Alexander Robert Kilroy, Plymouth. Materia Medica.—Silver medal, R. W. Jenkins; honorary certificate, H. K. Debenham. Forensic Medicine.—Silver medal, R. W. Jenkins; honorary certificate, William Henry Carter, Billericay. Botany.—Silver medal, R. W. Jenkins; honorary certificate, H. K. Debenham.

Queen's Hospital, Birmingham.—At the weekly Board of Queen's Hospital, held on Friday last, the Rev. Prebendary Gray in the chair; present, J. E. Piercy, Esq., Messrs. D. Barnett, G. Taylor, E. T. Cox, J. Griffin, M. Banks, J. Suckling, J. Watson, and T. Boucher,—the election of Dr. Heslop as Physician was ordered to be entered on the Minutes. The Vice-Principal instructed the Dean of the Faculty to forward the Report of Dr. Heslop's appointment to the Committee of Council of the Queen's Hospital; the appointment to be submitted to the Board of Governors of that Charity for confirmation at their next annual meeting.

University of St. Andrew's.—List of gentlemen who had the degree of Doctor of Medicine conferred upon them, May 7, 1852: — Francis Ayrton, M.R.C.S., and L.A.C., Liverpool; William Burns Beatson, M.R.C.S., and L.A.C., Peckham, Surrey, H.E.I.C.S., Bengal; James Strange Biggs, M.R.C.S., and L.A.C., Devizes, Wilts.; Charles Blatherwick, M.R.C.S., Titchfield, Hampshire, E.; James Boyd, L.F.P. and S., Glasgow, Beith, Ayrshire; Richard Cross, M.R.C.S., and L.A.C., Scarborough; Robert Butterfield Cumming, M.R.C.S., London; James Drummond, M.R.C.S. Ed., Edinburgh; David Duncan, M.R.C.S. Ed., Glasgow; Edward O'Callaghan Foott, M.R.C.S., Cork, Ireland; Benjamin Godfrey, L.A.C., Romsey, Hampshire; Edmund Grosvenor Goulden, M.R.C.S., and L.A.C., Hazel-grove, Cheshire; John Graham, F.R.C.S., and L.A.C., Essex; Horace Edward Philogonius Johnson, L.A.C., London; William Locke, M.R.C.S., and L.A.C., Hoddesdon, Herts; Charles Martin, M.R.C.S. Ed., Leicester; Samuel Mault, M.R.C.S. Ed., Nagercoil, South Travancore, E. Indies; James M'Cann, M.R.C.S., and L.A.C., London; Richard Budd Painter, M.R.C.S., and L.A.C., London; George Newport Pickstock, M.R.C.S., Belize, Honduras, W. Indies; John James Ridge, M.R.C.S., and L.A.C., Gravesend, Kent; Francis Salter, M.R.C.S., and L.A.C., Hayes, Middlesex; Samuel Stacy Skipton, London; Thomas James Vallance, M.R.C.S., and L.A.C., Stratford-house, Essex; Watkin Saudom Whylock, M.R.C.S., Southwark; William White Williams, M.R.C.P. L., and M.R.C.S., Gloucester; John Wills, M.R.C.S., Wiltshire. Mr. Benjamin Thomas Moore passed the requisite examinations, but, in consequence of an informality in his certificates, his degree was temporarily deferred.

Dr. Thomas Leigh Blundell has removed from Finsbury-place South, to No. 29, New Broad-street, late Dr. Frampton's.

National Ingratitude.—It is well known to many of our readers, that for several years past Mr. George Alfred Walker, a member of the Profession, has exerted himself most manfully, and without any assistance whatever, in an endeavour to abolish the disgusting plan of inhuming the dead in the midst of the living. So strenuously has he worked, that at last the Government were induced to bring forward a Metropolitan Interment Act, and it would be supposed, naturally enough, that they, the Government authorities, would immediately avail themselves of the great and valuable experience of Mr. Walker to assist them in carrying out the object first propounded by this gentleman. Not so, for they immediately gave the good things to other gentlemen, as will be seen by a Parliamentary Return, printed last Monday, showing

that, under this Metropolitan Interment Act, Dr. Southwood Smith had been paid a salary of 1,200*l.* a-year; Mr. C. Macaulay, secretary, 500*l.*; Mr. H. R. Williams, treasurer, 600*l.* (since the 8th of August last the office has been vacant); and to Mr. H. C. Edwards, clerk, 150*l.* *Palmam qui meruit ferat* must cease to be a household sentence after this treatment of Mr. Walker.

By the news from the Cape we learn, that the body of Dr. Laing, Staff-Surgeon, drowned in the wreck of the Birkenhead, has been washed ashore, with forty-eight other bodies.

On the 7th inst., Petitions were presented to the House of Commons from the Graduates of the University of London, praying that they might send representatives to Parliament.

Gutta Percha in Diseases of the Skin.—Dr. Graves, of Dublin, has used, since last November, a saturated solution of gutta percha in chloroform, as a topical application in various diseases of the skin. The success of this novel remedy has been very remarkable. Dr. Graves has written a paper on the subject, which will appear in the next number of the *Dublin Quarterly Journal of Medical Science.*

Mortality Notabilia.—In the week that ended Saturday, May 8, the number of deaths registered in the metropolitan districts was 972. In the ten corresponding weeks of 1842-51 the average number of deaths was 898, which, if raised in proportion to increase of population, becomes 988. The rate of mortality now prevailing, therefore, differs little from the average amount. The gradual decline of mortality which at this season accompanies an increasing temperature is shown as follows:—In the third week of March the deaths rose to 1208; in the second week of April they fell to 1051; and in the first week of May, to 972. The mean weekly temperatures that marked these several periods were 40·5°, 42·0°, and 48·1°. Of the 972 persons enumerated in the present Return, 498 were males and 474 females; 451 died under 15 years of age, 339 at 15 years and under 60, and 176 at 60 years and upwards. As compared with the results of the previous week, there is a decrease, both in the deaths caused by epidemics taken altogether, and those by diseases of the respiratory organs, the former having declined from 232 to 193, the latter from 187 to 166. Small-pox, to judge from its weekly mortality, seems to prevail in London to about the same extent that it has now done for a lengthened period. In the first week of the present year the deaths registered from this disease were 33; last week they were 31; and in the 17 weeks that intervened, the lowest number was 22, and occurred in March, and the highest, which occurred in January, was 43. The total number of cases in which small-pox has been fatal during the 19 weeks is 591, and the average of a week is 31. In the first week of the year scarlatina was fatal in 41 cases, it declined to 18 in the second week of March, and last week the number was 37; typhus carried off 50 persons in the first week of the year, it declined to 32 in the third week of March, rose to 47 in the third week of April, and last week the number was 33.

TO CORRESPONDENTS.

We have to intimate that, in future, all Communications for this Journal must be authenticated; gentlemen, therefore, who address us must favour us with their names,—certainly not for publication, but that we may be satisfied of their good faith. Henceforth, then, it is to be understood, that, when a letter is unnoticed, it is because the writer's card did not accompany it.

Gentlemen desiring personally to communicate with the Editor, on the business of the Journal, will find him during the Summer Months, on Tuesdays, Wednesdays, and Thursdays, between the hours of 12 and 2, at the Office, 46, Princes-street, Soho.

It is again requested that communications shall not be otherwise addressed than

To the Editor,
"Medical Times and Gazette" Office,
46, Princes-street, Soho,
London.

Mr. Pascoe's Case.—Having intimated, that our correspondence on this subject was closed, we must decline inserting several letters we have again received. The matter has already been most thoroughly investigated, and is quite exhausted. Doubtless, Mr. Pascoe will receive the Royal pardon.

[To the Editor of the Medical Times and Gazette.]

Sir,—In reference to a case of Dislocation of the Sternal End of the Clavicle backwards, which I published in a recent Number of your Journal, I find in your last week's Number a letter from a "St. George's Student," in which he endeavours to explain the occurrence of dislocation in place of fracture, by bringing forward proofs of the extraordinary strength of the clavicle. Now, however strong *experiments* may prove that bone to be, *experience* teaches us, that, of all bones in the body, this is the one most frequently broken; we know, moreover, that this accident often arises from direct violence. Your Correspondent's explanation, therefore, does not tell us why, in this case, dislocation took place instead of fracture.

I am, &c.,

Middlesex Hospital. Septimus W. Sibley.

We have to acknowledge the receipt of several authenticated letters from Edinburgh on the "mattress affair." We are obliged by the communications, but, for obvious reasons, do not publish the names of the writers. Our Correspondents will observe, that we have not as yet availed ourselves of a tithe of their information.

E. A. W. wishes to know "who is the first person recorded to have made any effort to instruct the deaf and dumb."

Mr. Lowe's paper on the excision of the os calcis will shortly appear.

M.D., and an Admirer of Religious Freedom, must, in accordance with rule, favour us with his name. When authenticated we will publish his letter.

Dr. Esdoile will be written to.

Allopath will be considered.

Mr. Bransby Cooper's proofs were not returned in time for this week's publication. We are delighted to accommodate gentlemen who desire to receive proofs, for their personal correction, of communications; but they must return them to the Office not later than Wednesday morning, if intended for the week's publication.

In reply to several Correspondents, we have to state, that our articles "Look at Home," *will* be continued. The disgraceful and unnatural union between the surgeon and chemist,—where the former sees patients gratuitously in the back shop of the latter,—will meet our early consideration.

A Friend.—We will endeavour to comply with the request.

COMMUNICATIONS have been received from—

Dr. Turnbull, of Liverpool; Mr. Jeanneret, of the Finchley-road; Dr. Esdaile, of Perth; Dr. Higgins, of Birkenhead—On the Uterine Sound; Mr. Saunders, of H.M. 47th Regiment; Mr. John Beale, of the Harrow-road; Dr. Monro, of Bethlem Hospital, and Harley-street; An Indignant Extra-Licentiate—On the Injustice of the Money Payments under the Proposed New Charter of the College of Physicians; A Jealous Quadragenarian—On the Electoral Privileges (?) under the New Charter of the College of Physicians; Dr. Roe, of Plymouth—On Uterine Diseases and their Treatment; Dr. Wright, of the West Yorkshire Lunatic Asylum—On Cholera in Asylums; Mr. Williams, of Truro; Mr. Grainger, of Highgate—On the Claims of the Medical Benevolent College; Mr. Ludlow, of Paternoster-row—Hospital Report; Mr. Dendy, of St. James's-park; Mr. Sankey, of Beckley, Sussex; Mr. Hunter, of Moffat, Dumfries-shire—Statistics of the Recruiting Service; G. A. W.; Dr. Dundas, of Liverpool; Allopath; Mr. Sibley, of the Middlesex Hospital; A Friend; Mr. Pretty, of Mornington-road; Mr. Hutton, of the Newcastle Infirmary; Mr. Lowes, of Gosport; Mr. Bottomley, of Croydon; Mr. Brodhurst, of the Royal Orthopædic Hospital, and Brook-street; A Country Subscriber; X. Y. Z.; Mr. [illegible]; Mr. Gibb, of the Newcastle Infirmary.

Portraits from the "Medical Circular"

of Mr. PROPERT, Mr. MARTIN, of Reigate, Dr. ASHWELL, Dr. NEIL ARNOTT, and Dr. BAINBRIDGE, are now ready, framed and glazed, price 3s. 6d. each.—Office, 4, Adam-street, Adelphi. The "Medical Circular" is published every alternate Wednesday, price 3d.; stamped, 4d. No. 10 will appear on the 19th inst.

DR. NOAD'S CHEMISTRY.

Just Published, in 8vo, price 10s. 6d. cloth, a New Edition, enlarged,

Chemical Manipulation and Analysis,

Qualitative and Quantitative; with an Introduction on Nomenclature, Formulæ, and Equivalent Proportions. By HENRY M. NOAD, Ph. D., Lecturer on Chemistry at St. George's Hospital.

The additions to this Edition, including Analytical Tables, Index, and much other important Matter, will be sold separately, price 4s. 6d. cloth.

Robert Baldwin, Paternoster-row.

Just published, 8vo, cloth, 4s.,

Reform in Private Lunatic Asylums.

By HENRY MONRO, M.B. Oxon.

By the same Author,

REMARKS ON INSANITY. 8vo cloth, 6s.

AN ESSAY ON STAMMERING. 8vo, 2s. 6d.

London: John Churchill, Princes-street, Soho.

Now ready, 8vo, with 159 Wood-cuts, 10s. 6d.,

Lectures on Histology. Delivered at

the Royal College of Surgeons of England. By JOHN QUEKETT, Author of "A Practical Treatise on the Use of the Microscope."

In 2 vols. 8vo, in 1, with Fifty Plates, containing Portraits, Plants, Facsimiles and Views of the Fortress of Lahore, price £1 11s. 6d.,

THIRTY-FIVE YEARS in the EAST: Adventures, Discovery, Experiments, Historical Sketches relating to the Punjab and Cashmere, in connexion with Medicine, Botany, and Pharmacy; together with an original Materia Medica and a Medical Vocabulary in four European and five Eastern Languages. By JOHN MARTIN HONIGBERGER, late Physician to the Court of Lahore.

Catalogue of Foreign Medical Books Gratis, on application, or per post, 6d. London: H. Baillière, Publisher, 219, Regent-street, and 290, Broadway, New York (U. S.).

THE GREAT AMERICAN MEDICAL DICTIONARY.

New and Enlarged Edition, brought up to October, 1851.

Now ready,

Medical Lexicon; a Dictionary of

Medical Science; containing a Concise Explanation of the various Subjects and Terms of Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Obstetrics, Medical Jurisprudence, &c. With the French and other Synonymes. Notices of Climate and of Celebrated Mineral Waters; Formulæ for various Officinal, Empirical, and Dietetic Preparations, etc By ROBLEY DUNGLISON, M.D., Professor of Institutes of Medicine, etc., in Jefferson Medical College, Philadelphia, etc. Eighth Edition, revised and greatly enlarged. In one very thick 8vo vol., of 927 large double-columned pages, 24s. bound.

LECTURES ON MATERIA MEDICA AND THERAPEUTICS, delivered in the College of Physicians and Surgeons of the University of the State of New York. By JOHN R. BECK, M.D. 8vo. 21s. bound.

MEDICAL LEXICON OF MODERN TERMINOLOGY. By D. M. REESE. 18mo. 3s. 6d.

A PRACTICAL TREATISE ON THE DISEASES and INJURIES of the URINARY BLADDER, the PROSTATE GLAND, and the URETHRA. 8vo. Illustrations. 21s.

THE DISPENSATORY OF THE UNITED STATES. Ninth Edition. 1851. 8vo. 32s.

A SHORT GUIDE FOR THE RATIONAL TREATMENT of CHILDREN in HEALTH and DISEASE, by WATER. By C. C. SCHIEFERDECKER, M.D. Crown 8vo. 7s. 6d.

London: Delf and Trubner, Importers of American Books, 12, Paternoster-row; and all Booksellers.

Surgical Instruments, and every Im-

plement necessary for Surgeons and Druggists, can be had (warranted best quality and moderate prices), retail, as well as wholesale, from the Manufacturer, JAMES ARNOLD, 35, West Smithfield, St. Bartholomew's Hospital, London.

WORKS ON CHEMISTRY.

Practical Chemistry; including

Analysis. With numerous Illustrations on Wood. By JOHN E. BOWMAN, Professor of Practical Chemistry in King's College, London. Foolscap 8vo, cloth, 6s. 6d.

A MANUAL OF CHEMISTRY, WITH NUMEROUS Illustrations on Wood. By GEORGE FOWNES, F.R.S. Third Edition, foolscap 8vo, cloth, 12s. 6d.

CHEMISTRY, AS EXEMPLIFYING THE WISDOM and BENEFICENCE of GOD. By GEORGE FOWNES, F.R.S. Second Edition, foolscap 8vo, cloth, 4s. 6d.

CHEMISTRY OF THE FOUR SEASONS: SPRING, SUMMER, AUTUMN, WINTER. Illustrated with Engravings on Wood. By THOMAS GRIFFITHS. Post 8vo, cloth, 10s. 6d.

CHEMISTRY, METEOROLOGY, AND THE FUNCTIONS of DIGESTION, considered with Reference to NATURAL THEOLOGY. Being the Bridgewater Treatise. By WILLIAM PROUT, M.D., F.R.S. Third Edition, 8vo, cloth, 15s.

INSTRUCTION IN CHEMICAL ANALYSIS AS practised in the Laboratory of Giessen. By C. REMIGIUS FRESENIUS. Edited by LLOYD BULLOCK.

QUALITATIVE, Third Edition, 8vo, cloth, 9s.

A PRACTICAL HANDBOOK OF MEDICAL CHEMISTRY. With numerous Illustrations on Wood. By JOHN E. BOWMAN. Fcap. 8vo, cloth, 6s. 6d.

THE FIRST STEP IN CHEMISTRY. By ROBERT GALLOWAY, F.C.S. Post 8vo, cloth, 3s.

A MANUAL OF QUALITATIVE ANALYSIS. By ROBERT GALLOWAY, F.C.S. Post 8vo, cloth, 4s.

London: John Churchill, Princes-street, Soho,

β QUININE, OR SULPHATE OF QUINIDINE,

A New Alkaloid discovered in the

Cinchona Barks.—The attention of the Medical Profession is solicited to this new and important Alkaloid, as its medicinal effects are reported to be quite equal to the Sulphate of Quinine. It is more soluble in water, has the same crystalline appearance, and is much cheaper in price than sulphate of quinine.

May be obtained in any quantity of William Henry Cole and Co., Wholesale Chemists, 101, High Holborn, London.

Also, Quinoidine, Quinine, Cinchonine, Salicine, Tannin, Strychnia, Pure Creosote, Chloroform, Santonine, Ergotine, etc., etc.

Prices may be obtained on application.

Kousso (Brayera Anthelmintica.)—

THE NEW REMEDY FOR TAPE-WORM.—Mr. KEATING begs to inform the Profession that he has made arrangements for a regular supply of this valuable medicine. Having just received a fresh quantity of the new crop, direct from its place of growth, he is enabled to offer it at 2s. the ounce, which can be sent free to any part of the Kingdom, on receipt of 28 Postage-stamps.

MATICO.

Mr. KEATING continues to receive importations of this valuable Styptic, the exhibition of which, in addition to its other properties, has been attended with such successful results in obstinate forms of Diarrhœa. Prospectuses of its use may be had on application.

Sole Agent for De Vere's Fluid Extract of the Red Paraguan Sarsaparilla, so highly recommended by the Faculty.—79, St. Paul's Churchyard, London.

For Varicose Veins and Weakness.—

SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, on a New Principle, pervious, light in texture, and inexpensive, yielding a permanent, efficient, an unvarying support under any temperature, without the trouble of lacing or bandaging. LIKEWISE, A STRONG, LOW-PRICED ARTICLE FOR HOSPITALS AND THE WORKING-CLASSES. ELASTIC NET CORSETS of the same beautiful Fabric. ABDOMINAL SUPPORTING BELTS, for both Sexes; those for ladies' use before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instructions for measurement, and prices, on application, and the articles sent by post from the Sole Manufacturers, POPE and PLANTE, 4, Waterloo-place, Pall-Mall. THE PROFESSION, TRADE, AND HOSPITALS SUPPLIED.

COUNCIL MEDAL.—GREAT EXHIBITION OF 1851, CLASS XXVIII., No. 76.

To the Medical Profession.—Charles

MACINTOSH and CO., 73, ALDERMANBURY, LONDON, and CAMBRIDGE-STREET, MANCHESTER, Patentees of the Vulcanized India Rubber, beg to draw the attention of the Medical Profession and the public generally to their DRAB VULCANIZED WATER PILLOWS and MATTRESSES, designed to alleviate the sufferings of bed-ridden patients and others. Price, from 10s. and upwards. Also, to the following, among many other articles of their manufacture. For particulars, refer to their Exhibition Catalogue, which may be had on application, gratis. Air-proof Beds and Mattresses, Hydrostatic Beds, India-Rubber Ring Beds, Bed-Sheets, Nursing Aprons, Sponging Baths, Chest Expanders, Breast Bottles, Truss Pads, Injection Bottles, Chemical Aprons, Sleeves, &c., Dissecting Gloves, Gas Bags, Elastic Woven Bandages, Belts, Stockings, &c. Tubing.

WORKS OF PERMANENT INTEREST AND UTILITY.

In 16 vols., imperial 8vo, (Supplement included,) price £9 12s. cloth lettered,

The Penny Cyclopædia of the Society for the Diffusion of Useful Knowledge. Edited by GEORGE LONG, A.M.

In 8 vols, imperial 8vo, price £5 12s., cloth lettered,

The Pictorial History of England; being a History of the People as well as of the Kingdom. Illustrated with many Hundred Woodcuts, and 104 Portraits Engraved on Steel. By GEORGE L. CRAIK and CHARLES MACFARLANE.

*** A COMPLETE INDEX to the WORK, by H. C. HAMILTON, Esq., of the State Paper Office. Price 10s. cloth.

In 4 vols, imperial 8vo, Price £2 10s. cloth lettered,

The Pictorial Bible; illustrated with Steel Engravings after celebrated Pictures, and many Hundred Woodcuts; with ORIGINAL NOTES. By JOHN KITTO, D.D., F.S.A.

THE NEW EDITION OF

Knight's Cabinet Shakspere is now COMPLETE.

It contains, in addition to Mr. Knight's careful collation of the PLAYS, Glossarial Notes, an Historical Introduction and Life, the Poems and Sonnets; with the various Portraits of the Author, and Illustrated Title-pages to the Volumes.——In 12 volumes, blue cloth, gilt edges, price 25s.

On the 1st of January, 1852. Part I., Containing Seven Portraits, and Biographies,

The Portrait Gallery of Distinguished Poets, Philosophers, Statesmen, Divines, Painters, Architects, Engineers, Physicians, Lawyers, &c. &c. With Biographies. Originally published by the Society for the Diffusion of Useful Knowledge.—To be Completed in Twenty-four Monthly Parts.

On the 1st of January, 1852. Part I., price 4s.,

A History of the British Empire during the First Half of the Nineteenth Century; being an Introductory Narrative of Events from 1800 to 1815, and the History of the Peace, from 1815 to the Present Time. By HARRIET MARTINEAU. Embellished with Portraits.—To be completed in Ten Monthly Parts.

LONDON: WM. S. ORR AND CO., AMEN CORNER.

IN TWO VOLUMES, BOUND IN CLOTH, PRICE 17s. EACH,

THE MEDICAL TIMES

FOR **1851**, CONTAINING

Lectures on Animal Chemistry. By H. BENCE JONES, M.D., F.R.S.
Delivered at the Royal Institution.

Lectures on Histology. By J. T. QUEKETT, Esq.
Delivered at the Royal College of Surgeons. Illustrated with Engravings from the Lecturer's beautiful Preparations.

Lectures on Public Health. By PROFESSOR GUY, M.D.
Delivered at King's College.

CLINICAL LECTURES,

By G. BUDD, M.D., F.R.S.
G. BURROWS, M.D., F.R.S.
W. JENNER, M.D.
BRANSBY COOPER, Esq., F.R.S.
W. FERGUSSON, Esq., F.R.S.

By W. LAWRENCE, Esq., F.R.S.
E. A. LLOYD, Esq., F.R.C.S.
R. QUAIN, Esq., F.R.C.S.
S. SOLLY, Esq., F.R.C.S.
E. STANLEY, Esq., F.R.C.S.

The Original Communications will be found to constitute a Repertory of Science of especial value to Practitioners in Medicine.

THE REPORTS OF THE LONDON AND PROVINCIAL

Practice of Medicine and Surgery, consist of Communications from Surgeons and Eminent men connected with the several Hospitals, and will be found to be a careful Selection of the most Important and Interesting Cases, frequently Illustrated by Engravings.

The Editorial Articles form another distinguishing feature of these Volumes Herein matters of more than ordinary importance are fully discussed, the interests of the Profession sedulously watched, and its honour and dignity asserted. Especial attention may here be directed to a Series of Articles relating to the Practice of Homœopathy, and its bearings upon the character and welfare of the Profession. Connected with this department of the Journal, will be found, a continued comment on the contents of the

Great Exhibition, in which the Instruments and Preparations relating to the Practice of Medicine and Surgery, particularly deserving of notice for their novelty or utility, are faithfully described. This series extends to twenty papers, and are communicated by a distinguished scientific observer.

Reviews: Under this head will be found a careful and faithful estimate of the character of the Medical Literature of the day; while the

Progress of Medical Science constitutes a careful digest of Contemporary Medical Literature, in which the special object has been to keep the Subscribers to the MEDICAL TIMES *au courant* with the advancing state of medicine and the collateral sciences.

LONDON: PUBLISHED BY JOHN CHURCHILL, 46, PRINCES-STREET, SOHO.

ORIGINAL LECTURES.

LECTURE IN CLINICAL SURGERY.

AT

Guy's Hospital.

By BRANSBY B. COOPER, Esq., F.R.S.,

Senior Surgeon to, and Lecturer on Surgery at, Guy's Hospital.

[Continued from page 384.]

HYDROCELE.

The conditions I have now described are not invariably concomitant; consequently, it is not always easy to distinguish hydrocele from certain other lesions connected with the scrotum, nor even indeed to ascertain the nature of the varieties and complications in which hydrocele itself may be implicated. After what I have said about the simple nature of hydrocele, it may seem an incongruity to admit, that more mistakes and accidents occur in its diagnosis and in the comparatively trifling operation of tapping, than in any other cases in surgery; such is, nevertheless, the fact; but it must depend upon want of proper care, owing to the apparent simplicity of the operation, rather than upon any positive difficulty in the steps of the operation itself.

A hydrocele may be mistaken for a hernia, diseased testicle, varicocele, or hæmatocele; or it may, in fact, be combined with any of these diseases,—a circumstance which would tend greatly to increase the difficulties of the case, both with respect to diagnosis and treatment. In addition to this, hydrocele itself is subject to varieties; it may be congenital, encysted, or diffused; the fluid may be contained in the whole cavity of the tunica vaginalis, as in the last case, or the latter may be divided, in consequence of adhesive inflammation, into two or more distinct cavities, each containing fluid, the whole constituting what is termed a multiform hydrocele.

The collection of serum may likewise not only be situated in the scrotum, but in the inguinal canal; or it may form a small tumour just below the external ring, between it and the testicle, varying, in this respect, from the common form of the disease. The knowledge that these modifications exist, is sufficient to show the necessity for a careful examination into all the circumstances, both constitutional and physical, attendant upon the formation of a tumour in the scrotum, before the diagnosis can be confidently formed, or appropriate treatment adopted. One of the most frequent deviations from the ordinary conditions of a hydrocele is absence of transparency, a peculiarity which tends, perhaps, more than any other, to render the diagnosis obscure and uncertain; while, in its presence, scarcely any other sign of hydrocele need be sought for, the transparency of the tumour being in itself a sufficient proof that it can contain nothing more than a translucent fluid. The fact of the tumour being transparent, although conclusive as to the disease being hydrocele, does not still, however, prove that the hydrocele is not complicated with some other disease; the surgeon must therefore examine closely into this point, and must likewise make himself acquainted with the peculiar character of the hydrocele itself. In the case I quoted at the commencement, the transparency of the tumour was evident at the first examination; but, as I have already said, this diagnostic mark is often either entirely absent, or at least very obscure. The circumstances which may interfere with the transparency of a hydrocele, are thickening of the skin, œdema of the cellular membrane, hypertrophy of the dartos and of the cremaster muscle, thickening of the tunica vaginalis, and opacity of the secreted fluid. I have seen several cases in which, owing to different circumstances, transparency was quite absent from the tumour. Any cutaneous disease in the scrotum may destroy the diaphanous condition of the skin of this part, and obscure the transparency of a hydrocele; but in that case, the appearance of the part externally would account for the loss of transparency; and if the other symptoms of the disease were present, the condition of the skin of the scrotum would scarcely produce much difficulty in forming a just diagnosis. Œdema of the cellular membrane may prove very difficult to distinguish from hydrocele, for in its general appearance the scrotum would then closely resemble hydrocele, with the single exception of wanting transparency. Upon a close examination of the case, it will, however, be found, that the patient manifests a general anasarca, that the tumour *pits* upon pressure, instead of being elastic, and that generally both sides of the scrotum are affected at the same time. I once had a private case in which there was even a distinct amount of transparency in the scrotal tumour; I therefore punctured it with the trocar; but a few drops only of serum exuded, and I found that I had been so far deceived by the transparency as to puncture an œdematous scrotum, in the belief that it was hydrocele. In this case I made small punctures in different parts of the scrotum, serum exuded, and the patient recovered from the disease. I have seen several cases of this kind, and in some of them the swelling had extended up one or both cords. Such cases should be first treated by puncture, to evacuate the fluid, and afterwards by constitutional remedies, to combat the anasarcous tendency. Hernia and hydrocele may be concomitant with each other; the latter being the consequence of some morbid change produced in the tunica vaginalis by the influence of the protruding intestine,—hypertrophy of the dartos and cremaster muscle often accompanying this complication,—so that the transmission of light through the structures covering the tumours is entirely prevented.

In 1810, Mr. Salt, of Dunmow, sent me a gentleman who had a hernia, and who consequently always wore a truss; in spite of this a tumour formed in the scrotum, and this, naturally enough, was looked upon by the patient as caused by his rupture. Upon examining the swelling, I found it perfectly isolated from the abdomen. I tried it by light in the usual way, but could discover no transparency. I, therefore, thought it right to explore the swelling. This I did by cutting down to the tunica vaginalis; and at the time I did this I was under the impression that the swelling was a hæmatocele, which might have been caused by the pressure of the truss. When I exposed the cremaster muscle, I found it, as well as the dartos, much thickened. Upon dividing the cremaster, I exposed the tunica vaginalis, and I perceived at once that this was distended with fluid. I laid it open, evacuated a quantity of the fluid usually found in a hydrocele,—performing what is called the operation by *incision*. The patient perfectly recovered.

In cases of difficulty, requiring exploration, I believe the mode of operating just described to be safer than any other, but it does not always produce a radical cure. In operating for hernia, I have frequently found a hydrocele of the tunica vaginalis connected with it, especially when the hernia has been congenital.

A common cause of absence of transparency in a hydrocele is thickening of the tunica vaginalis itself. In such cases, it must obviously be impossible to tell by mere examination whether the want of transparency proceed from thickening of the tumour, or from some alteration in the character of the fluid within the tumour. If (with the exception of transparency) every other indication of hydrocele be present, there can be no reason why we should not in these cases proceed at once to tap the tumour with a trocar; but if there be other circumstances to complicate the case, we ought to proceed by exploration, as I have just described. I had a patient in Phillip Ward, Guy's Hospital, who had a tumour of the scrotum which presented all the appearances of hydrocele; it had existed for twelve months; and he stated, that during its growth it had given him no inconvenience beyond that which arose from its weight; fluctuation was indistinct in this case, there was total want of transparency, and the weight of the tumour was unusually great in proportion to its size. I determined to evacuate the contents of the tumour by incision; I therefore proceeded cautiously to cut down upon the tunica vaginalis; I found it extremely thickened, highly vascular, and presenting altogether a very unnatural appearance; the evacuated fluid was like coffee-grounds. The patient stated, that he had struck the tumour about three months before, and that from that time its weight had much increased; probably it was then that the blood was effused, which gave to the fluid its peculiar colour and appearance. I have had other cases in which I found the tunica vaginalis very much thickened, particularly when an operation had been performed previously. Only a few days ago, I operated a second time upon the hydrocele of a gentleman, and, according to my invariable practice, examined the tumour before operating, to ascertain if the transparency were present; it was now, however, quite opaque, although it was transparent at the time of the first operation, all the other signs of hydrocele being present. I nevertheless proceeded

to tap the tumour. I now found the tunica vaginalis so thickened as to offer considerable resistance to the entrance of the trocar; but the fluid was precisely similar to that usually secreted in this disease, and to what I had drawn off in the first operation. In a case which I admitted, some time ago, into the hospital, there existed a large swelling in the scrotum, which I could not distinguish with certainty to be a hydrocele; I therefore opened the tunica vaginalis by incision, and let out a quantity of brownish fluid. The tunic itself was very much thickened, cartilaginous in many places, and at its upper part quite ossified.

Mr. Cock had a somewhat similar case, in which the tunic had become quite cartilaginous, and was thrown off by sloughing, after an incision had been made into it. Ossification of the tunic is not unfrequent; this would, of course, necessarily destroy the transparency in hydrocele; probably, wherever the formation of cartilage has commenced in the tunic, ossification would ultimately ensue. There is scarcely an hospital museum in London which does not contain numerous specimens of these peculiar conditions of the tunica vaginalis; that of the College of Surgeons is particularly rich in them.

The contents of common hydrocele are subject to changes which may entirely destroy the transparency of the fluid, and would, of course, tend as much to render the tumour itself opaque as any changes in its tissues could do. Ordinarily, this fluid is of a yellowish or straw colour, quite transparent, having a specific gravity of about 1020, which is rather less than that of the serum of the blood; it coagulates by heat, and by the addition of mineral acids, but less firmly than blood serum, in consequence of its containing less albumen; it contains also the saline matters of the serum. The quantity of fluid present in a hydrocele may vary from an ounce to several pints; I think six ounces may be taken as the average quantity.

Sometimes this fluid is quite turbid, and of a milky whiteness, resembling, indeed, a mixture of milk and serum: in acute cases, following external injury, the fluid will often be found of a reddish hue, or even as dark as coffee, according to the quantity of blood it contains. A large quantity of cholesterine is sometimes found in the fluid of a hydrocele; this substance presents a crystalline appearance upon the surface of the fluid after it has cooled; if this be skimmed off, it will be found to dissolve in boiling alcohol, from which it again separates in the crystalline form of large flat plates on cooling; these are insoluble in caustic potassa. Flakes of fibrin, portions of amorphous coagulated albumen, fatty matter, and even small cartilaginous bodies, are sometimes detected in the fluid of common hydrocele. When extraneous substances are found in the fluid, it is usual for the tunica vaginalis itself to have undergone some of the morbid changes I have already described, besides that which causes it to secrete the serous fluid; in chronic cases it will often be found, as I have already described, thickened, cartilaginous, or even bony; these conditions are, however, invariably attended by some constitutional derangement. From a reconsideration of all these abnormal conditions, it is clear, therefore, that the nature of the fluid and the condition of the tissues and testicle should all engage the attention of the surgeon; by these he will know whether the disorder is to be considered local or constitutional, the treatment being regulated accordingly.

Orchitis, from any cause, may lead to the formation of a hydrocele, and if the fluid secreted be transparent, the diagnostic mark will be sufficiently obvious from the tumour being opaque posteriorly and transparent anteriorly; but even should the swelling be opaque, the history of the case, the weight of the tumour in proportion to its size, and the characteristic pain of an inflamed testicle, will usually sufficiently explain the nature of the case. I have met with several such cases, and have rarely found it necessary to treat them as hydrocele, but employ the usual antiphlogistic remedies to allay the inflammation of the testicle, and then, by applying blue ointment and camphor with gentle pressure upon the scrotum, the inflammation and the hydrocele will generally disappear together. The disorder will not, however, terminate thus should the orchitis arise from a syphilitic taint, nothing but mercury will then effect a cure. Sir Astley Cooper has published a case in which hydrocele was combined with syphilitic orchitis; the fluid had been previously drawn off but had quickly re-accumulated, and the patient had consulted Sir Astley with the object of getting the hydrocele injected; but he, observing that there were present copper-coloured syphilitic blotches, recommended that the operation of injecting the tumour should not be attempted until the secondary symptoms were cured. Mercury was accordingly administered, and the consequence was, that the orchitis, cutaneous eruption, and hydrocele all disappeared together. I have never seen a case exactly resembling this. Mr. Roberts, of Finsbury-square, sent me a gentleman who had swelled testicle with hydrocele. I drew off the water, and treated the swelled testicle as if enlarged from common inflammation: the hydrocele quickly returned, but the disease in the testicle remained. The patient had no sore throat, nor eruption, nor any other indication of syphilis, although he stated that he had had a chancre four months before. I ordered him calomel and opium night and morning, which was continued until he became constitutionally affected by the mercury, when the testicle was cured and the hydrocele entirely removed. Three or four such cases have occurred in my practice, but, I must acknowledge, without equal evidence of syphilitic taint. When the important feature of transparency is absent from the tumour from any of the causes I have described, the diagnosis must be formed, either positively, from the presence of other signs of hydrocele, or negatively, by ascertaining that none of the diseases with which hydrocele may be complicated are the cause of the enlargement of the part; in that case the swelling can only be the consequence of hydrocele, or some anomalous disease. Under these difficult circumstances, the surgeon should proceed with great caution; for, although the tumour may consist of nothing more than a collection of water, the treatment can only be judiciously regulated by a complete knowledge of the exact position of the fluid and the peculiar structure affected. If an exploration be determined on, it must be pursued with great care, either by puncture with a grooved needle, or by making a careful incision in the tumour; the latter is, I think, the safer operation, as it may be performed under the guiding influence of the sight as well as of the hand. Even when the tumour is transparent, a difficulty may arise in consequence of the testicle being in an abnormal situation within the scrotum. It is usually situated behind and rather below the centre of the tumour; but it sometimes happens that the testicle is adherent to the tunica vaginalis reflexa, and is placed in front of the swelling. When the parts are in this condition the testicle is in danger of being pierced by the trocar; if the hydrocele be transparent, there is no excuse for such a catastrophe, for the exact relative situation of the testicle with the hydrocele may generally be discovered. If the swelling be opaque, the abnormal situation of the testicle can be ascertained by manipulation, as the tumour is fluctuating laterally and posteriorly, but not in front, at the usual point, where, indeed, the resisting hardness will clearly indicate the position of the testicle. I have punctured the tunica vaginalis posteriorly, or at the side of the testicle, in several cases, and I invariably seek for the diagnostic mark of transparency, even if I had tapped the patient before, as the operation may have been the very means of producing the adhesion of the testicle I have just described, and, without precaution, it is very likely to be wounded by the trocar.

On the 30th June, 1841, a patient was sent to me with a hydrocele: he had already been tapped. I examined the tumour, and found there was but little transparency, although, strictly speaking, something of this character could be distinguished. I proceeded to draw off the fluid. In introducing the trocar, I felt a very considerable resistance, and, when I withdrew the instrument, no fluid followed; the patient also complained of a pain in the part, which led me to believe that the testicle had been wounded. I immediately removed the canula, and, upon again examining the tumour with a light, I perceived that it was quite transparent at its posterior part. I then introduced the trocar in this transparent part of the tumour, and drew off seven ounces of fluid. I did not inject the tunic in this case, as I had at first intended; but, nevertheless, the patient was radically cured, and that, too, without suffering any ill effects from the accidental injury of the testicle. There are few operative surgeons who have not at some time fallen into the above error.

I have remarked, in a former part of my lecture, that hydrocele may be mistaken for hernia. I need scarcely say how grave an error this would be, particularly if the surgeon were to attempt an operation. Generally, I do not, however, think it very difficult to distinguish a common hydrocele,

under all circumstances, from a swelling caused by protrusion of viscera from the abdomen, especially from the circumstances, that, hydrocele being unconnected with the abdomen, does not receive those peculiar motions which are always imparted to the visceral protrusion, by contraction of the abdominal muscles, as in coughing; and that a very different character is discovered by manipulation between the contents of a hernial sac and those of a hydrocele, the latter being incompressible, resembling a bladder filled with water, whereas a hernia feels either soft and plastic, as it were, or gives the idea of being distended with gas. Hydrocele and hernia are not unfrequently combined, as in the case I have already described, of the little boy. It appears not unlikely, indeed, that hydrocele may induce hernia, by drawing down, and perhaps weakening, the parts about the scrotum. In treating hydrocele, when thus combined with hernia, the latter ought first to be reduced, and, even then, I think I should prefer not injecting the sac of the hydrocele, but merely content myself with drawing off the fluid. Although I do not distinctly perceive that danger could arise from throwing in the injection, still, as more or less inflammation follows this operation, I should take the safer ground, and only employ the palliative treatment.

I do not think that, practically, there is much danger of taking a hydrocele for varicocele, unless it be a congenital hydrocele. In fact, the character of varicocele is quite different to hydrocele when the tumour is handled, for, instead of appearing to be a closed sac filled with fluid, it is evidently caused by a mass of tortuous vessels from which the blood is free to flow or be expressed by slight force. It is true, in congenital hydrocele the fluid can be forced out of the tumour; but, in that case, the transparency of the tumour would be diagnostic of its being hydrocele. If there be insuperable difficulties in distinguishing the nature of the swelling in the scrotum by ordinary examination, careful exploration ought to be resorted to, exactly as I have already described. This is the only plan for the surgeon to follow, if he desire to escape the dangerous contingencies which would be attendant upon any other active method of treatment.

[To be continued.]

ORIGINAL COMMUNICATIONS.

OBSERVATIONS

ON THAT PORTION OF THE

"SECOND REPORT ON QUARANTINE," BY THE GENERAL BOARD OF HEALTH

WHICH RELATES TO THE YELLOW FEVER EPIDEMY ON BOARD H. M. S. ECLAIR, AND AT BOA VISTA IN THE CAPE DE VERDE ISLANDS.

By J. O. M'WILLIAM, M.D., F.R.S., R.N.
Medical Inspector H. M. Customs.

I had imagined, that all doubt regarding the real nature of the epidemy that prevailed at Boa Vista, during the years 1845-6, had long since been at an end; and it can scarcely be said, that this conclusion was arrived at either hastily or unwarrantably.

My Report "On the Fever at Boa Vista," was delivered to Sir William Burnett a few days after my arrival in England from the Cape de Verdes, in the month of September, 1846, and was laid before the Lords Commissioners of the Admiralty on the 30th October, of the same year, with a letter from the Director-General, in which he stated, that he "could not arrive at the conclusion, that the fever was occasioned by the intercourse with the Eclair."

The Report, and the letter of Sir William Burnett, having been presented to the House of Commons, in pursuance of their address of the 16th March, 1847, were ordered to be printed. And both documents being thus brought before the Profession, were very prominently and fully reviewed in the leading medical journals of the United Kingdom, of France, and of America, the greater number of which had been hitherto opposed to the contagion of yellow fever.

On the Boa Vista question, however, there was an unanimity of opinion, almost, if not wholly, unprecedented in a case of this kind; for, with one very qualified exception, the justice of my conclusions was confirmed by the united voice of the medical Press.(a)

I need scarcely add, that Sir William Pym, the Superintendent-General of quarantine, adopted the views contained in my Report, with the exception of that in which I considered the yellow fever of the Eclair to be an exaltation of the common endemic remittent of the west coast of Africa.

Upon the presentation of the Report of Dr. King "on the Fever at Boa Vista," to the House of Commons, in return to their address of February 4, 1848, the discussion of the subject in the public journals was renewed, and my Report was again subjected to a severe sifting. Dr. King's conclusions were wholly opposed to mine, although our main facts were the same. His views met with no sympathy (so far as I have seen) from the public press, as they were universally declared to be untenable upon the evidence which he himself had supplied. Instead of burdening this communication with extracts from the various reviews, I shall only make the following quotation from a journal that has consistently opposed the doctrine of contagion as applied to yellow fever, which will serve to convey the general opinion of the press regarding Dr. King's Report:—

"After the most careful examination of the subject, as presented by these several documents, we are constrained to confess very candidly, and, we admit, somewhat reluctantly, that Dr. King has failed in his attempt to invalidate the conclusions of Dr. M'William, logically deduced from a connected series of well-defined facts. If it be possible to prove the communication of a disease by contagion, the facts presented by this gentleman, and not disproved by Dr. King, prove, that the fever which occurred in Boa Vista was introduced by the sick from on board the Eclair, and communicated from individual to individual, until it finally extended to the mass of the population."(b)

It even appeared, that Sir William Burnett could discover no support in Dr. King's Report to his dissent from my conclusions, as it was not, on being presented to Parliament and printed, accompanied by any comments from the Director-General.

On the 10th of August, 1849, a Board of medical officers was convened by order of His Grace the Commander-in-Chief, for the purpose of investigating and giving an opinion on each of the following points:—

"1st. Is yellow or Bulam fever a distinct disease, or only an aggravated form of the marsh or remittent fever of warm climates?

"2nd. Does one attack of yellow, or Bulam fever, give, like small-pox, immunity from a second attack, except in very rare instances?

"3rd. Is yellow or Bulam fever a contagious disease?

(a) "We have adopted the evidence of Dr. M'William, because we have felt bound to give credence to what is honestly and candidly stated by an observer, who must have felt the immense responsibility that rested upon him in drawing up his Report.—If we had wished to have tried a great experiment on this subject, with all available precaution, and with all the aids against fallacy that imperfect human reasoning can furnish, it would have been difficult to have devised any more complete and conclusive than that which accident, or, we should say—if it be not profane to judge of the arrangements of the universe—a providential accident, has furnished us in the case of Boa Vista."—*British and Foreign Medico-Chirurgical Review*, Vol. I., page 60.

"We have carefully examined the evidence collected by Dr. M'William, and we now unhesitatingly assert, that the above conclusions flow as legitimately from the premises, as moral reasoning will admit of."—*Dublin Quarterly Journal of Medical Science*, No. XV., p. 192.

"Upon a review of all the evidence adduced in the Report before us, there cannot be a reasonable doubt as to the contagious character of the disease that prevailed at Boa Vista: nor do we think it will be questioned, that the infection was introduced into the island by the sick landed from on board the Eclair."—*Hays's American Journal of the Medical Sciences*, No. XXVIII., p. 427.

There is not room for further extracts, but the exception must not pass without notice:—

"Although we are not convinced by Dr. M'William's reasoning as to the origin of the Boa Vista epidemic in the Eclair, we are, nevertheless, bound to acknowledge that he has exhibited very great knowledge and practical acumen throughout the investigation, and has drawn up a Report which testifies strongly to his abilities, and redounds greatly to his credit.

"——The symptoms and subsequent progress of the epidemic, after its outbreak in Beira Row, clearly demonstrate its identity with yellow fever, and its infectious nature.

"——Dr. M'William appears clearly to have traced the transmission of the fever to the inhabitants of the other villages in Boa Vista, either by communication with the sick, or by the arrival of persons under the influence of the fomites of fever."—*Lancet*, New Series, Vol. II., pp. 496—498.

(b) Hays's American Journal of the Medical Sciences, No. XXXIII. p. 141.

"4th. Is yellow or Bulam fever capable of being imported?"

The Board was consituted as follows:—

President, Dr. And. Smith, Deputy-Inspector General of Hospitals; Dr. Thomas Spence, staff-surgeon, 1st class; John Millar, Esq., staff-surgeon, 1st class; Dr. W. H. Burrell, staff-surgeon, 1st class; Henry Pilleau, Esq., staff-surgeon, 2nd class.

The Board assembled on the 10th of August, 1849, and continued, by adjournments, to the 16th of April, 1850.

At the first sitting it was resolved,—

"First, To attentively read and examine all official or other documents available and likely to elucidate the subject to be investigated.

"Secondly, To receive oral evidence of army medical officers and other persons competent to furnish information on the points in question.

"And, lastly, After having accomplished the foregoing, then to determine the time which will be necessary to enable the Board to form their opinion, and furnish their replies to the questions proposed."

One hundred and twelve sittings, averaging three hours each, were occupied in reading documents, published opinions, and receiving oral evidence; and two months were found necessary for the purposes specified in the last resolution.

The respective opinions of the President and members were found to be as follow:—

As regards the first question,—

"The President and three members, namely, Dr. Spence, Mr. Millar, and Mr. Pilleau, are of opinion, that the yellow or Bulam fever is a distinct disease, etc.

"The fifth member, Dr. Burrell, is of opinion, that the yellow or Bulam fever is an aggravated and occasional form of the ordinary fevers, continued, remittent, and sometimes intermittent, etc. etc."

As regards the second question,—

"The President and one member (Mr. Pilleau) consider, that one attack of yellow or Bulam fever does give immunity from a second attack, except in rare instances. A third member (Dr. Spence) is of opinion, that an attack of yellow or Bulam fever protects the constitution very greatly from liability to a second; but the exact extent requires further observation. A fourth member (Mr. Millar) considers, that one attack of yellow fever does give, like small-pox, immunity from a second attack, except in very rare instances. And the other member (Dr. Burrell) is of opinion, that an attack of yellow or Bulam fever, like length of residence, enables the constitution to resist, to a considerable extent, a recurrence of fever in the same form, but gives little or no protection against what he considers other forms of the same disease, or those which attack the acclimated."

As regards the third question,—

"The President and two members (Dr. Spence and Mr. Pilleau) are of opinion, that yellow or Bulam fever has frequently manifested a contagious power; and that on many occasions the contagious power, if in existence, could not be detected by the most careful observation. One member (Mr. Millar) is of opinion, that yellow or Bulam fever is a contagious disease. And the other member (Dr. Burrell) considers, that nothing sufficient has been adduced before this Board to determine affirmatively a question of so much importance to humanity and science; and believes the yellow fever to be absolutely and universally non-contagious."

As regards the fourth point,—

"The President and three members (Dr. Spence, Mr. Millar, and Mr. Pilleau) are of opinion, that yellow or Bulam fever is capable of being imported. The other member (Dr. Burrell) is of opinion, that yellow or Bulam fever is not capable of being imported."

(Signed by the President and Members.)

[The above contains the substance of the proceedings of the Board.]

On the 31st December, 1850, the Royal College of Physicians of London delivered a Report to the Lords of Her Majesty's Most Honourable Privy Council, respecting the Bulam, or yellow fever, which had been drawn up by the President and Fellows of the College in consequence of a communication from their Lordships.

The points investigated by the College were as follow:—

"1. As to the Bulam fever being *sui generis*, and distinct from remittent or the marsh fever of warm climates.

"2. As to its being an infectious disease; that is, communicable from person to person, and likewise capable of being imported.

"3. As to the non-liability of persons to a second attack of that disease.

"After a very careful consideration of all the facts and arguments adduced on both sides, with reference to the first question proposed, the College are of opinion, that sufficient grounds have not been laid for stating, that "yellow fever" is a disease *sui generis*.

"With regard to the second question, it appears to the College to be sufficiently proved, that this disease is, under certain circumstances, infectious, and, consequently, that it may be imported.

"The principal circumstances under which the infectiousness of this disease is likely to be developed, would seem to be a high temperature and moisture of the atmosphere, particularly in unhealthy seasons, and when the influence of these causes is aggravated by local insalubrity of site, and by the absence of free ventilation.

"That the disease has been in some instances imported, the history of the epidemic fever which occurred in Her Majesty's ship Eclair, and at Boa Vista in 1845, affords conclusive evidence.

"The third question proposed respecting the non-liability of persons to second attacks, does not admit of being settled in a decided manner. Strictly speaking, there is no disease of which it can be affirmed, absolutely, that one attack renders a person insusceptible of a second.

"The College are unwilling to conclude their Report without strongly recommending to their Lordships, that, on any future appearance of this formidable malady, persons should be sent out, thoroughly qualified by education and by habits of observation, to collect evidence on the important questions which have now been proposed to the College. This was done in the case of the Eclair, and most valuable information was thus obtained.

(Signed)

"Francis Hawkins, M.D., Registrar.

"Royal College of Physicians,
December 31, 1850."

The latest investigation into the circumstances connected with the epidemy of the Eclair and Boa Vista is that which occurs in the "Second Report on Quarantine," recently presented to Parliament by the General Board of Health. The professed object of this investigation is to set aside the conclusions of the Royal College of Physicians and those of the Committee of Army Medical Officers, as well as the opinions of the Medical Press in this country and elsewhere; for, at page 189, "Report on Quarantine," it is stated, that, as "the case of the Eclair, and the history of the epidemic fever which occurred at Boa Vista in 1845, have been declared by high medical authority to afford 'conclusive evidence that yellow fever is sometimes imported,' it will, therefore, be necessary to give a careful examination of the circumstances relative to that epidemic;" and at pp. 115-116, "A consideration of these circumstances has satisfied most of those who have inquired into the case, that the arrival of the Eclair at Boa Vista with fever among her crew, and the almost contemporaneous occurrence of a similar disease on the island, were mere coincident events."

There is, in this language, coming as it does from a Board consisting of two lay members and one medical member, a tone of assumption, if not of disrespect, towards the Royal College of Physicians, the Committee of Army Medical Officers, and others, (who from their education, habits, and professional eminence, must be held as at least equally competent with the General Board of Health to make a "careful examination" of the occurrences in the Eclair and at Boa Vista,) unjustifiable under any circumstances, but peculiarly unbecoming of any public Board when making allusion to other Boards, more especially when the respective positions and acquirements of the parties in question are duly considered.

When I first heard that yellow fever was to form the subject of this Report, I could not (judging from the first Report on Quarantine from the same Board) but expect that the doctrine of contagion would be unsparingly, if not unreasonably assailed. I was not, however, prepared for the omission, in a public document, of facts indispensable to a just and correct exposition of the case, or for the numerous mis-statements which are to be found in that part of the "Report on Quarantine," which professes to treat of the Eclair and Boa Vista epidemy.

At the very outset of any inquiry into the epidemy at Boa Vista, there is one point that demands a clear and satisfactory adjustment, viz., the condition of health of Boa Vista, and of the other islands of the Cape de Verde groupe, previously to the arrival there of the Eclair, with her crew suffering from yellow fever. It is further indispensable, to ascertain with precision the state of health of those other islands after the arrival of the Eclair, and the invasion of Boa Vista by the same disease; inasmuch as it is stated, in the "Second Report on Quarantine," page 110, that "in the adjoining island, Porto Praya (San Jago), there was yellow fever while the ship (Eclair) was at Boa Vista. Captain Simpson states, that it "recurred in the following year at Porto Praya, is common there at times, and quite endemic."

And doubtless, could it have been proved, that yellow fever had broken out on San Jago, independently of any source of importation, contemporaneously with the appearance of the same disease at Boa Vista, then there would have been grounds for supposing that it might also have originated spontaneously at Boa Vista, and that the arrival of the Eclair with yellow fever, and the outbreak of this disorder at the latter island, were mere coincident events.

By the concurrent testimony of all I interrogated on the subject,—and they included the most intelligent among the natives and Europeans at the Cape de Verde, and of all who were afterwards examined by Dr. King,—Boa Vista was quite healthy before the arrival of the Eclair.(a)

It is equally certain, that yellow fever had never before been known at Boa Vista—at all events, within the memory of any person living.

The assertion, that yellow fever was at Porto Praya (San Jago) at the period of the arrival of the Eclair at Boa Vista, or during the prevalence of the epidemy on the latter island, is so completely refuted in the documents in the possession of the authors of the "Report on Quarantine," that I cannot help expressing my astonishment that they should have repeated it in their Report.

In my Report (p. 108), I took leave, after due inquiry at the Cape de Verde, to deny the correctness of this statement, which is contained in Dr. Stewart's Report, ("Admiralty Correspondence," p. 88.) (b) At p. 14 of the "Remarks on Dr. King's Report," I cited the testimony of Dr. Antonio José Nunes, Surgeon of the Artillery at San Jago, (of which island Porto Praya is the capital,) who came direct from that place to Boa Vista during the prevalence of the yellow fever epidemy there. Dr. Nunes pronounced distinctly, that the disease at Boa Vista was yellow fever, and "*quite different from those fevers which he saw every year at Porto Praya.*"(c) This, then, is the evidence of an officer who came to Boa Vista from the very spot where yellow fever is alleged to have prevailed at the time, but of which no notice is taken in the "Report on Quarantine." Again, in my "Remarks on Dr. King's Report," p. 10, there is an extract of a letter from the Governor-General to Dr. King, dated December, 1846, in which His Excellency says: "Never a fever with equal symptoms visited these islands before the arrival of the unhappy Eclair at Boa Vista."

The addition of strength to the evidence already published, refuting the existence of yellow fever at Porto Praya at the period in question, is scarcely necessary. I may, however, be allowed to quote the following passage from a letter addressed to me by the late Mr. Macaulay, Commissioner, Judge, etc., at Boa Vista, dated at San Nicolas, March 30th, 1846. Dr. Stewart says, p. 4,(d) "*In the adjoining island, Porto Praya, there was yellow fever while the Eclair was at Boa Vista.*" This statement is entirely erroneous. There neither is, nor has been, one case of yellow fever at San Jago, or any of the islands, except at Boa Vista, and then only since the departure of the Eclair."

With regard to the statement of Captain Simpson, of the Rolla, it is quite evident to me, that he has confounded the endemic remittent of Porto Praya with yellow fever. That there could have been no yellow fever there at the time stated by him, has been already shown by the testimony of the Governor-General, as well as by that of the surgeon of artillery at Porto Praya.

If further proof of the immunity of Porto Praya from yellow fever, at either of the periods in question, were wanting, it is to be found in the following extract from a letter lately received from Mr. George Miller, one of the best educated, most intelligent, and keen observers whom I have ever met. He says:—"With respect to the statement, that yellow fever prevailed at San Jago, while the Eclair was at Boa Vista, or while the fever raged there, I am in a position to say positively and most unequivocally, that it is untrue. I was at Porto Praya frequently during the period of the Boa Vista calamity; and it so happens, that I was also there during the whole stay of Captain Simpson, of the Rolla. From 1838 to 1850, I visited Porto Praya at least twice a-year; sometimes, indeed, three and four, and even five times a-year. I never saw, nor have I ever heard of, a case of yellow fever there; and I am as morally certain that I should have heard, had any such case existed, as I can be of anything. Indeed, there is no record of yellow fever ever having prevailed at San Jago, or at any of the other islands, except at Boa Vista, in 1845-46. I was at some pains to satisfy myself on this head in 1846, when I visited every one of the islands, except St. Vincent. I made it my business personally to seek information on this matter, from the oldest and most intelligent of the inhabitants of each of the islands. I could learn of small-pox being imported in slave-vessels, and of the prevalence, in particular years, of endemic remittent; but every one ignored the existence ever of yellow fever and black vomit. Intermittent fever is common, more or less, to all the Cape de Verds; and every year, about the second month of the rains, a few cases, in some part or other of these islands, manifest themselves."

I think it is clearly evident, that the statement in the "Report on Quarantine," regarding the alleged prevalence of yellow fever at Porto Praya, when the Eclair arrived at Boa Vista, or while the same fever devastated Boa Vista, must fall before the force of truth; and as the authors of that Report declare the *assumed fact* of the existence of yellow fever at Porto Praya, at the periods in question, to be "most material to a right understanding of this whole subject," they cannot but consider the *demonstrated fac of it-non-existenec* at those periods as equally importan to that desirable end.

No notice whatever is taken, in the "Report on Quarantine," of the case of the lamented Dr. M'Clure, who was seized with his fatal illness (fever, with black vomit) the day (Sept. 13, 1845) on which the Eclair and Growler sailed from Boa Vista. This excellent and devoted medical officer, recently promoted after service on the west coast of Africa, was on his way home in the Growler when that vessel arrived at Boa Vista, on the 6th September, and found the sick crew of the Eclair landed at the fort in the small island. On the 8th, he relieved Mr. Maconchy, the surgeon of the Eclair, now almost worn out by his overwhelming duties among the sick at the fort. On the 13th, Dr. M'Clure was attacked with fever, having, for the first time, been on board the Eclair for a few minutes on the previous day, the sick being then re-embarked. In the previous March, the Growler had left the Coast for the Cape de Verd Islands, where the health of the ship's company was recruited, and had returned to the Gallinas and Sherbro' in April, and remained there until July, cases of fever continuing to occur from the consequences of exposure. The crew of the vessel had been quite healthy, with the exception of the gunner, and part of a boat's crew suffering from the common fever of the Coast, for between two and three months before her arrival at Boa Vista.

Sir William Burnett, who cannot be charged with any undue leaning to contagion, clearly admits, that the attack of Dr. M'Clure was due to his intercourse with the sick of the Eclair at the fort. The Director-General thus expresses himself, (when speaking of the fort,) in a letter addressed to the Secretary of the Admiralty, (Correspondence," p. 55):—"It is necessary I should add, that a fever, not originally of a contagious nature, may become so, when

(a) "It does not appear from the statements of the people, whether of the better or the lower classes of society, that fever was prevalent at Boa Vista at the time the Eclair arrived there, in August, 1845; and they are equally positive as to the healthiness of the other islands."—Dr. King's Report, p. 3.

(b) The Report of my friend, Dr. Stewart, was written in London; and upon what grounds he made this statement, I am not yet aware. My refutation of it was grounded on information obtained at the Cape de Verds, and the names of my authorities are given at p. 108, "Report," and at p. 14, "Remarks."

(c) Dr. Nunes's letter is dated at "Villa da Praya." Cape de Verde, March 6, 1847. He adds: "The fevers of Porto Praya take place only in the rainy season, and they are always the same, intermittent or remittent."

(d) Manuscript Report of Dr. Stewart, given me before I proceeded to the Cape de Verde.

the sick are crowded together in a small, ill-ventilated place. *Hence the attack* of Dr. M'Clure," etc.(a)

It is now time to proceed to the consideration of the cases of the two European soldiers at the fort, as they constitute the first link in the chain of evidence connecting the outbreak of yellow fever at Boa Vista with the sick of the Eclair. At page 102, "Report on Quarantine," these attacks are thus accounted for: "Two European soldiers lately arrived in the colony, and, therefore, peculiarly predisposed to an attack of endemic fever, go from Boa Vista, which at that time was healthy, to a confined, unventilated, overcrowded, and filthy spot, on another island, where fever was raging to such a degree, that, within the space of three weeks, there had occurred not less than 60 attacks, and 33 deaths, in a crew consisting, on the arrival of the ship, of 117 officers and men. We submit, that this is no evidence of the propagation of disease by a specific contagion. On the contrary, it is the ordinary production of it by its ordinary cause; namely, exposure to a polluted atmosphere, the pollution being, in this instance, excessive from overcrowding," etc.

Now, in the first place, it is not quite correct to say, that the soldiers had lately arrived in the colony, for they had been thirteen months in the Cape de Verds, and had, consequently, passed through all the changes incident to the annual rotation of the seasons. However, granting, as I have elsewhere done, their "predisposition to an attack of endemic fever," it must at the same time be recollected, that yellow fever, with which they were attacked, and of which they died, was not an endemic of Boa Vista, this disease having never, within the memory of man, been known there before the arrival of the Eclair. The epidemical constitution of the atmosphere is not invoked by Dr. King earlier than the end of September or beginning of October; nor is it assumed, in the "Report on Quarantine," to have had an earlier existence; for the seizure of the soldiers is attributed, not to an endemic, but to an accidental cause; namely, their breathing a local atmosphere "excessively polluted" by overcrowding, etc.

Now, it is fully admitted, that the place was crowded by a ship's crew labouring under yellow fever, which had certainly not been generated, although there is reason to believe that it had become more malignant in character, there. It is admitted, that the soldiers came from a healthy atmosphere to another atmosphere rendered unhealthy, not by a general, but by a local, source of pollution; namely, the congregation of persons labouring under yellow fever, and that the result was, that they (the soldiers) became affected with the same disorder. It is denied, in the "Report on Quarantine," that the attack of these soldiers affords any "evidence of the propagation of a disease by a specific contagion; but it is allowed, that their seizure was owing to to their inhaling the atmosphere, rendered morbific by the sick crew living; and it may be added, dying at the fort: in other words, by exhalation or effluvia proceeding from their bodies. If these admissions be adopted by the authors of the "Report on Quarantine," nothing further seems necessary to prove the communication of the disease to the healthy soldiers by the sick crew of the Eclair. If, on the other hand, they be denied, then it is incumbent upon the authors of the "Report," not only to prove that yellow fever was an endemic of Boa Vista, but that the endemial cause was in operation at the time the soldiers were attacked, or that the soldiers would have been seized with yellow fever, had the Eclair's crew been congregated as they were at the fort, but without any such disease prevailing amongst them.

The next link in the chain, the attack of the negro soldier, is accounted for in the "Report on Quarantine," in the same manner as are the attacks of the European soldiers.

Before advancing to the third link in the chain, (the attack of Anna Gallinha) it seems advisable to take some notice of the state of the weather before this period, and of a murrain among the cattle at Boa Vista, alleged to have existed coincidentally with the epidemy on that island.

(a) "Dr. M'Clure went direct from the Growler to the fort, without having gone on board the Eclair," (he was on board a few minutes.—J. O. M'W.) "and at once entered on his medical duties among the sick located there. In less than three days he was attacked with the disease,—pretty clear evidence, notwithstanding his having been at Sierra Leone, that the fever had become contagious.—*Origin, Spread, and Decline of the Epidemic Fevers of Sierra Leone, etc., etc., etc., by Dr. Bryson, p.* 134.

In my Remarks on Dr. King's Report, p. 6, I stated that, from the evidence of Mr. Macaulay, the Consul, Mrs. Pettingall, and others, the weather was never more beautiful than at the period of the Eclair's arrival at Boa Vista. On the day of the sailing of the Eclair and Growler (September 13th) the weather is described in the diary of the Consul, "as warm in the sun, but with cool breezes. The weather has been of this description from the arrival of the Eclair, and to the date of her sailing we had no rain." By the same diary, no rain fell until the 5th of October. Captain Buckle (of the Growler,) also says, the "winds were N. E. to N. by E. sky always b. c. A little rain fell once or twice during the night while we were there." But, as has been already observed, as neither in Dr. King's Report, nor in the "Report on Quarantine," is an "epidemical condition of the atmosphere," assumed to have existed at this period, this part of the subject does not require further discussion. (a)

By the time Anna Gallinha was attacked (October 12th,) "much rain had fallen, the weather had become more hot, and in short there now, (but not before this,) existed the recognised elements for malarious evolution.—(*Dr. M'William's Remarks, &c.* p. 9.)

It has been seen, that in the "Report on Quarantine," the attacks of the European soldiers, and that of the negro soldier at the fort, were attributed to the crowding of the crew of the Eclair. Anna Gallinha's attack, however, now that the rainy season had set in, is ascribed partly to the exhalations blowing upon the part of the town where she resided, (Beira,) from "a stagnant pool of salt and fresh water," and "from a locality resorted to by many of the people when obeying the calls of nature;" and partly to the "epidemic constitution of the atmosphere," invoked also, at this time, by Dr. King, and the authors of the "Report on Quarantine."

Now, I have elsewhere stated, ("Remarks," etc., p. 9,) that the chief expanse of stagnant water consequent upon the rains at Boa Vista, is not to be found at Beira, where the fever broke out, but immediately behind the main body of the town. As regards the other source of atmospherical pollution, the principal resort of the people for the purpose alluded to, is also behind this part of the town. In fact, in many parts of the town itself, there are receptacles of the same nature.

With respect to the epidemic constitution of the atmosphere, (a term exceedingly convenient, but more adapted to retard than to advance our knowledge of the causes of epidemic diseases,) its assumed existence during the prevalence of yellow fever at Boa Vista, is supposed, in the "Report on Quarantine," to derive support from a disease having at the same time, as it is alleged, proved fatal to numbers of the cattle on the island.

I can only say that, during the months of April, May, and June, 1816, I examined every part of the island, on one occasion, with John Jamieson and my two negro attendants, sleeping in the open air during four successive nights, making the circuit of its entire coast, traversing it in every direction, and, with my barometer, ascending and measuring the height of its principal mountains. I was in every village,—and some of the villages I visited very frequently,—and I entered a great number of houses in each village. Nowhere (and no place could escape me) did I see any evidence of this supposed wholesale destruction among the lower animals. The remains of a very few cattle were, indeed, seen; but, on inquiry, I was told that every year, at the end of the dry season, and after the setting in of the rains, some cattle were lost. At the former period, from actual exhaustion from want of food; a circumstance not to be wondered at, considering the extreme aridity of this long season, which destroys every blade of grass, and every patch of vegetation, that can find subsistence in this barren, volcanic region; at the latter period, the deaths among the

(a) Concerning the rain and the state of the weather, extracts are taken at pp. 110 16 of the "Report on Quarantine," from the letters of the English Consul and of the "British Judge," (the late Mr. Macaulay.) I recommend those who wish to know what were the real opinions of those functionaries regarding the cause of the fever, to read their letters throughout, (pp. 35 to 40, "Correspondence on the subject of the Eclair,") as also the extract from Mr. Consul Rendall's letters at pp. 9, 10 of my Remarks.

No one capable of appreciating the amount of labour involved in making, correcting, and recording barometrical, thermometrical, hygrometrical, and other observations three times every twenty-four hours while I was at Boa Vista, will readily suppose me likely to neglect the necessary inquiries regarding meteorological phenomena at this or any other period of the epidemy.

cattle are attributed to their over-feeding, in this exhausted state, on the rank green vegetation which springs up even there in the plains and water-courses with that rapidity and luxuriance which is known only in the tropics.(a)

I am thus particular regarding this supposed murrain during the prevalence of yellow fever at Boa Vista, because, in a note appended to the Report on Quarantine (p. 317), it is with very questionable taste insinuated, that I had purposely omitted all mention of it, either in my "Report" or "Remarks."

To return to the case of Anna Gallinha. I think I have shown satisfactorily, notwithstanding the statement of Dr. King to the contrary, that this woman was a constant visiter of Miguel Barbosa and his companions while they were in the house at Beira, (Vide Evidence of Miguel Barbosa, pp. 22, 23; of Joana Terceira, p. 28, "Dr. M'William's Report.") But, says the "Report on Quarantine," p. 103, "supposing Dr. M'William's account to be the correct one, it is surely in the highest degree improbable that this attack of Gallinha could be owing to contagion from a man whose illness was so slight, that it did not confine him to his bed for a single day, and which was incapable of infecting his companion, who was constantly with him night and day, when there were such obvious local causes to account for her illness."

It is quite true, that the illness of Miguel Barbosa was slight while he was at Beira; but the history of all contagious disorders abundantly proves, that slight cases have the power of reproducing the same disease in others in a severe degree, and *vice versâ*. Miguel Barbosa's companion was complaining; but, even supposing that he had not been unwell, it must be held in mind, that Anna Gallinha was a European, and, therefore, a much more susceptible subject than he, who was a negro.(b) Although, with respect to the "obvious local causes," as I have already said, "there now (but not before this) existed the recognized elements for malarious evolution," still, I hold, that the Beira Row is less exposed to the source of such evolutions than other parts of the town, in which the other sources of pollution also exist, in much greater abundance. Even supposing the Beira Row to be as bad as the authors of the "Report on Quarantine" desire to make out, it must be considered as a circumstance not a little extraordinary, that this same state of things should have existed probably for half a century, without giving rise to yellow fever until this period, which had been preceded by some rather remarkable occurrences, namely, the arrival of the Eclair at the island with yellow fever, the death of two soldiers belonging to Boa Vista, at the fort, from the same disease; the arrival at Beira of the two sick soldiers from the place where the sick of the Eclair had been lodged, and where they (the soldiers) had already lost their two comrades from yellow fever. It is somewhat strange, to say the least of it, that this disease should further mark for its first victim in Boa Vista, the woman who cooked and performed other offices for those soldiers.

"At this point," according to the "Report on Quarantine," p. 103, "the presumed chain of evidence stops; there is nothing connecting the illness of Gallinha with the next case," etc.

[To be continued.]

(a) John Jamieson, the Consul's storekeeper, now in London, says, "the cattle did not commence dying until after the fever had, in a great measure, left the island. The disease of the cattle every year is caused by the great want of pasture before the rains, and from the overeating of the poor exhausted animals after the rains." "I saw no change in the number of locusts that visited the island in 1845-6, from any other year. More cattle than usual died at the end of the dry season in 1846, but not in 1845." "I was on the island of Boa Vista nine years."

(b) The following facts, arising out of the Eclair and Boa Vista epidemy, may be useful at this period, as well as at other periods of the inquiry;—

On the island of Boa Vista the ratio of mortality amongst Portuguese Spaniards, and French exposed to the fever, was	...	...	...	...	1 in 2·28
English and Americans	...	...	...	...	1 in 1·6
Native population—Slaves	...	...	...	...	1 in 33·1
Free	...	...	...	...	1 in 11·6

Mr Gardner, in an interesting account of a Small-pox Epidemy at Mauritius in the year 1840, read before the Epidemiological Society, states, that the disease was on this occasion introduced into the island from H.M.S. Lily, with between two and three hundred slaves on board, among whom small-pox prevailed, and for which she was performing quarantine in the roads, through the medium of a man who had been in a boat alongside, watering the vessel. The case of this man, who introduced this severe epidemic into the island, and which destroyed thousands of persons, was so slight, that it was for some time doubtful whether it were really a case of small-pox. Twelve medical opinions were taken upon the case, and six considered it to be true variola; the others were of opinion that it was a case of varicella. Mr. Gardner was then referred to, and he declared the case to be one of small-pox; and the authorities at once placed the house in which this man lived in strict quarantine. Ten or twelve days after, a woman who had resided in the same house had the disease. Others living near soon took it, and it ultimately spread from this point over the whole island. The man at first declared he had not been near the Lily; and how he contracted the disease was for some time a mystery. He at last confessed to having been alongside the Lily, and, while there, to having taken some food from a sailor through a port-hole. Quarantine had kept small-pox out of the island upwards of thirty years. Had the channel of communication in this instance remained undiscovered, would it have been said, (one is inclined to ask, with the case of Boa Vista before us,) that, on this occasion, there was a *generatio de novo* of the small-pox virus, and that the outbreak of the epidemy at Mauritius and the arrival of the slave-laden vessel with that disorder were mere coincident events?

ENTROPIUM:

ITS PATHOLOGY PROVED TO DEPEND ON MUSCULAR ACTION; THE SOURCE OF THE MUSCULAR POWER.—A NEW METHOD OF OPERATING.

By HAYNES WALTON, Esq., F.R.C.S.,

Surgeon to the Central London Ophthalmic Hospital, and to St. Mary's Hospital, Paddington.

Entropium, or turning in of the eye-lid, may arise from various eccentric causes, including all kinds of wounds, injuries, and abnormal growths. There is, however, so little remarkable in this state of the affection, so little to be said in the way of generalization, and the treatment is always so obviously in accordance with the general principles of surgery, that I pass it over, and proceed to the common form, idiopathic entropium, and about which there are such numerous theories and dissimilar views, both as to mode of production and treatment.

Of the many reputed origins of the derangement, some are obsolete and need not be recounted; but several others, such as relaxation of the skin of the lid, thickening of the palpebral conjunctiva, shrinking of the tarsal cartilages, occasional faulty action of the orbicularis palpebrarum muscle, combined with one or other of those states, are entertained at the present time, and are ingeniously and plausibly advocated by their several propounders. I question the soundness of these speculations, but admit that there is reasonable probability in that which attributes the disease to occasional faulty muscular action.

To say, that looseness of the skin of the lid allows of inversion of the tarsus, would be to affirm, that, in a healthy eye, the skin is antagonistic to some power acting on the lids,—a statement physiologically erroneous. The skin of the lids is never tense, but always loose, as a natural provision for their unrestrained movements; and this is especially exemplified in the upper lid, where the motions are freer than those of the under. Moreover, it is singularly thin, and apparently devoid of elasticity, or, at most, possesses it in a minimum degree; and were it required to show more than this, I would point to the baggy and even sometimes pendulous state of it in advancing life, co-existent with the perfect integrity of the ocular appendages.

The supposed influence of the palpebral conjunctiva in producing the inversion has been taught for more than two hundred years, and has been particularly urged of late by Mr. Wilde, in a very instructive communication to the *Dublin Medical Journal*, for March, 1844, and since in a pamphlet, for a copy of which I am indebted to the courtesy of the author. But it appears to me, that the morbid changes it may exhibit in these cases are merely the effect of the general irritation of the eye due to the inversion; for in incipient entropium, when the irritation of the cilia is confined to the conjunctiva of the globe, I have not been able to satisfy myself of any condition of the palpebral conjunctiva that may not be seen in a healthy eye. After a time, which varies according to circumstances, when the entire conjunctiva is involved in that general inflammation which is

sure to ensue in the progress of the affection, that on the lids does exhibit various morbid appearances, which, as far as I can make out, differ in no respect from those resulting from inflammation from other causes, and from which the lid does not become curved.

That the unnatural state of the lid may depend on some primary change in the shape of the tarsal cartilage seems most probable, and is that most generally received as the true explanation. To examine into its correctness is a matter of some difficulty, and the only reliable method I can suggest, is to select those cases of entropium that are not complicated with other diseases of the lids, either as a consequence, or what would appear to be usually a precursor, or excitant of the affection, and by which the cartilages may be influenced: for example, those in which there is neither inflammation, nor any of those changes in the lid which arise from inflammation. And it will simplify the inquiry even more to look principally to an inverted lower lid, because that lid offers a greater facility for observation, as the natural direction of its border is outwards and away from the globe; and any change or alteration in its direction can be better appreciated than in the upper, where the margin inclines somewhat inwards. Besides, there is a very marked difference in the size of the cartilages, and which may throw additional light on the inquiry; the lower is about half the breadth of the upper. In the most marked or aggravated stage of entropium in the under lid, the tarsus does not rest against the globe as though it bound it, because of being contracted in any direction; but the lid is so completely turned on itself, that the cilia are hidden, the narrow cartilage is, in fact, rolled up in the lid, and its position is completely reversed. It is dislocated in a manner which I have attempted to show in this diagram. It is evident, from the narrowness of the cartilage, that no curve of it, nor any kind of contraction, could produce those changes in the lid. But, more than this, I have never been able to satisfy myself that the cartilage is ever at all altered or modified; and, if not, it cannot have any degree of influence in producing the inversion.

In entropium of the upper lid, the inverted cartilage rests against the globe, and the convexities of the cilia are then on the cornea, while their extremities are directed outwards, a position that their ends assume from the handkerchief being used in that direction during the frequent calls for its application. In some aggravated cases they lie spread out on the globe of the eye. Now, this difference in the directions of the edges of the lids ought not, I think, to be sought in dissimilar causes, but attributed, I imagine, to the same causes acting on the dissimilar physical constructions of the lids. The cartilage is curved on itself, its breadth not allowing it to be rolled up, like the cartilage of the lower lid.

With an exception or two, the influence of muscular power has been regarded principally in the light of a partial secondary cause, blended with some one of the supposed primary causes that I have examined. And the more general opinion is, that its detrimental action is induced by tegumentary disarrangements, by relaxation, or by swelling of the skin over the upper part of the lid, by which its influence in supporting the muscular fibres of that part is lost, while the remainder of the muscle on which the skin yet acts continues its function, and rolls the edges of the lids inwards. The assertion of the action of the orbicularis depending on the binding of the skin, is thoroughly untenable.

The similarity of all entropium in the direction of curvature, the implication of the whole lid, and the symmetry of the deformity, induced me to attribute the affection to one and the same cause, and I strongly suspected that to be muscular action; for by no other cause did it appear to me that those changes could be produced in the lower lid, when affected with entropium, by which the lid can be so quickly twitched in after remaining in a righted position for a few minutes; but, having some misgiving of the power of that part of the muscle on the edge of the lid, and which is described as the thinnest portion of the orbicularis, to exert such an effect,—for doubtless to that part alone could such action arise,—I made a few dissections, to satisfy myself of its real nature. I found that over the edges of the lids, for about the sixth of an inch, the muscle is thicker, perhaps twice as thick as over the remainder of them; just what would be expected of a sphincter,—the fibres redder, larger, and more compact. In the lower lid, this marginal portion is greater, and the fibres lie irregularly in bundles. This fact seems generally, as far as I can learn, to have been overlooked by modern anatomists, although it was noticed and even figured by the sagacious Albinus. I suspect, that he was the first author in whom originated the name musculus ciliaris, thereby signifying a distinct muscle. Although this term has been retained, it is not generally used in the sense to which Albinus restricted it. To prove what I say, I quote from the late Mr. Dalrymple's "Anatomy of the Human Eye," which has been a standard work for many years:—"The few pale and horizontal fibres which immediately cover the tarsal cartilages, and which are continued to the edge of the palpebral fissure itself, have received the name of musculus ciliaris." Albinus's muscle is only at the edge of the lid.

Just about the time that I was investigating this muscular origin of entropium, one of my colleagues in the Central London Ophthalmic Hospital, showed me that he could, by the influence of the will, invert the edges of both his lower lids, produce the most complete entropium, and conceal his long and numerous cilia. Of course this greatly strengthened my opinion, and I did not hesitate to regard my idea of the cause of entropium as being correct. After that I made some dissections, to ascertain the relation of the tensor tarsi muscle to the orbicularis, and was not a little surprised to find that it has such a connexion with that muscle, that it may justly be considered a part of it—that part which has a bony attachment.

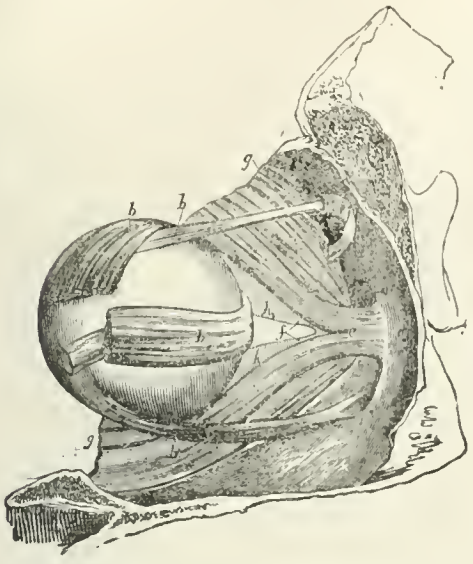
The correct anatomy, and the relations of this supplemental portion of the muscle, have hitherto not been sufficiently understood; but the existence of it was well known to the older and generally more minute anatomists, in proof of which I would merely quote Duvernay, "Œuvres Anatomiques. Paris," who wrote and lectured with great *éclat* in 1761, or nearly a century ago. But it came to be neglected or overlooked, with much of the minute anatomy of the times of Santorini, Morgani, De Graaf, and a host of others, until public attention was again called to its excellence by Rosenmüller.

Dr. Duvernay, in describing the lachrymal sac, and the fibres of the orbicularis muscle connected with it, says, Tome 1st, p. 130, besides these fibres, there is a small muscle within the greater angle which arises from the anterior point of the os planum, and is inserted or attached to the internal curvature of the common tendon of the opposite side of the orbicularis. It is a small muscle which I observed a long time ago. Horner, who has for a great many years claimed the discovery, which, as I have shown, was made and published before he was born, appears to be ignorant of its exact bearings. In his latest writings that I can meet with, apparently the last edition of his work on Anatomy, bearing date 1846, after the principal description of the muscle, which is made to end at the puncta lachrymalia, he adds, "The superior fork, however, has a few of its fibres blended with the orbicularis."

In Arnold's beautiful Tabulæ Anatomicæ Fasciculus duo, the muscle is noticed as a small triangular slip, with the apex towards the corner of the lids, where it is made to terminate.

To speak of it as a distinct muscle, I should say it arises as a thin plane of well-marked muscular fibres of about the fourth of an inch in length, from the vertical ridge on the lachrymal bone, passes forwards and outwards towards the lachrymal sac, and bifurcates in a remarkably distinct manner, the branches proceeding towards the lids, and on their edges become blended with the obicularis muscle. They can be traced to the middle of the lid. In their passage, these branches distribute fibres to the posterior surfaces of the puncta, and some few would seem to surround them. The best manner of tracing it, is carefully to remove the skin from the orbicularis, then to detach the upper and outer walls of the orbit, divide the optic nerve and the

muscles that surround it, and draw the back of the eye outwards and forwards.



Back view of the orbit: the vessels and nerves have been removed, and the eye drawn outwards, to show the origin of the tensor tarsi muscle.
a Globe of the eye.
b b b b Superior oblique, inferior oblique, internal and superior recti.
c Lachrymal sac.
d Muscular origin of tensor tarsi.
e The bifurcation of tensor tarsi, the branches of which give a few fibres to the puncta, and terminate in the substance of the orbicularis.
f The puncta lachrymalia seen in the fibres of the muscle.
g g The orbicularis palpebrarum.
h h Tarsal cartilages, on the anterior surface of which the united tensor tarsi and orbicularis muscles pass.

So great is the variation in the development of this muscle, and also of the musculus ciliaris, that occasionally it is scarcely possible, with the naked eye, to recognise the muscularity of their fibres.

It is not surprising that, as the anatomy of the tensor tarsi had not been ascertained, its physiology was only partially understood, and any pathological state was never conceived. As far as I can ascertain, with the single exception of Dr. Physic, who took the most extended view of its action, and justly supposed that it must exert some influence on the movements of the lids, writers have confined its use to the apparatus for conveying away the tears. In the last edition of Dr. Quain's Anatomy, by Dr. Sharpey, 1848, it is called musculus sacci lachrymalis.

It is as difficult, nay, impossible, to decide, what are the circumstances that bring about such unequal and prejudicial action of the orbicularis, as to account for the production of a squint, or of any other deformity, the result of perverted muscular action, for they occur without the perceptible influence of any cause; and the most that can be said of them is, that sometimes they follow other pathological phenomena of common occurrence, which are then regarded as excitants, and, in the case of entropium, conjunctival inflammation would seem to stand in that relation.

I have founded the treatment on what appears to me to be the pathological interpretation of the affection, and of which the indications are, to overcome the means of inversion by dissecting away the thick marginal portion of the orbicularis, supposing that part of the muscle to be entirely, or nearly all that is at fault, and also to remove as much of the skin of the lid as may be required by its loss to produce such tension as shall overcome and restore to a natural state, whatever unnatural position the other tissues or component parts of the lid may have acquired, from the irregular position into which they have been thrown by the muscle, and which has been made more or less permanent by such changes as inflammation would produce.

Now, as to the manner of operating: let us suppose that the right eye is to be done. An assistant stands behind the patient, and having made the lid tense by drawing it outwards and raising the brow, two incisions are to be made through the skin and muscle, one along the edge of the tarsus close to the cilia, and the second about the quarter of an inch above, and meeting the other at the extremities. The flap thus isolated should be dissected vertically from the one side to the other, and not taken away by horizontal strokes of the knife, or else the muscular portion will not be effectually removed. The wound should be very carefully sponged during the operation. Any arterial jet must be checked by temporary pressure with the finger. I have never found a ligature to be necessary. The exposed surface must be inspected, and, if any muscular fibres have escaped, the forceps and knife must be re-applied. The assistant should not desist until the knife has been laid aside, for the proper retraction of the skin is essential to steady and effectual dissection. Three or four sutures should be used. The cilia might appear to be in danger of being dissected off, but in reality they are not. A part only of the dissection is over them, and, by the loose cellular connexion, the muscle is readily raised from the dense fibro-cellular tissue in which they lie.

The previous observations almost demand a cursory view of the usual methods of operating, and their results; indeed, I think this paper very imperfect without it; yet I fear that its introduction would make my communication too long. I must be satisfied with making the assertion, that there is not any known method of operating for entropium, that can be depended on, except that of cutting off the greater portion of the lid, and which is as bad in principle,—nay, even worse, if the physiological relations of the lid be taken into account,—as to amputate a thigh to cure a popliteal aneurism.

Heretofore, when an operation for entropium has been undertaken with the design of removing any part of the orbiculuris palpebrarum muscle, it has been executed on very different principles, and in a very different manner to that I now advocate, and with very different results. The marginal part of the muscle, the musculus ciliaris, has been untouched, and only a bit of the centre of that on the lid has been snipped out. The only exception I know of is in the practice of Mr. Key. I am astonished that the notice of the operation he performed, and which is in the *Lancet* for 1825, page 235, should have escaped the attention of our writers on ophthalmic surgery. It is very lately that I have been acquainted with it, long after I had matured my own views. I cannot say whether Mr. Key continued to execute it, and what were his ideas on the subject in later years. The report runs thus:—"Mr. Key considered the inverted state of the tarsus to arise from the action of the orbicularis palpebrarum muscle. With that view he determined on laying bare the substance of the lower tarsus, and dissecting off the fibres of the orbicularis. The operation was performed by first turning out the lid, and then making an incision through the skin along the whole length of the lower eyelid, at a few lines distance and below the ciliary ridge; the integuments were carefully elevated by means of dissecting forceps, and the fibres of the orbicularis thus exposed were as carefully removed; there was considerable bleeding from the parts; the portion of skin which had been raised was laid down, and the wound dressed by means of adhesive straps, with a compress applied on the skin. The result is said to be successful. Mr. Tyrrell and Mr. Travers had operated previously, the first by cauterisation, the second by removing a portion of skin without success."

M. Desmarres has not overlooked the influence of the orbicularis in producing the inversion, and he gives a case that he thinks solely due to it; but he does not recognise its general operation, and he significantly indicates how little he appreciates the principle of Mr. Key's execution, and the triumphant issue of the case, by asking, in a commentary on the proceeding, "Is it to the incision of the skin, or the excision of the muscle, that the success is owing?" Spasmodic action of the muscle is spoken of by foreign authors, but with much difference of opinion concerning its frequency in producing entropium. The usual Continental mode of operating on the orbicularis is subcutaneous incision, which seems to have been unsuccessful; that of M. Janson de Lyon is a terrible affair, the cutting out of several vertical portions of skin, including some fibres of the orbicularis. Dr. Mackenzie, in his only notice of operating on the muscle, informs us, that it may be proper, after removing the cutaneous fold, to snip off a few fibres, so as to form a firmer cicatrix, actually fixed to the cartilage; and Mr. Lawrence, a much later author, echoes the same thing, for he writes, "In an incipient case, it may be sufficient to excise a portion of skin; this remedy will, at least,

answer the purpose for a time. To make the operation more effectual, a portion of the orbicularis should be removed also, that a firmer cicatrix may be produced; or the acid may be employed, using it more freely, so that its action may extend deeper, and a solid scar be the result."

A narration of cases, with the various symptoms and terminations of entropium, must be excluded from this paper, which is intended to embrace only general principles.

As trichiasis commonly exists with entropium, and the operation I have advocated bears on the united affections, I shall say a few words relative to it.

With inversion of the upper lid, there is not unfrequently decided trichiasis, and, whether the two are due to the same exciting cause, or the trichiasis have been the original affection, or merely an effect of the inversion, it matters nothing as far as the treatment is concerned; yet it may not be amiss to remark, that, with severe entropium, the edge of the lid can rarely for any length of time escape from being affected by the general inflammation, and that the cilia will the more readily retain any unnatural position in which they may be placed. And I am inclined to regard the trichiasis more frequently as an effect, because it is generally of one form, that of a separation or twisting in of the innermost of the cilia from their fellows, and that without any alteration or degeneration in the individual hairs, and because the removal of the entropium is generally sufficient to clear the globe of them. Although, practically speaking, such a degree of trichiasis matters little, it is important, before operating for the entropium, to ascertain whether there is also trichiasis, and whether the restoration of the lid to its natural position will or will not counteract the maldirection of the cilia. Should it not be sufficient, then more skin must be taken from the lid than would otherwise have been necessary, and a slight degree of eversion of the centre of its edge produced, and which must necessarily have its limit. When it is apparent that such moderate eversion will not suffice, the treatment must depend on the degree of the trichiasis; if it be general, the entropium and it must be attacked by one operation. The cilia must be excised at the same time, that a sufficient extent of the skin of the muscle should be removed. But, when the trichiasis is partial—and, for the most part, it is—the muscle should first be dissected away, and then the irregular cilia removed. When there is doubt about the necessity of removing them, attend to the entropium alone, and observe the result, because it is not always possible before the operation for the entropium has been done, and the lid recovered from it, as well as from any inflammation and swelling that the entropium may have induced, to ascertain with exactness to what extent the trichiasis may be benefited. If, as is commonly the case, a patient applies to be treated for entropium, with many of the cilia broken, and some just about to be restored after having been plucked out, it cannot be known what direction they may assume when growing out; and such cases should be watched.

It can be very seldom that the removal of entropium from the lower lid does not at the same time separate any irregular cilia from contact with the globe, for a single exception only has occurred to me.

55, Grosvenor-street.

EXCISION OF JOINTS.

By G. M. JONES, Esq.,
Surgeon to the Jersey Hospital.

[Concluded from page 437.]

Case 1.—Catherine Anderson, aged 47, unmarried, was admitted into the hospital July 4th, 1851, in consequence of an affection of the right arm and elbow, which altogether incapacitated her from following her usual employment, that of cook. Her appearance is not that of a healthy person, for though by no means emaciated, her complexion is sallow, and her looks are indicative of pain and uneasiness.

For many years has experienced pain down the arm and elbow, for which no advice was taken, and no remedies employed save liniments, as she always regarded the affection as rheumatic. Three years since the pain (which she represents as having always been much more acute during the night than in daytime) increased so much as to induce her to consult a surgeon, and shortly after his attending her an abscess was opened midway down the front part of the humerus; this was a considerable time healing, and has left rather a deep scar. Since that time she has suffered much more than she did before; she also dates the contraction of the elbow from that period. The catamenia have always been irregular.

Present Appearance.—The arm is bent at a right angle; the external condyle of the humerus, when pressed, gives considerable pain, but scarcely so much as is experienced when the olecranon is touched. The joint, which is considerably puffed, particularly at its humeral part, admits of very slight motion; there is considerable thickness and hardness of integument down the back part of the lower half of the arm, considerable heat of surface, and occasionally a throbbing sensation is complained of. Appetite very indifferent; bowels generally constipated; tongue coated; pulse 94, weak.

From the day of admission, to the 24th November, the different means, both local and constitutional, which are recommended in cases of this nature, were tried, but totally without success. The pain had now become so great, and the poor woman's nights were so extremely restless, as to make her most anxious for the removal of the arm. I must candidly avow, that I had misgivings as to whether this were not more a case for amputation than excision. The appearance of the lower end of the humerus impressed me, as well as others, with the belief, that the shaft of the bone participated, to a great extent, in the disease which, without doubt, existed in the joint itself. Fearing this was so, I was led to operate differently to what I had done in Ste. Croix's case. Instead of making my incisions like the letter H, I made them in this form ⊣, which was accomplished by two strokes of the knife; the first commenced half way down the back part of the humerus, was carried in a straight direction till it reached the external condyle, along the side of which and the olecranon it was afterwards directed, and in the same manner along the inner condyle and head of the radius; these parts being dissected, and the joint thus perfectly exposed, the whole of it was seen to be in a miserable state of disease; it was, however, most gratifying to discover, that the shaft of the humerus was entirely sound. There was matter both inside and outside of the joint; the head of the radius was considerably diseased, so that it was absolutely necessary to remove more bone than in Ste. Croix's case, in which, to all appearance, caries existed to a far greater extent. The operation did not occupy much time; the integuments were brought together by eight sutures, and a few adhesive straps, with lint dipped in cold water, completed the dressing. The limb was placed in a triangular splint, and quinine wine and nourishing diet commenced the same day, up to the 28th, not one bad symptom had appeared; on that morning the bowels were acted on for the first time. All the dressings were removed, and it was found, that almost the whole extent of the incisions had united by first intention. From this date to December 13th the dressings were removed every second day, when they became no longer necessary, every part having entirely healed. On the third day after the operation the patient sat up the greater part of the day, and she has since left the hospital for days together. She is now able to raise the whole arm without any assistance, and I make no doubt will shortly bend and straighten it at pleasure.

In this case 2½ inches of bone were removed.

It may perhaps be considered, that I have been tediously minute in entering into the origin, progress, and treatment of these cases. Had they not differed in many essential points, the full detail of one, and the mere mention of the result of the others, might have sufficed for any practical purpose; but, as the constitutions were by no means the same, the causes which laid the foundation of disease, and ultimately led to the resection of the joints, dissimilar, the result of the operation, though satisfactory in all, yet different in each case, I have been induced to note down more than at first sight may appear necessary, and also to make a few remarks which, I trust, may not appear altogether uncalled for.

Perhaps no two cases more dissimilar in essential points than those of Handsford and Le Gros could fall at the same time under treatment. In the former, no decided scrofulous diathesis was observable; her parents are healthy, and none of their offspring have the slightest appearance of struma. Her disease was not the effect of injury, and it would appear, from facts which have lately come to my knowledge, that the primary affection of the knee was nothing more

than one of rheumatism, the result of cold and exposure to wet, which might probably have yielded to rest and judicious treatment, had not the same exciting cause which first produced inflammation acted over and over again. The progress of the disease was so slow, that the constitution became as it were, for some years, habituated to it, so that it was not many months before the operation was resorted to that it had progressed so far as to preclude all hope of cure, or of anchylosis taking place, and, when it was performed, a delay of some weeks, at least, might probably have been allowed, before the life of the patient would have been so endangered as to necessitate the amputation of the limb. Le Gros's case was, in its most important points, different. Born of strumous parents, he was not only predisposed to scrofula, but his glandular system had already been affected by slight causes before he received the blow which eventually led to the destruction of the joint. Always of a delicate and feeble constitution, he was little able to grapple with the general derangement commonly produced by caries of the bone. A more wretched case could not well have presented itself; hectic fever, with its worst concomitants, had literally worn him down to a mere skeleton. The abscess, too, in the thigh, from which issued such an abundant discharge of whey-like fluid, with flakes of coagulated lymph floating on it, and which evidently communicated with the affected articulation, was by no means an encouraging feature in the case. In Handsford's there was much which afforded reasonable hope of a favourable termination. None of the symptoms were sufficiently bad to counterbalance the promising ones, whereas, in Le Gros's, all were of the worst character. The former evinced a sweetness of disposition and moral courage seldom met with, and which must have assisted Nature in the task she was called on to perform; while the latter was pettish and fractious in the extreme, and so irritable, that even a look was sufficient to prostrate him to a degree almost bordering on syncope.

It may be said, and with some show of reason, that this was not a subject in which resection of the joint ought to have been practised. Certainly it was not the case I should have chosen for a *coup d'essai*, and yet it was, in every respect, the kind of case I felt, at the time, anxious to meet with. Sarah Handsford was then progressing favourably, and I considered the success which I flattered myself as likely to follow the operation as perhaps the result of its having been performed before the constitution had materially suffered. I therefore wished, if possible, to prove, by the evidence of facts, that if excision of the knee-joint is in any case a justifiable operation, the cautious rule laid down by many of the most celebrated surgeons, "that only under peculiarly favourable circumstances should the removal of the joint surface be preferred to amputation," admits of being extended in reference to cases where it can, with safety to the life of the patient, and with success also, be performed. There are some who disapprove altogether of this operation, and not a few who are but lukewarm supporters of it. I can well understand the caution recommended by those who advocate the resection of the knee-joint, but am at a loss to comprehend why it should be altogether denounced, as, although some cases are recorded of complete failure, where the limb has proved useless, and even death has resulted, still it should be remembered, that, in the hands of Parks, Crampton, and others, it has been eminently successful.

Mayo, an author of high and well-deserved celebrity, in his "Outlines of Human Pathology," appears, judging from the following paragraph, to denounce all resections of joints, save that of the shoulder. He thus expresses himself:—"Of excision of the articular ends of bones in joint diseases, what I have seen of it leads me to speak with no approbation; I suspect, where it has been performed successfully, it has been performed before the degree of exhaustion which renders an operation decidedly necessary has arrived; where an operation is clearly required, the constitution has generally no longer force enough to support the tedious process of restoration which follows excision, it is better, in my opinion, to wait till all chance of other cure has failed, and then to amputate." I cannot subscribe to these views; and, whoever reads the cases of Ste. Croix and Le Gros, will, I think, consider me justified in stating, that, even where the result of amputation is doubtful, excision may be, as these instances prove, successful.

The cases of Ste. Croix and Anderson are of practical interest, the latter strikingly exemplifying the immense advantage gained by operating while the soft parts are in a state of integrity; while the former proves how correct was the opinion of the elder Moreau, "that the degeneration of the soft parts, depending alone on disease of the joint end, should by no means forbid the operation of excision." I believe that, without being over sanguine, I may be allowed to hope that Anderson's case will, to say the very least, prove quite as successful as Ste. Croix's; and yet I feel persuaded, that a continued delay of three or four weeks would have brought the integuments and muscles of the elbow of the former into as wretched a state of disease as existed in those of the latter. This case, then, proves how much is gained by an early removal of the diseased bone. Anderson's arm was perfectly healed in nineteen days,—Ste. Croix's took six months and upwards before this desirable end was attained; the arm required daily dressing for more than half a year, while the other within a month required none whatever. Had I waited "till all chance of other cure had failed," I might with reason have expected to find my patient having "to support the tedious process of restoration which Ste. Croix had, on this very account, to contend with; or, if in his case I had followed the plan recommended and adopted—amputation, I should not, as at present, have the satisfaction of finding that my patient is able, from the saving his arm, to maintain a wife and large family by resuming his former employment.

In a paper read by Mr. Gay,(a) a short time since, before the Medical Society of London, that gentleman strongly advocates free and deep incisions along each side of a diseased joint, as the best method of effecting a cure, and, at the same time, preserving the limb. He regards resection as "not only a useless, but an unphilosophical mode of treatment for diseased joints." Far be it from me to oppose the opinion of one whose opportunities of judging of the advantages of one method of treatment over another must necessarily be much greater than my own; but I believe all those members of the Profession who have seen the portions of diseased joints on which I have operated, will agree with me, that it would have been a much more "unphilosophical mode of treatment," as well as a "useless" expenditure of time, to have endeavoured to cure, by means of incisions, cases in which, not only the cartilaginous surfaces, but the structure of the bones themselves were implicated. So far am I, however, from condemning the practice of free and deep incisions, that I have already tried it in several cases, one of which is recent, the patient, Jane Burton, being still in hospital. The disease was of at least twelve years' standing, and suspecting, in consequence of a constant discharge of ill-conditioned pus about the diseased joint, that the upper part of the femur was in some degree involved, I made an incision by which the bone was laid perfectly bare from just below the trochanter downwards to the extent of at least four inches. The wound thus made was filled with pledgets of lint, and gradually healed by granulation. Whether the cure, which appears perfect at present, will prove a lasting one, must be left for time to decide.

Two reasons have been urged against the propriety of excising joints; one, that this operation places the life of the patient in far greater jeopardy than does amputation; the other, that even when successful as far as concerns life, it is more than problematical whether the limb thus saved will be of any use. These reasons, at one time considered powerful, not to say conclusive, have very much lost their weight. There are now many who believe, "the most discreditable operation in surgery is an amputation,"(b) and that "a determination for or against amputation is really a determination for or against the patient's existence."(c) In early life, where a man's surgical knowledge has advanced but little beyond theory, the deductions drawn from the experience of others must of necessity be the rules for his line of practice; but when, by practice, he has been enabled to test the truth or fallacy of his guides, he then chooses for himself that plan which appears to his judgment to promise the surest present relief, together with the smallest amount of future inconvenience to the patient. Not being aware if, in the London hospitals, a yearly account is published of the recoveries and deaths after capital operations, I am unable to ascertain the per centage of the successful

(a) Vide *Lancet*, Nov. 22, 1851.
(b) Skey's "Operative Surgery."
(c) Pott's "Surgery."

cases over the unsuccessful. From a statement given some time since, I infer that a regular return is made at certain periods from all the principal hospitals in Paris. The statement to which I allude embraces a period of five years, from 1836 to 1840, and contains the following list of amputations, with their results:—

	Cases.	Deaths.	Recoveries.
Thigh	201	126	75
Leg	192	106	66
Arm	91	41	50
	484	273	211

Showing, that out of 484 amputations, 64—over one-half of the cases—died.

It being only during this year that I have attempted the resection of diseased joints, my experience may perhaps be considered as insufficient to warrant my offering satisfactory evidence for or against this operation. The result, however, of this experience, limited as I admit it to be, has fully impressed on me, that excision is not generally attended with greater danger to life than is amputation. This is evidently proved by the result of the capital operations above alluded to (though at the same time I feel persuaded, that the great per centage of fatal cases in the Parisian Hospitals are not altogether data to go by). The first objection, therefore, falls to the ground, and the termination of the only four cases which have occurred at this Hospital,(a) so far answers the second, and in a great measure may establish as a fact, that limbs can be saved which formerly would have been removed, as well as that disease of the bone must have progressed to a very great extent not to admit of removal without implicating other parts; but in advocating, as I must certainly do, the excision of joints, and while wishing others to follow a practice which I cannot sufficiently regret not having pursued earlier, I must impress on their minds, that the saving a valuable limb requires a sacrifice of time and an amount of trouble on the part of the surgeon much greater than is needed in ordinary amputations. It will not do to imagine, that when the instruments are laid aside almost all is accomplished, or that that part which requires a steady hand and presence of mind, together with a knowledge of the parts to be operated on, embraces the whole of the task which devolves on us. The operation itself is but the mechanical portion which these requisites can in a great measure accomplish, and which brings many witnesses round us; but it is where this has been done that our chief employment may be said to commence in the after-treatment, that practical part where we generally find ourselves deserted, and on which principally rests the success of our first endeavour, and the future well-being of our patient. There are cases in which the surgeon ought for a considerable time to act, as it were, the part of head-nurse, so that every change of symptom might at once be attended to. This can only be effected by constant watching. We may have attendants on whom we can place a certain degree of reliance, but it is far better to trust to our own observation; many symptoms and appearances which to others may seem too insignificant to be reported, may in reality be the sources from which important inferences are to be derived; and I feel convinced, that, if this were acted on as a more general rule, the final result of many operations would be as much noticed as is the *éclât* with which they have been performed. For many years past I have almost invariably pursued a stimulating plan after capital operations, and, I believe without a single exception, after those which have been performed in consequence of chronic affections; and in no one instance have I had reason to regret this course. The treatment recommended by authorities is very contradictory, some advocating an antiphlogistic plan, while others administer bark and wine. The former method is, I believe, still very much, if not altogether, adopted in France and other parts of the Continent; at no period, moreover, has it been so generally pursued in this country, and, as far as I have had opportunities of ascertaining, is by no means the general practice of the present day. I have every reason to believe that an eminent surgeon, (Mr. Skey, of St. Bartholomew's Hospital, to whom I owe a deeper debt of gratitude than words of mine can express,) ranks among the advocates of the latter plan, for, in a case of diseased os calcis, in which his high surgical attainments, guided by a most correct diagnosis, preserved a limb which was all but condemned to amputation, recommended stimulants immediately after the operation, and with signal success. It is to be lamented that others do not follow his footsteps, not only in adopting this plan of treatment, but also in reprobating the evacuant practice, the administering aperients immediately after operations—a practice which, unfortunately, is still persevered in by many, and which, I feel persuaded, often defeats Nature in the object she is striving to perform. To lay down anything like positive rules for after-treatment, would be quite as faulty as the invariably abiding by one plan. The surgeons of the old school frequently cling to a certain treatment, and to remedies they have been for years in the habit of adopting, and, regarding all changes or discoveries as ephemeral, treat them with contempt. Times are, however, happily changing fast; and, instead of placing implicit faith on authorities, men judge in a great measure for themselves, and guide their practice, not from preconceived opinions, but from results.

I am inclined to believe that, when fresh from the schools of medicine and surgery, we are all liable to an error which a little experience, gained but too often at the expense of our patients, soon corrects. The rapid pulse, the furred and coated tongue, with heat of surface, are regarded as unequivocal signs of inflammation; and our treatment is in accordance with our diagnosis; both are at fault, and either the patient sinks, or Nature, in whose powers we do not always sufficiently rely, triumphs over our treatment; but how lengthened and how slow becomes the recovery!

It will be seen, that the stimulating plan was most rigorously followed in the cases I have given the history of; it was commenced immediately after each operation, and steadily pursued for a considerable time. It is not in these cases only that a similar course has been followed; and I cannot otherwise than attribute the great success which has attended the many amputations I have performed, mainly, if not entirely, to its adoption.(a) The dread of producing too great or too sudden a reaction often leads to a mode of treatment which, in my humble judgment, is not only prejudicial to the patient, but opposed to anything like sound reasoning. It is a principle in English surgery to obtain union by the first intention, whenever it is possible to do so; and I know of no means more likely to gain this end than the rousing, if I may so express myself, of the general system. What is the state in which we usually find our patients when they are placed on the operating table? Most of them are emaciated to mere skeletons, the consequence of hectic fever, and the different drains, colliquative sweats, diarrhœa, etc., occasioned, it is true, by a local affection, but at the same time one which influences, in a greater or less degree, every part of the sufferer's frame. Why, then, the dread entertained by many of producing too great a reaction in subjects of this kind? The reasonable cause for

(a) These are the only operations of excision I have performed in the hospital. I have however, another to record, which proved unsuccessful. A lady came from the country, to be under my care, having for nine years laboured under an affection of the knee, of which the general appearance evidently showed disease of long standing. The operation of resection was performed on the 4th September, and thus far with perfect success, every portion of diseased bone (including femur, tibia, and patella, the two former being in a state of caries, and the latter considerably disorganised) was removed. The first dressing was most gratifying,—almost the whole of the wounds had united by first intention, so that every hope was entertained of a speedy recovery. On the eighth day diarrhœa came on, followed almost immediately by dysentery. No treatment pursued was able to check it, and the patient sank on the 17th. There was a rather remarkable feature in this case,—the dysenteric symptoms did not in any way interfere with the healing process in the knee, and a few hours before death, when the limb was dressed, everything connected with the operation presented a most healthy appearance. It would, perhaps, be too much to assert, that the operation was not the cause of death; it is, however, certain, that almost immediately after this operation, dysentery broke out in the immediate neighbourhood; and that the mortality in this town, principally from this affection, was greater than it had been at any other given period during the year; and though, on the one hand, I am willing to admit, that had the operation not been performed, an attack of this prevailing disease might not have caused the death of my patient, still, on the other, I cannot but believe, that had the epidemic not existed, the operation would have proved eminently successful. This opinion may be wrong, and, for the sake of argument, I will suppose that it is so; still, four successful operations out of five, or 80 per cent., cannot otherwise than prove that excision of a joint is by no means more dangerous to life than is an ordinary amputation.

(a) It is not in cases of amputation and excision only that I consider the stimulating plan as offering far greater advantages than the antiphlogistic. Some time since, in a case of lithotomy, where a calculus almost the size of a pullet's egg was extracted, I at once commenced this treatment. My patient was cured and able to leave the hospital on the 19th day; and lately, in one of very large diffused popliteal aneurism, in which the femoral artery was tied, the same treatment was pursued with perfect success; though it had been a matter of deliberation before the operation whether amputation were not the more justifiable course.

fear is, that our first dressing will prove that the powers of the system have been too weak, and that no adhesive inflammation has taken place; and consequently the tedious and wasting process of healing by suppuration is the reward obtained by our milk-and-water treatment. No man will for a moment suppose it to be in what I have termed the mechanical part of surgery that the Parisian operators fail. Few men are to be found who operate as Dupuytren did; and yet it is probable, that in the Hôtel Dieu the number of his unsuccessful cases equalled those of others whose operations were performed in a much less masterly style; but, by all, the after-treatment was conducted on the same principle; and the best operations of one of the first of French surgeons but too often proved as unfortunate in their results as those performed by men in every way his inferior.(a)

The wish to advocate, as far as my humble testimony may do so, a mode of practice so much approved by Syme, of Edinburgh, as well as by many eminent surgeons of London and Dublin, together with these lengthened remarks, may appear like egotism, but it gives me sincere gratification to have this opportunity of adding that, during all the operations above mentioned, I have received the most liberal and disinterested support from many of those among my Professional brethren whose esteem I value, and on whose opinion I place reliance; and much of the success which has attended my cases of excision may be attributed to the unfailing kindness and attention with which two, in particular—Drs. Brohier and Blood—have, regardless of time or trouble, assisted in watching the progress of the patients. To both those gentlemen I feel deeply indebted, not for this only, but also for many valuable suggestions; so that, if any merit be due to me for being the first to introduce this mode of practice into the island, it must, in common justice, be shared by them.

St. Heliers, 17, Old-street.

THE LONDON PRACTICE OF MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

By J. L. MILTON, Esq.

DISEASE OF THE LARYNX—TRACHEOTOMY—NECROSIS OF THE CRICOID CARTILAGE, AND ABSCESS BETWEEN THE LARYNX AND ŒSOPHAGUS OPENING INTO THE ŒSOPHAGUS.

C. W., a widow, aged 36, under the care of Dr. Peacock, leading an irregular life, was admitted into St. Thomas's Hospital on the 2nd of March, 1852. She stated that she had a venereal affection about eighteen months before, and that she had suffered since that time from sore throat, with hoarseness, difficulty of breathing, cough, and expectoration. She had been an out-patient, under Dr. Peacock, for three weeks before her admission, and, while under treatment for the secondary laryngeal affection, was taken much worse. When admitted she laboured under considerable febrile disturbance, with pain in the side, and other symptoms of subacute pleuro pneumonia of the left lung. This attack was subdued by leeches, blisters, salines, etc., and she was, to a considerable extent, recovered, when, on the 13th, she was found to have taken fresh cold, and the laryngeal symptoms became much aggravated; the breathing was rapid and difficult; no appearance of inflammation could be detected on examining the throat; and, as the mouth was freely affected with mercury, a blister was applied to the nape of the neck, and the dose of antimony which she was previously taking was increased. On the 16th, the symptoms had become very urgent; she was much prostrated; her face was sunken but not livid; the pulse quick and very feeble; the respiration was attended with a loud stridulous sound, and she complained of a constant sense of suffocation. During the previous night she had had several paroxysms of extreme difficulty of breathing, during which she felt as if on the point of suffocation. On consultation with Dr. Barker, it was decided by Dr. Peacock to have recourse to tracheotomy without delay, and the operation was performed by Mr. Le Gros Clarke, at three o'clock in the afternoon. Mr. Clarke, after exposing the cartilages of the trachea, endeavoured at first to introduce a trocar and canula, but, from the extreme mobility of the larynx and the constant coughing, without success; an ordinary trachea-tube was, therefore, substituted, and introduced into an opening made into the trachea; a large quantity of muco-purulent fluid was evacuated; the difficulty of breathing, in a short time, became less; the pulse sensibly stronger, and the expression of countenance improved. After the operation she had occasional severe fits of coughing, with increased difficulty of breathing, followed by the evacuation of much muco-purulent matter; but, upon the whole, she passed a good night, and slept towards morning for two hours continuously. On the 17th she was much relieved; the expression of countenance was more natural; the respirations not much accelerated, equal, and free; the tongue moist, but covered with a slight white fur; the pulse 92, and stronger; the lips and face were of a good colour, and she intimated that she felt much better. She was directed to take a mixture containing the sesquicarbonate of ammonia, compound tincture of camphor, ipecacuanha wine and senega, at intervals of three hours, and to have wine, arrow-root, and beef-tea frequently. For the several following days, she continued to improve; her breathing was generally easy, but was aggravated at intervals when the tube became obstructed by the secretion, but was relieved after the cleansing or removal. The secretion, however, gradually decreased in quantity, and the cough became less troublesome, but the obstruction in the larynx did not give way, and the closure of the orifice of the tube, for a very short period, induced a return of the difficult and stridulous respiration. At first, the wound in the neck being deep, the tube lying at its base very readily became obstructed, and was not easily removed or cleansed. Subsequently, however, a larger tube, resting on the integument, was introduced, and from this, together with the less amount of secretion, she was able to breathe with sufficient freedom. She, however, took very little nutriment, and could only be got to take small quantities of beef-tea and jelly, and was chiefly supported by stimulants. Her strength gradually declined; the pulse became quick and feeble, the tongue furred and somewhat dry, and there was occasional diarrhœa; the wound secreted very freely, and became sloughy. On the 8th of April, the tube was removed, and she breathed freely through the opening in the trachea. She died exhausted on the 11th.

Post-mortem Examination.—Body much emaciated; at the anterior and lower part of the neck, immediately above the sternum, there was an oval, funnel-shaped opening, about an inch and a half in length, which communicated by an aperture a quarter of an inch in diameter with the trachea. The sides of the wound were red and granular, and the larynx presented evidences of considerable old disease. The epiglottis was contracted and irregular above, and the mucous membrane covering its surface and the arytænoid cartilages, was thickened and œdematous. Opposite the cricoid cartilage there were the remains of several partially healed ulcers, and in the centre of one of them there was a minute aperture, only capable of giving passage to a bristle, which communicated with a small cavity situated behind the larynx. The trachea, larynx, and bronchial tubes, to their smallest ramifications, were highly congested, and loaded with thin mucus, containing numerous opaque flakes. The small cavity, before referred to, was situated between the larynx and œsophagus, and occupied chiefly the position of the posterior part of the cricoid cartilage, and was filled with flaky pus, containing several small and rough fragments of bone, which were all that remained of the posterior and larger part of the cricoid cartilage. In addition to the minute aperture by which this cavity communicated with the larynx, there was a second oval opening about half an inch in its largest diameter, by which it opened into the œsophagus. The abscess was separated from the cavities of the larynx and œsophagus only by their mucous lining, and must have produced obstruction of both those cavities, though more especially of the larynx.

The pleura covering the anterior portion of the right lung was rendered rough and opaque, by a thin layer of tolerably recent fibrin, and at the posterior part there were adherent bands. The right lung was completely solid everywhere, and was somewhat smaller than usual. On section it had a pale greyish appearance, much resembling that of the third stage of pneumonia; but the lung was firm, not breaking down except on firm pressure. It yielded a considerable quantity of fluid, which was for the most part thin and serous, excepting where the tissue was broken down, in which case the fluid which exuded seemed to consist of a mixture of serum and pus. The left lung was congested throughout; the lower half of the upper lobe was solid, and the consolidated portion contained more blood than that of the opposite side. The os uteri presented an irregular ulcer on its right side, which was well-defined, deeper than a simple excoriation, and granular on the surface. The other organs of the body were healthy.

(a) It must not be supposed, that I make these observations without authority. In the "Archives Chirurgicales," M. Malgaigne, a metropolitan surgeon, who derived his information from official reports, attributes the mortality which occurs in the Parisian hospitals to "neglect of after treatment." He does not, it is true, say anything for or against the dietetic treatment, but his remarks on the after treatment speak volumes.

LIST OF SCIENTIFIC MEETINGS FOR THE WEEK.

This Evening,	May 22.	ROYAL INSTITUTION. *Subject*:—Prof. FARADAY, "On Points Connected with the Non-Metallic Elements." Three o'Clock.
——	——	MEDICAL SOCIETY OF LONDON.—*Subject*:—Dr. SIBSON, F.R.S., "On the Use of the Chest-Measurer in the Diagnosis of Diseases of the Chest." Eight o'Clock.
Monday,	May 24.	ROYAL INSTITUTION. *Subject*:—J. CONOLLY, M.D., "On Insanity." Four o'Clock.
Tuesday,	May 25.	ROYAL INSTITUTION. *Subject*: — E. LANKESTER, M.D., "On the Physiology of Plants." Three o'Clock.
——	——	ROYAL MEDICAL AND CHIRURGICAL SOCIETY. Half-past Eight o'Clock.
Wednesday,	May 26.	ROYAL INSTITUTION. *Subject*:—J. CONOLLY, M.D., "On Insanity." Four o'Clock.
——	——	HUNTERIAN SOCIETY. Eight o'Clock.
Thursday,	May 27.	ROYAL INSTITUTION. *Subject*: — R. WESTMACOTT, Esq., R.A., "On the History and Practice of Sculpture." Three o'Clock.
Friday,	May 28.	ROYAL INSTITUTION. *Subject*: —Dr. PERCY, "On the Modes of Extracting Gold from its Ores." Half-past Eight o'Clock.
Saturday,	May 29.	ROYAL INSTITUTION *Subject*:—Prof. FARADAY, "On Points connected with the Non-Metallic Elements." Three o'Clock.
——	——	MEDICAL SOCIETY OF LONDON.—*Subject*:—Dr. ROSE CORMACK, "On the Medicinal Uses and Therapeutic Relation of Mercury, Iron, and Arsenic." Eight o'Clock.

Medical Times & Gazette.

SATURDAY, MAY 22.

UNPAID MEDICAL OFFICERS.

WE desire to direct the attention of our readers to the following Advertisement, emanating from the Committee of the Royal Maternity Charity. It appeared in our columns on the 24th ult., and want of room alone has prevented an earlier notice:—

"In consequence of the resignation of one of the Physicians of this Charity, a vacancy has occurred. The division to be filled up is south of the Thames, extending from Nine-elms to the Commercial-docks, and from London-bridge to Camberwell-green. Candidates for the appointment (*which is honorary*) are required to be Fellows or Licentiates of the Royal College of Physicians of London; and the Physician appointed must reside in the above-named division. Testimonials to be forwarded," etc. etc.

We can scarcely trust ourselves to comment on this announcement. The Directors of a rich and extensive Charity publicly solicit the *gratuitous* services of some educated Physician, to superintend the patients of their Institution, and to expose himself to be called at all hours of the night and day to the most urgent cases that occur in the whole range of medicine and surgery, throughout a district extending over an area of, as nearly as possible, *twelve square miles!* FROM NINE-ELMS TO THE COMMERCIAL-DOCKS, AND FROM LONDON-BRIDGE TO CAMBERWELL-GREEN!! So runs the Advertisement; but in the official Report of the Charity, the boundary is stated to extend "three miles from St. Paul's;" which would enlarge the area to *half a mile beyond Nine-elms, and half a mile beyond Camberwell-green.* The ground specified in the advertisement measures four miles in a straight line east and west; two miles and a quarter in a straight line north and south; two miles and one-third in a line drawn south south-west from Waterlooo-bridge to the boundary at Camberwell; and three miles and a quarter in one drawn south-east from the Commercial-docks to the same spot. Besides the densely-populated districts close to the bridges, on the Surrey side of the river, the area embraces the whole of Kennington, Newington, Walworth, Bermondsey, Rotherhithe, Peckham New Town, and a part of the parishes of Deptford and Camberwell, and extends some distance along the Clapham and Brixton roads.

Well, indeed, may it be said, in regard to public medical appointments, that Boards and Committees are daily guilty of acts which, as individuals, they would be ashamed to practise. Well may this Advertisement raise the ire of the Profession. It is generally conceded, that there is no department of medical practice so arduous, toilsome, and harassing, so destructive to health and to comfort, as the obstetric. The difficult and dangerous cases which occur in this branch of the Profession require consummate skill and judgment, as well as instantaneous attention; and yet we see a body of men who desire that educated gentlemen should give up their time and talents, spend their money, and damage their health, for the very equivocal advantages tha would result from taking the medical charge of the patients of a Charity whose affairs are conducted by a Committee so liberal and generous as this has proved itself to be. And these gentlemen will not be contented with anything but a first-rate article for the valuable equivalent they offer, of serving them gratuitously. Candidates must be Fellows or Licentiates of the Royal College of Physicians, forsooth! and they are expected to send in testimonials of their fitness, and bow low, no doubt, before the great men whose sense of what is due to the Medical Profession has prompted them to issue such an unworthy as well as impolitic appeal.

Were the Royal Maternity a newly-organised charity,—were it struggling with the difficulties usually attendant on recent establishment,—with funds inadequate to supply its wants, some excuse might be found for such a notification on the part of the Directors. Then the Profession, with that humanity which has become an actual proverb, would no doubt respond with alacrity to the call. But, considering that it has been in existence ninety-five years,—that it is in possession of a yearly income of nearly eleven hundred pounds in funded property,—and that, from its foundation, the Physicians have always received some remuneration for their time and trouble, it is a great deal too bad, that an attempt should now be made to wring, from the members of our Profession, valuable assistance, rendered with great labour and at a great sacrifice, FOR NOTHING—and this, too, at a time when the feeling of medical men in general is so much alive to the injustice of requiring them to work without remuneration; and when the sentiments expressed in the temperate and admirable protest of the Assistant-Physicians and Surgeons of the London Hospital, which we published in our Journal of the 5th instant, have met with such a lively echo in the breast of every member of the Profession. We call on our brethren to scout the proceedings of the Directors of the Royal Maternity Charity, and to show a proper indignation at the degradation to which it is sought to expose them. We feel satisfied, that no physician can be found who will so far forget what is due to the Profession and to himself as to accept such an office upon such terms.

Independently of the injustice that the Profession would suffer, should the intended plan of the Committee be carried out, the subscribers to the Charity would have good reason to complain. Money has been largely contributed, under the belief and expectation, that the system in force at the time the contributions were made would continue to prevail so long as circumstances permitted. One part of that system was, that such payment should be rendered to the Physicians

for their services as might induce men of skill and experience to devote a part of their time to the interests of the Charity. We ourselves know of Governors who never would have contributed a farthing towards the funds of the Charity, if they had imagined that the patients would at any time be left to the care of an unpaid medical staff, with all the disadvantages that must accrue in such a Charity as this from an arrangement of that description.

It is idle to suppose, that Drs. Sims, Squire, Dennison, Davis, the Ramsbothams, and Sir Richard Croft would have devoted themselves for so many years to serve this Charity without some pecuniary remuneration, were it only sufficient to pay coach-hire to the many cases to which they used to be called. Under their superintendence, indeed, it grew up to be the largest institution of the kind in Europe, considerably more than four hundred thousand women having been gratuitously delivered through its instrumentality. We shall see what it will become under the altered system which it is now proposed to adopt.

THE CHILDREN'S HOSPITAL.

Out of every three children born in the Metropolis, one dies before it reaches the age of 10 years. Such is the sad tale told by the Report of the Registrar-General. Can there be a more forcible appeal made to the public on behalf of this excellent little hospital than this naked, startling fact? Year by year, this huge town has been crowding and squeezing, growing wider and wider, and higher and higher, shutting out the light and the air, without which, children, like flowers, pine and die. Yet, with all these direct attacks upon feeble young life, there has not been, until the present year, a single hospital in the Metropolis devoted to the diseases of children, which must seem strange indeed to those who have travelled, and know that no large Continental town is without one. The general hospitals, it is true, receive children now and then, but to a very limited extent; and, indeed, we do not think it is desirable to mix the very young with adults. There is to us no more depressing sight than to see a very young child in a ward without companions or amusement, and forced to maintain an unnatural stillness. Group children, and nothing but children, together, and the scene is immediately changed, and the most powerful of all stimulants to a drooping frame—amusement and happiness—are supplied.

We paid a visit the other day to the Children's Hospital in Great Ormond-street—a by-gone neighbourhood, whose great houses seem left as landmarks to show the ebbing of the great western tide of fashion. The solemn old mansion, with its noble rooms and splendid oaken staircase, once alive with stiff petticoats of the time of Queen Anne, after being deserted for years, is again the scene of active life. Our ideas of an hospital receive a pleasant shock upon entering a spacious suit of drawing-room apartments, the walls decorated with painted flowers and figured groups, and the mantel-pieces of elaborately carved marble. Around these apartments, the beds of the little sufferers are ranged, and in the centre of the largest room is an ample table—when we saw it, covered with toys. A little party of convalescents were grouped around it, merry as grigs. Toys, there can be no doubt, form the best and most active medicine of the establishment. We saw a large red horse and a Noah's ark, doing more good than countless pills or draughts, if we might judge from the bright eyes of the children. Our suspicions that this was the case, were completely confirmed upon a visit to the dispensary of the establishment, which could well go into an ordinary-sized sea medicine-chest,—not that the remedies were homœopathic in the least. Our old friends pulv. ipecac., hydrarg. c. cretâ, and vin. ant. tart., smiled at us from shiny bottles, in a most orthodox manner; but it was evident, from the smallness of their capacity, that the call upon them was not very extensive. The success of the treatment in this hospital—and we believe it has been very successful—depends upon judicious medical superintendence, good light and ventilation, and fun and amusement. A better site, in the midst of a very populous district, than the one chosen could not have been found. There is scarcely a wider thoroughfare than Great Ormond-street to be met with in town, and the gardens behind are of very large extent; indeed, seeing this open space in the full flush of spring, as we did, we could not help being struck with the country-like aspect of the verdant and wooded scene. The pleasure-ground of the hospital is now being laid down with gravel, and fitted up with numerous gymnastic arrangements, suitable for the amusement and exercise of very young children; this will be a very powerful auxiliary to the general treatment of the hospital.

Air and light, it cannot be too much insisted on, are two of the main elements of health in childhood. We even think, that a large glass conservatory or covered space, such as every hospital ought to have, should have been the first thing erected in these grounds. Into such an apartment the convalescent children might be turned, in all weathers, with as *little* clothing on as possible; for nothing, we are convinced, is so conducive to health, as a free contact of the surface of the body with light and air. At present there are only twenty beds in this establishment, of which at least two-thirds are medical. Fevers are banished to the upper part of the house, and no communication is allowed between the ward appropriated to them, and those below. Even visiters who have entered it are tabooed, and are not allowed to go into the other apartments. By means of this strict quarantine, all fear of contagion—the only one which can be urged against children's hospitals—is, it is believed, avoided. The house is capable of holding fifty patients; this number of beds will soon, we hope, be made up.

Her Majesty, we perceive, has graciously become the Patroness of the establishment, and made a donation of 100 guineas; other subscriptions are fast flowing in, and sympathy on behalf of poor sick children is so universal, that we trust speedily to see this hospital become rich. The intention is to make 100 beds the full complement: this accomplished, the hospital will become *the school* for the study of the diseases of children. At the present moment the medical student looks in vain for any field in which to study this important branch of medicine. It is very common indeed to hear the remark, "I know nothing of the diseases of children;" and this from young men whose practice will mainly lie in attending to their ailments. On the behalf of the progress of medical knowledge, then, we hail the successful establishment of this hospital; at the same time we wish to urge upon the Committee that, when the proper time comes, its doors shall be thrown open to medical students *free of expense*.

We have urged to the utmost of our power, that it is unfair and unjust towards the student to rob our great hospitals of special diseases which they pay to study, and then to demand fresh fees of them at the smaller hospitals. The Children's Hospital is not open to the great and grave objections which we have shown to exist against many special hospitals; it is only special as regards age; our re-

marks respecting them will not, therefore, apply to it. We think, however, that the design of the Institution would not only be eminently promoted, but that it would be wise and graceful of the Committee to set the example of acting liberally by those who wish to make the diseases of children their study, and of showing to the student that he is not an animal the mere use of which is to give out fees,—an opinion which his present treatment is but too apt to engender.

THE GOLD DIGGINGS.

It were bold to pretend to a prescience which others have disclaimed; yet it does not require a prophet to foretell some of the changes which the "gold-diggings" will effect in the Medical Profession. There is no longer a doubt, but that the precious metal may be dug from the Australian soil in boundless quantities, by any one able-bodied, in good health, and not above being his own servant. Of course, we do not apprehend, that four men will again dig 40,000*l.* worth of gold-dust in six weeks; nor, perhaps, can all labourers make 1,500*l.* a-year. But such things have been, and may again occur; and we lately heard from a member of the Profession, who had visited the diggings, confirmation of that with which the daily papers teem.

Civilization is a very great luxury, and worth buying at a very heavy price; but, unhappily, there are many without the means of purchasing admission within the pale of its advantages, or of maintaining their position there when once entered. Who would willingly be surgeon to an emigrant ship, at 2*l.* to 3*l.* a month: or accept the post of "assistant," for a remuneration which a butler would decline, when his time may be more profitably employed elsewhere? We apprehend, and indeed know, that many of those whose ties to the mother country are not of the firmest character, will, instead of undertaking these ill-paid and unsatisfactory offices, join together in small parties to seek a brighter fortune in a more prolific land. In many a Society, and in many a School of Medicine, mutterings of such half-formed plans are already heard. In this country we may therefore expect, that medical knowledge will rise in value, as there will be a smaller supply in the market: while, if the price offered for it be non-remunerative, the possessors will turn their capital to some better account. We are told, that some labourers at the diggings offered a gentleman fifteen shillings a-day to become their cook: what would a man in suffering pay to him who could afford him relief?

We fancy, that the gold discoveries will thus be beneficial to the Medical Schools. All who leave their country with a knowledge of medicine, to trust in a half-organised society to their own resources, will possess very great advantages. A little knowledge, dangerous as it may be, is certainly better than complete ignorance; and hence a year or two passed in study at a large hospital may be regarded as a very good preparatory step to the careful emigrant. It must not, however, be misunderstood, that slight medical knowledge will supersede the necessity of manual labour; on the contrary, he who seeks to build up a fortune in the wild Australian regions must be able-bodied, persevering, and young; he must go out to dig, and to perform such services as labourers at home perform.

What changes may ensue in the next five years! That they will be beneficial we doubt not; but their exact bearings upon the present state of things is a point yet to be determined. The difficulties which have for years beset the path of the medical practitioner in this country have driven men to courses, for the sake of a living, which all sensible persons regret. Homœopathy, hydropathy, mesmerism, etc., have each had their votaries; but now we earnestly trust, that the same energy expended in propping disreputable systems will find a more healthful and more creditable vent in the fields of honest industry.

REVIEWS.

Homœopathy and the Homœopaths. By J. Stevenson Bushnan, M.D., Fellow of the Royal College of Physicians of Edinburgh; Physician to the Metropolitan Free Hospital. Pp. 214. London: Churchill. 1852.

Homœopathy Unveiled, etc. By W. P. Brodribb, M.R.C.S. Eng., and Member of the Court of Examiners of the Society of Apothecaries. Second Edition. Pp. 15. London: Highley. 1852.

Dr. Bushnan's mission seems to be to commit murderous assaults on quacks and schismatics. Some time ago, he pilloried Mr. Atkinson and Miss Martineau; and now he has fearlessly attacked the homœopaths. He has got them in a cleft stick, and pinched them pretty severely. Dr. Bushnan has poured Hahnemann's Organon into his crucible, and the boasted precious metal turns out to be merely German silver.

But let us allow Dr. Bushnan to speak for himself:—

"I frequently receive letters," says he, in his Preface, "to the following effect:—

"'I am a country practitioner; I buy few books, and the only journal I see is the *Medical Times and Gazette*. On the other hand, I am often teased by questions about homœopathy, and am called upon to explain or to refute its doctrines. In the *Medical Times and Gazette* I find little beyond generalities. Will you then tell me where I may procure a brief account of Hahnemann's theories, and a succinct refutation of them?'

"The only work on the subject with which I am acquainted is Dr. A. Wood's 'Homœopathy Unmasked;' but as it, however excellent, does not exactly supply what I consider to be, at the present moment, much wanted, I venture to offer the following pages to my professional brethren, in the hope that they may find in them what I believe they require."—(Preface.)

This intention has been well executed, and in no work with which we are acquainted, has Hahnemann been done such perfect justice to. Dr. Bushnan has shown how all the truth of his system was taken from the recognised knowledge of the Profession, while everything that was original to himself is in the last degree absurd. Nay, it is very remarkable, that Hahnemann's own arguments are so ridiculous to an unprejudiced mind, that they almost always contain their own refutation.

Dr. Bushnan occupies forty pages with an exact analysis of Hahnemann's principal work, the "Organon." The aphorisms contained in that book are here given in eighty-four propositions, in a condensed form; and, although we have not compared the analysis with the "Organon," we have reason to believe that it is very accurate. Then, having got the facts before him, Dr. Bushnan proceeds to discuss each proposition. He shows how many of them are the common recognised truths of Medical Science, and how, when Hahnemann ceased to be a plagiarist, he ceased to be true. The refutation is done with great skill; and, without expecting too much from any appeal to the reason of homœopaths, we do really think that they must vote Hahnemann to be old-fashioned, and set up a modern prophet instead of him. We shall see Hendersonians or Dudgeonites yet arising, we are quite sure.

We cannot venture on any extracts from this section of the work; all parts of the argument are interwoven, and to separate any would hardly do it justice. The misty doctrine, *similia similibus curantur*, the infinitesimal doses, the theory of potentizing, the itch hypothesis, are all discussed with equal vigour. Under the head of infinitesimals, many of the ingenious formulæ which have been employed to express these marvellous quantities are given. One or two may be quoted:—

"Soon after the first promulgation of Hahnemann's doctrines it was suggested, that if the decillionth part of a grain have any efficacy, an ounce of medicine (epsom salts) would be sufficient to physic all the Calvinists of Switzerland. But later and careful systematic calculations have shown that this is stopping very far short of the truth. The 10th solution alone would, as M. Cass

has shown in the *Journal de Pharmacie* for 1845, require a body of water 500 times greater than the bulk of the Lake of Geneva, or a sea somewhat larger than the Gulf of Venice. To make the 11th solution, a quantity of water greater than the Mediterranean would be necessary; the 12th solution could scarcely be accomplished in an ocean 500 fathoms deep, and covering the *whole* surface of the earth; while the 30th, or decillionth solution, to be performed on 15 grains of a homœopathic medicine, would require a layer of water 1,300 yards in depth, and extending over a space *equal to the whole area of the solar system*. If the whole solar system were buried in an ocean extending in depth from the sun to Neptune, it would not form a sufficient medium for dissolving the same quantity of medicine down to the 500th dilutions of Drs. Korsakoff and Grosse."—P. 157.

The itch hypothesis is one that bothers the homœopaths much; the more enlightened perceive that it must be abandoned, but the true followers of Hahnemann still stick to it. One of these wiseacres, with cruel logic, has proposed to administer the itch insect to cure all the ills that flesh is heir to. Faugh! even an infinitesimal dose of Scotch fiddle would be sickening, though all the water from here to Neptune were used to dilute it. The homœopaths would be wiser if they kept the itch in its natural place, viz., in the palms of their hands, and did not cram it, really as well as figuratively, down the throats of their patients.

At page 211, Dr. Bushnan gives Hahnemann his *coup-de-grace*, by summing up the conclusions to which the strict induction has led.

We cordially congratulate Dr. Bushnan on this useful work, and we beg all our brethren to *arm themselves with it*, if the enemy invade their territories.

Mr. Brodribb's pamphlet is a smart, clever, and less professional attack than Dr. Bushnan's. It is very clearly written, and the successive exposure of the system is ably managed. The pamphlet has now reached a second edition, and will, we trust, go through many more. We would recommend such practitioners as have patients who are becoming globulistic, to send them a copy of Mr. Brodribb's pamphlet.

Climate of Italy in Relation to Pulmonary Consumption; with Remarks on the Influence of Foreign Climates upon Invalids. By T. H. Burgess, M.D., etc., lately Physician to the Blenheim-street Dispensary. Pp. 206. London: Longman, Brown, Green, and Longmans. 1852.

Time was when only the most wealthy sought restoration to health from residence in the sunny South. It is not so now; steam has practically reduced the distance, and with it the cost; and hosts of individuals, instead of solitary sick men, ask, Where shall I spend the winter?—Which is the best place to reside in during the summer?

This book is one of the best English medical guides to those desiring answers to the above questions. Dr. Burgess has himself resided in various parts of Italy, and speaks with the authority of a practical man.

"The purpose of this volume is to show," says its author, "that to send *consumptive* patients to Italy, or to the South of France, for the benefit of their health, is a mistake;" and in furtherance of his object Dr. Burgess points out the peculiarities of the climate of each of the favourite places resorted to on the Continent by consumptive patients, and their injurious effects. Before recommending to this class of patients a journey to the classic regions of the South, we strongly advise our professional brethren to run through Dr. Burgess's volume.

Annals of Anatomy and Physiology. Conducted by John Goodsir, F.R.C.S. Lond. and Ed., etc. etc. Part II. Edinburgh: Sutherland and Knox. 1852.

The first part of this work appeared in February, 1850, and was to have been continued quarterly. We are glad to see the second part, although two years have passed since the appearance of its predecessor.

The present Part contains the conclusion of Dr. Sanders's paper on the Spleen, and of Mr. Zinglas's elaborate description of the tongue of man and certain of the mammalia; an account of some experiments and observations made on the body of an executed criminal, by Kölliker and Virchow; notes, by Dr. Dobie, of the observation of cilia in two species of Grantia. The lithographic drawings of the first Part are replaced in the present by a very excellent plate on steel, illustrative of Mr. Zinglas's paper on the tongue of the chameleon, and by some good woodcuts.

We trust the success of this Part will be such as to induce its conductor to continue the publication at regular and tolerably brief intervals.

PROGRESS OF MEDICAL SCIENCE.

SELECTIONS FROM JOURNALS.

INFLUENCE OF MEDICINES ON THE TEMPERATURE OF THE BODY.

Three French physicians, MM. Dumaril, Demarquay, and Lecomte, have associated themselves together for the purpose of inquiring into the effect of medicines on temperature. Their experiments were made on dogs. To state the results briefly, they found that cantharides, in doses of from one to six grains, raised the temperature in six hours nearly four degrees Fahr.; canella, in a dose of from eight to ten drachms, elevated the temperature 3° Fahr.; and a second dose raised 2° more. One drachm of secale cornutum in five hours increased the temperature about 1½° Fahr. in five hours. Acetate of ammonia injected into the veins augmented also the temperature; put into the stomach, it produced the same effect in a less degree. Phosphorus, in doses of a grain and a-half to three grains, lowered the temperature. Strychnine produced no effect.

Certain purgatives were tried, such as colocynth, castor oil, etc.; the effects varied according to the dose; usually it was lowered, and then elevated to about 1½° Fahr. above the standard.

Emetics,—as ipecacuanha, sulphate of copper,—produced in small doses a little elevation; but, in large doses, lowering of temperature to the extent of 2° or 3° Fahr.—*L'Union Médicale.*

INFLUENCE OF SECTION OF THE PNEUMO-GASTRIC NERVES ON ABSORPTION.

An eminent veterinary surgeon, M. Bouley, (the son,) has presented to the Academy of Medicine an interesting memoir on the above subject, in which a remarkable fact has been made known. If the pneumo-gastric nerves be cut across in the horse and in the dog, and if a dose of nux vomica be then exhibited, the dog is poisoned, the horse is unaffected. It might then be supposed, that section of the vagi arrested absorption in the horse, but this is not the case. On examining more deeply into the subject, M. Bouley discovered that at no time does absorption go on from the stomach of the horse; the stomach, in fact, in the horse is a small sac, when compared with the enormous size of the intestines. It serves only as a conduit; and, in a few minutes after deglutition, (quelques minutes après leur ingestion,) the food is found in the vast cœcum, where absorption chiefly goes on. When the vagi are cut, the only effect is to paralyse the muscular fibres of the stomach, and thereby to cause the retention in that organ of the poison. In the dog, on the other hand, and in carnivora generally, the stomach is capacious, and food is digested in, and absorbed from it. Section of the pneumo-gastrics, although it paralyses its muscular coat, does not hinder absorption.—*L'Union Médicale, Mai* 6.

STARCH IN CUTANEOUS DISEASES.

Cazenave has lately employed, largely, powdered starch, pure or mixed with oxide of zinc or camphor, in various diseases of skin. In acute eczema, impetigo, herpes, acne rosacea, after washing the parts with a weak alkaline solution, and well drying them, some of the following powder is sprinkled, viz.,—oxide of zinc, one part; starch powder, fifteen parts. In prurigo of the axillæ, the anus, or the genitals, a quarter part of camphor is added. — *L'Union Médicale.*

SOLUTION OF NITRATE OF SILVER IN PRURITUS OF THE GENITALS.

Winternitz has lately recommended a solution of nitrate of silver (grs. iii. ad ℥i aquæ), in pruritus of the vulva or scrotum. The solution is applied three times daily, and two cases are given in which it succeeded after a fortnight's trial, when all other means had failed.—*Zeitschrift der Gesell. der Arzte zu Wien.*

CONSTITUENTS OF THE SPLENIC FLUID.

In the fluid obtained by boiling a spleen in water, Scherer has discovered that, besides some of the constituents of the juice of flesh, some nitrogenous principles are present, viz., uric acid and a body hitherto unknown, for which he proposes the name hypoxanthin. The formula for the latter is $C_5 H_2 N_2 O$. Hypoxanthin is a powdery crystalline mass, soluble in 1090 parts of cold, and in 180 parts of warm water; heated with nitric acid, it forms a

yellow stain, which liquor potassæ, in the cold, turns red, and, with heat, changes to a lively purple, like murexid. The composition of hypoxanthin is of great interest, as may be seen by placing together its formula, and the formula of zanthin, as determined by Liebig and Wöhler, and of uric acid:—

Hypoxanthin	$C_5 H_2 N_2 O$
Zanthin	$C_5 H_2 N_2 O_2$
Uric acid	$C_5 H_2 N_2 O_3$

Hypoxanthin has been found, not only in the spleen of men and oxen, but in the fluid pressed from the muscular substance of the heart. Also, very lately, Gerhard, a pupil of Scherer's, has detected it in small quantities in the blood of oxen.

In addition to uric acid and hypoxanthin, Scherer has found in the splenic fluid other bodies, viz.:—

1. A new nitrogenous crystallizable body, which resembles, excepting in containing no sulphur, the bile principle; he terms it lienin.

2. An albuminous substance, in combination with much iron.

3. Iron in combination with acetic and lactic acids.

4. A carbonaceous pigment, analogous to the colouring matters of urine and muscle.—*Canstatt's Jahresbericht, Erster Band, Neue Folge*, 1852, *pp.* 91, 92; *and Verhand der Phys. Med. Gesellschrift in Würzburg, Zweiter Band, p.* 298.

COMPOSITION OF THE SUCCUS ENTERICUS.

The composition of the intestinal fluid has lately been made the subject of an inaugural dissertation by Zander, a pupil of Bidder and Schmidt. An abstract of it is given by Scherer. The fluid was obtained by tying the ductus communis choledochus and the pancreatic duct, and then making an intestinal fistula; it was semi-fluid, stringy, colourless, always alkaline, though not always equally so. It contained, in 1000 parts, from 30 to 38 parts of solids, of which from 15 to 25 were soluble in alcohol, and from 5 to 13 were insoluble. It contained no albumen. It was found to possess the properties of dissolving flesh and coagulated albumen, and of changing starch into sugar. The pancreatic fluid and the bile did not appear to heighten the power it possessed of dissolving albumen.—*Canstatt's Jahresbericht*, 1852, *Erster Band, p.* 100.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

THE MEDICO-STATISTICAL SOCIETY.

In a former letter, we mentioned, that Dr. W. Gairdner had brought the subject of the registration of deaths under the notice of the Medico-Chirurgical Society, and that, acting on his representation, a Committee had been formed to consider the scheme which Dr. Gairdner had proposed. That Committee reported most favourably, and advised the Society to endeavour to work out the plan as originally advanced. To this proposal an objection was taken, chiefly on the ground, that it was *ultra vires* the Medico-Chirurgical Society to take up the subject of the registration of deaths, or to vote a sum from the Society's funds for that purpose. Subsequently, the report of the Committee was agreed to by a decided majority of the Society, but it was deemed advisable, on account of the feeling entertained by the Committee, to dissociate the proposed scheme from the Medico-Chirurgical Society, and to afford an opportunity to those who felt interested in it, to countenance it as a separate and distinct undertaking. With this view, there has originated the Medico-Statistical Society, of which the following gentlemen are office-bearers:—Dr. Alison, president; Drs. Christison and Begbie, vice-presidents; Drs. Maclagan, Seller, Newbigging, W. Robertson, and R. Mackenzie, members of Council; Dr. Taylor, treasurer; Drs. W. Gairdner and J. W. Begbie, registrars and secretaries.

A considerable number of medical men in Edinburgh and Leith have already become members of the Society, and, counting from the first day of the present month, the registration has commenced. The distinctive peculiarity which it is the design of the system adopted by the Society to carry out is, that medical men shall record as many of the morbid phenomena in each case as may appear necessary to explain the event, and that all the phenomena so stated shall be separately registered. It is within the contemplation of the Society at some future period to take up the consideration of any question, the determination of which may appear to require the co-operation of a number of medical men. Meantime, the Society confines its attention to the main object of its foundation, the registration of causes of death. Convenient schedules are now in the hands of the members; these, as they become filled up, are forwarded to a registrar, whose duty it is, if necessary, by a personal interrogation of the reporter, to amplify the information each schedule contains, but especially to arrange all matters of nomenclature as regards the individual cases, and to register the causes of death according to the Society's approved nosological table. From the interest, indeed enthusiasm, with which the members of the Society are already prosecuting the registration, we venture to predict a brilliant and successful career. The experiment the Society has undertaken is a very useful one, and may lead to very important results, even to a modification in the existing national systems of registration. We shall, therefore, take many opportunities of informing the readers of the *Medical Times and Gazette* of the progress and success of the Medico-Statistical Society.

LEGACY OF 30,000*l.* TO THE EDINBURGH INFIRMARY.

We are informed, on what we consider to be very good authority, that the above munificent sum has been left to this noble charity. Large as the sum is, it will not appear an inexhaustible one in the funds of an Institution whose average expenditure exceeds 8000*l.* per annum, and which, during the prevalence of epidemics, has often greatly surpassed that. We have always considered the case of the Edinburgh Infirmary a peculiarly hard one; it is not merely a local hospital, but has for many years been the dispenser of benefits to large numbers of the poor of Scotland and of Ireland generally. Nevertheless, its resources have been entirely dependent on voluntary contributions, and these mainly derived from the citizens of Edinburgh.

How different the case has been with the Dublin hospitals, for example; all of which receive a yearly contribution from Government. Till recently, this contribution, in the case of the Richmond Hospital alone, amounted to 16,000*l.* The funded wealth of the London hospitals, too, contrasts strikingly with the small capital, too frequently cut in upon, of our Metropolitan Infirmary. We only hope that a better time is coming; and that it will soon appear the duty of Parliament to contribute directly to the prosperity of an institution at once one of the noblest and most useful in this Kingdom. The generous bequeather of the 30,000*l.*—Dr. Paton, of Torryburn, in Fifeshire—has made one curious, but easily attended to, restriction. He appears to have had no very good will to clergymen; at all events, he prohibited the presence of any clerical functionary at his funeral, and decreed that no divine shall at any time take part in the direction of his property and legacies. Hitherto, it has been too much the fashion here for those who have had large sums to bequeath, to order the foundation of a charity and the erection of an hospital which should perpetuate their name,—a practice which savours more of pride than of true generosity. It is partly owing to the existence of this fashion, that we have now, in Edinburgh, to deplore the meagre funds of one single hospital for the sick, while we see hundreds of thousands squandered on the erection of gaudy palaces, in which children are reared and educated away from, and therefore not subject to, required and ordained parental authority. We sincerely hope, that the generous example of Dr. Paton may be extensively followed; and we feel proud, that the example should have been set by a medical man,—the bequeather having been a retired medical officer of the East India Company.

DEATH OF DR. WILLIAM THOMSON, OF GLASGOW.

We have to record the death of Professor William Thomson, of Glasgow, which took place in Edinburgh on the 12th inst. Dr. Thomson was in his 50th year. Since 1848 he had laboured under an affection of the heart, and latterly had suffered from many and severe attacks of bronchitis, and from enlargement of the liver. Dr. Thomson had come to Edinburgh on the 10th, for the purpose of seeing some friends, but became suddenly worse on Tuesday evening, and, after a few hours, expired. Dr. Thomson was the eldest son of the distinguished Professor, John Thomson, and brother to Dr. Allen Thomson, presently Professor of Anatomy in Glasgow. The deceased Professor graduated at Edinburgh in 1824, became a Fellow of the College of Surgeons in 1825, and of the College of Physicians in 1833. Up to 1841, he continued to reside and to practise in Edinburgh; but in that year, on the death of Dr. Badham, he was appointed Professor of the practice of physic in the University of Glasgow. Dr. Thomson was the author of a work on diseases of the liver, published at the time he held the office of physician in the Edinburgh Infirmary. He was also the contributor of various articles to the "Library of Medicine." Dr. Thompson was one of the earliest to describe the spurious melanosis of the lung, or miner's phthisis; and was the author of a very interesting notice of his father's life in the *Edinburgh Medical and Surgical Journal.*

CHAIR OF THE PRACTICE OF PHYSIC IN GLASGOW.

The lamented death of Dr. Thomson has rendered this appointment vacant. As candidates for the chair, we have already heard the names of Dr. Halliday Douglas, Dr. W. T. Gairdner, and Dr. Alexander Wood, of Edinburgh; besides those of Dr. Harvey, of Aberdeen; and of Drs. Andrew Anderson and Ebenezer Watson, of Glasgow. The presentation to this Professorship is in the gift of the Crown.

GENERAL CORRESPONDENCE.

THE LATE EDINBURGH QUARREL.

[To the Editor of the Medical Times and Gazette.]

Sir,—In reference to your editorial remarks on the "Last Edinburgh Quarrel," permit me to put you right on one or two points, as to which you have been either imperfectly or misinformed.

1. I did not originate the report of hæmorrhage; it was current for days before I had even heard of the case at all. 2. My "gossiping" in regard to it consisted of speaking to four medical men; and, in each case, in answer to questions casually put, as to what I knew or believed as to the cause of death. 3. The opinion of Dr. Christison as to the cause of death, was not, and could not have been, a decided one. He at first suspected hæmorrhage; and, having been called but a few hours before the patient's death, only arrived at his ultimate opinion through data afforded by Dr. Simpson. 4. The talk in the Profession as to the case, was not of the nature of "gossip," but respected the large and important question, whether such operations are ever warrantable. 5. The stain of the mattress was not "very trifling;" considerable bleeding is admitted to have occurred; and, consequently, "the report of bleeding is" not "evidently altogether incorrect." 6. I have never met, nor have I been asked to meet, any homœopathic practitioner professionally since the passing of the anti-homœopathic resolutions of the two Colleges. 7. My complaint against Dr. Simpson was, not that he had written disparagingly of me to Dr. Christison, but that he had circulated in the Profession, during several weeks, letters to Dr. Christison, containing charges against me and Dr. Matthews Duncan, not only without any intimation whatever to Dr. Christison, Dr. M. Duncan, or to me, but with care that the document in circulation should not reach the two last named and most interested,—a fact which has not been and cannot be denied. I am, &c. James Miller.

51, Queen-street, Edinburgh.

ON THE CLAIMS OF THE MEDICAL BENEVOLENT COLLEGE TO THE SUPPORT OF THE PROFESSION AND THE PUBLIC.

[To the Editor of the Medical Times and Gazette.]

Sir,—Although I am very unwilling to intrude myself upon the notice of my professional brethren, yet, as it has been intimated to me, that, at the present moment, the interests of what I know to be a most admirable Institution—the Medical Benevolent College—might be promoted by a brief exposition of its claims to professional and general support, I have felt that, in such a cause, no personal scruples ought to be allowed to prevail. With this conviction, I have undertaken to submit a few considerations to the notice of your readers. But, before doing this, it is but due to those whose support it is desired to conciliate, to state, that I have not ventured to make this appeal without having deliberately and carefully investigated the principles upon which this Benevolent Institution is based, the objects proposed to be carried out, and the means by which they are to be realised. The pressure of many engagements, joined, I may add, to the desire of watching the development of the plan when first submitted to the Profession, for some time prevented me taking any active part in the preliminary proceedings. Latterly, I have, as a member of the Council, personally participated in the deliberations of that body, and I have thus acquired a full and complete insight into what it is no misnomer to style a "national undertaking." The principal, and, as I would respectfully submit, the sufficient claim which may be urged on behalf of this Benevolent College to the general support of the Profession, is the comprehensiveness of its character. It secures all the objects that the most enlarged philanthropy could suggest, or that the most varied wants could require. It provides a home for the widow, a retreat for the less fortunate of our professional brethren; and a boon inestimable—a sound, superior education—for the sons of duly-qualified medical practitioners, at a cost so very moderate, as to place it within the reach of the great body of the Profession. It had been the intention, as I am informed, of the gentleman to whom the high merit of originating and vigorously advancing this great scheme is due (Mr. Propert) to provide annuities for the solacing those needing them in declining years,—a point which was only abandoned on the consideration, that such a procedure might seem to trench on the operations of another most admirable Institution. But although for the present no direct pecuniary aid is contemplated, such assistance will indirectly, and in its best form, be administered by the admission of a certain number of "foundation scholars," who will be entirely educated, clothed, and maintained by the College; nor will the elderly inmates be overlooked, inasmuch as the laws give to the Council a discretionary power of making money contributions to the "residents," according to the state of the funds. The Medical Benevolent College affords, in its several departments, a most suitable opportunity, both to individuals and to Societies, to secure the advantages just enumerated to those members of the Profession to whom they would be a welcome boon, since the Council have the power of granting to parties, upon the payment of a certain sum, the right of nominating "residents" and "scholars." When the Institution shall be in actual operation, there can be no doubt that many benevolent individuals, actuated by friendship and philanthropy, will avail themselves of this provision; and, at the present time, several local Medical Societies are, with that object, contemplating the presentation of considerable sums to the funds of the College, in order to expedite its erection.

An Institution embracing so many admirable objects appears to merit the combined and active support of all classes of medical men. Our professional brethren may aid in this goodly work of beneficence, not only by pecuniary contributions, but also by acting in all parts of the country as "local secretaries and treasurers." It is not too much to affirm, that a deep debt is due to the Profession from the public. There is in this community no class which renders so many and such important unpaid services; and is there a family in this kingdom that does not feel they have, perhaps under the most distressing and delicate circumstances, received from their medical attendants benefits which no money could repay? In the midst of pestilence, again, the practitioner of medicine is ever at his post; and how many are the heroes who, in administering to the victims of fever and of cholera, have laid down their own lives an offering to the sufferings of humanity. Many noblemen, prelates, and other distinguished individuals, have already contributed to the funds of the Benevolent College; and, doubtless, their number might be greatly increased by active and judicious exertions.

In conclusion, I would remark, that the success of this Institution may be regarded as secured; the large sum of nearly 10,000*l.* has been obtained; and, mainly owing to the exertions of one individual, a most eligible site for the requisite building is about being conveyed to the trustees. A plan, combining all the most important improvements in construction, has been submitted by the architect; and a most zealous and intelligent Council, after having prepared an excellent code of laws, will watch over the progress and prosperity of the College. In order speedily and fully to realise the great objects contemplated, all that is now required is an earnest and combined effort on the part of all ranks of the Profession; and, when it is recollected, that, in addition to its other philanthropic objects, this is also the cause of the widow and the orphan, we may, in humble reliance on the Divine blessing, confidently anticipate a happy and triumphant result. I am, &c.

Highgate. R. D. Grainger.

TREATMENT OF NÆVUS.

[To the Editor of the Medical Times and Gazette.]

Sir,—Since my letter "On the Treatment of Nævus" appeared in your Journal, I have been made aware, that the subcutaneous ligature for nævus was advocated some time ago by Mr. Curling. The paper to which I would allude is styled, "Observations on the Treatment of Nævi Materni, with Cases of Removal of these Growths from different Parts of the Face without Deformity." It appeared in the *Medical Gazette*, January 26, 1850. Case 2, in this paper, is headed, "Mixed Nævus of Lower Eyelid—Failure of Setons—Cure by Subcutaneous Ligature, without Disfigurement or Loss of Skin." In this case, the author surrounded the base of the tumour subcutaneously, and tightened the ligature by repeated traction. Had I known of this communication, I should probably not have asked for a column of your valuable pages; certainly I should not have done so without, at the same time, making reference to Mr. Curling's paper. I must apologise to you, Sir, and to my friend Mr. Curling, for ignorance on the one hand, and apparent disregard on the other.

Without endeavouring to justify myself, I may be allowed to state, that, in the year 1845, while I was house-surgeon at the London Hospital, I had occasion twice to tie nævi subcutaneously. On both occasions the nævus was small, and the ligature answered admirably. In November of the same year, I made the diagrams, which appeared in your number of last week, for the late Mr. Andrews, of the London Hospital, before I applied, with him, the subcutaneous ligature to a small nævus situated on the face of a child, a patient of Mr. Andrews. This mode of applying the ligature appeared to me to answer the destruction of nævus so perfectly, without interfering with the integrity of the skin,—without, consequently, raising the ugly scar that is necessarily left when the skin is included in the ligature,—that I prepared, at that time, a few lines in recommendation of this subcutaneous treatment of nævus. I was then, however, going abroad, and the communication was allowed to remain in my note-book until the circumstance at St. Mary's Hospital called it forth.—I am, &c.

14, Brook-street, Grosvenor-square. B. E. Brodhurst.

CYST ON THE SCALP OF A NEWLY-BORN CHILD.

[To the Editor of the Medical Times and Gazette.]

Sir,—A short time since I was sent for by a midwife, to see a child just born, and which both she and the nurse were afraid to dress, owing to some irregularity in its formation. On arriving, I found a large bag, composed of the integuments covering the cranium, the base of the tumour extending from the vertex partly down the occiput, and being there about an inch and a half in diameter, but expanding to a circumference of about ten inches; and hanging down the back as far as the scapula, there were two or three slight abrasions, probably produced by its passage through the pelvis, from which there was a slight exudation. I could not ascertain whether it communicated with the interior of the cranium; but, as there was every probability of sloughing taking place, I determined on puncturing the tumour, and obtained from it about two pints of bloody serum, and hoped, by applying pressure, to prevent any further collection in the cyst; however, in two or three days it again filled, and, as there appeared to be a great chance of its bursting, and the child was much emaciated, I proposed to the mother to again evacuate the contents, and that probably it might be removed by operation. This she objected to, and the consequence was, as I anticipated, that the sac burst a day or two afterwards, when the child was brought to me, and, as on minute examination the tumour appeared quite unconnected with the brain or its membranes, I determined on dissecting a flap of integument, and removing the remainder; but, after making the first incision, I found this would be impracticable, as the child was much exhausted by the hæmorrhage that followed; consequently I passed a ligature round the pedicle of the tumour, but owing to the state it was in from having burst, I deemed it necessary to remove the whole mass, (the child at the time being in a most exhausted state,) and afterwards applied cold-water dressing to the surface. On the second day after the operation, on removing the dressing, I was much gratified at finding a healthy surface to the wound about the size of a shilling; the child had somewhat rallied, and I believe if the cyst had been destroyed earlier the child would have lived,—as it was it lingered for nearly three weeks. I see a similar case was presented in 1844, before the Academy of Sciences, by M. Moreau, and that both he and M. Velpeau recommended no operation, but were opposed by MM. Berard and Blandin. In this case the child must have died without the operation.

Gosport. Fred. Lowes.

SULPHURIC ACID IN DIARRHŒA.

[To the Editor of the Medical Times and Gazette.]

Sir,—If you deem the following communication worthy of a place in your able Paper, you will much oblige me by inserting it.

While assisting William Sankey, Esq., of Sutton Valence, one of the many subscribers to the *Medical Times and Gazette*, having seen in its pages correspondence from different medical men relative to the efficacy of sulphuric acid in diarrhœa, and the following cases having come under my care, I determined on testing its therapeutic powers in that disease.

Mary Wbenham, aged 2 years, was brought by her mother to the surgery, suffering from severe diarrhœa and tenesmus, with a copious discharge of blood with each motion, also acute pain when evacuating the contents of the bladder; pressure over the abdomen caused extreme agony. On testing the urine with blue litmus, I found it had a highly acid re-action.

I ordered a mixture of mist. cretâ, with tinc. catech. and opii, and small doses of hyd. c. cret., rhei, and Dover's powder.

Having persisted in this treatment for some days with little, if any benefit to my patient,—the child, hitherto a remarkably fine, healthy-looking one, was now, to use the mother's expression, "falling out of its clothes," and had lost the use of its lower extremities,—as a last resource, (having tried the ordinary astringents, including acet. plumbi, in vain) I prescribed, April 10th—℞ Acid. sulph. dil. ℥iv., syr. simp. ʒj., aquæ ʒss. M. to be taken three times a day.

13th.—Diarrhœa not much lessened; pain slightly abated; not so much blood in the motions. To continue medicine.

15th.—Stools lessened in number; pain much relieved; blood still continues, but reduced to half in quantity.

18th.—Better in every respect; diarrhœa has altogether ceased, as also the blood.

25th.—The child has regained flesh and strength since my last visit; and I am happy to say the little sufferer is now enjoying excellent health.

My second case was that of an old woman suffering from occasional attacks of diarrhœa, which, she states, always leave her in an extremely low, weak condition, and usually continue a fortnight each time. I at once prescribed the acid in scruple doses, and with the most satisfactory results; as, after she had taken a second mixture, she sent to thank me, and returned the bottles; which latter circumstance, I need not inform you, generally indicates, that the doctor has taken his leave.

The third and last case that came under my care occurred in the person of a child attacked with the diarrhœa that so often accompanies dentition.

Without administering any other remedies, I ordered the acid in doses of four minims three times a-day, as in the first case, and in three days the purging ceased.

Remarks.—I am not aware whether any of your readers that have made trial of the acid have observed a peculiar yeast-like appearance of the stools on the third or fourth day after its administration. In the above-mentioned cases I have particularly remarked this occurrence.

I regret, Sir, exceedingly, having taken up so large a space in your valuable columns; but, trusting that the importance of the subject will be sufficient apology, I am, &c.

Sutton Valence. T. E. O'L.

THE ELECTORAL PRIVILEGES(?) UNDER THE NEW CHARTER OF THE ROYAL COLLEGE OF PHYSICIANS.

[To the Editor of the Medical Times and Gazette.]

Sir,—You would much oblige many of your readers by publishing the names of the gentlemen who concocted the new Charter of the College of Physicians. Is it got up by the "Council"? If we knew the men, we should be able to guess what they have been aiming at, for, without some such clue, it is really very puzzling to find it out. Take, as an instance, the limitation of the Presidency to one of the first fifty Fellows. What good can it do to restrict the choice of the College to those who were admitted twenty or thirty years ago? Is it, that the body is so utterly democratic or juvenile, or given to change, that a stand-fast-on-the-old-times gentleman is necessary to ballast the vivacious movements of the College? The "choice of the College," did I say? I ask pardon of the politic concoctors, for attributing to them so shamefully radical and revolutionary a proposal. I ought to have said the choice of the "Council," for the "nomination" of the President rests with that body. The Council consists of sixteen fellows, of whom four only go out of office annually, being re-eligible after being one year out of office. These gentlemen "nominate," and then the (poor) fellows of the Corporation elect. Proxies not allowed, nor travelling expenses to country fellows. All I can make of the matter is this,—that the present snug clique of regents mean to continue their rule under the new Charter. As for the great body of physicians in town and country having an opinion as to whom they would rejoice to place at their head—that the concoctors have never thought of. Would it not be well, that they be reminded such a body really exists, and that the members thereof may possibly be able to decide who is capable of fittingly filling the office of President without the tutorship of the "Council"? They might, *exempli gratiâ*, desire to elect Sir James Clark or Sir Charles Hastings;—but no! those gentlemen would be alike disqualified, not being among the first fifty.

The same principle runs through the whole Charter. The President has the patronage of appointing the "Vice-Presidents," in number four; but he can only appoint from the first fifty fellows—the quinquagesimal squad of sexagenarians—honour to their reverend antiquity! This is cautious, when it is remembered,

that the most juvenile fellow possible must be at least 30—an age when a man may be a bishop, or Prime Minister, or monarch of the realm, or Commander-in-chief, with the most perfect reliance on his steadiness and judgment. With a vigour rather astounding, the Charter gives a little more latitude to the President in the nomination of the "Treasurer" and "Registrar," for his choice is not restricted to the first fifty fellows; but then his nominee has to undergo the chances and mischances of an election by the fellows, which, of course, is a powerful check upon any escapade the venerable, the quinquagesimal-sexagenarian—annually re elected—President may commit. So, also, the Council is not restricted in its nomination of "Censors" to the first fifty fellows; but in this, as at other College elections, it is a special rule (to secure due deliberation), "that proxies shall not be allowed."

I will say nothing about the poor shadowless "members of the College;" the fact being, that such men have no business in the College at all. If they are not fit to take a share in the election of a President nominated out of the first fifty fellows by the Council, are they fit to practise their art?

I am, &c. A JEALOUS QUADRAGENARIAN,
(*Inceptor*) Candidate for the Presidency of the College of Physicians.

GALVANISM.

[To the Editor of the Medical Times and Gazette.]

SIR,—As galvanism is become a fashionable remedy for many complaints of deficient innervation, it seems to me the Faculty should pronounce some judgment on the best mode of using it. I believe we are generally but little acquainted with the practical part of this remedial agent; and I for one wish to seek some information from yourself or correspondents on this subject. The advertising men propound two contrary methods. Some furnishing us with an electro-galvanic apparatus, which gives a series of slight shocks, assert their mode to be the best, and deny the claim set up by those who contend that the shocks do harm and no good; and that they pass an uninterrupted current, scarcely or not at all felt by the patient at the time, but, nevertheless, restorative of impaired function of this or that part. Now, the question I shall be glad to be informed better on is, as to whether the galvanic current can be really affirmed to pass along the nerves for a length of time, in a manner not to be felt, so as to be opening, as these men assert, an obstructed or paralysed nerve track, and, by degrees, make it again patent to its former *vis nervosa*. They also assert, that the shocks interrupt and exhaust the little *vis insita* remaining; while the advocates for the shock contend for its being a salutary stimulant, and that the inappreciable current can neither be said to be a current at all, nor to be anything but an empirical nostrum. Soliciting your notice to my inquiry, I am, &c.

A COUNTRY SUBSCRIBER.

THE INJUSTICE OF THE MONEY-PAYMENTS UNDER THE PROPOSED NEW CHARTER OF THE COLLEGE OF PHYSICIANS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your correspondent, "Medicus Anglicanus," did not point out the gross injustice of the money-demand on the *extra-urbem* licentiates. Some of us have been *quasi*-provincial members of the College for from twenty to thirty-five years, and the accumulated value of our money-payment made on admission cannot be less than from 60*l.* to 80*l.* for each. Further, by far the greater majority of the *extra-urbem* licentiates are British graduates, who procured their diploma solely at the instigation of the College, with an implied, if not an express promise, that their legal position should have a full recognition under any future legislative changes; and this is the mode in which the College would respect the law by which it exists, and its own honour! I am, &c.

AN INDIGNANT EXTRA-URBEM LICENTIATE.

LOOK AT HOME.

[To the Editor of the Medical Times and Gazette.]

SIR,—Under the head of "Look at Home," I have latterly noticed in your valuable Journal certain editorial articles and other communications bearing upon certain points of medical ethics which are well calculated to do good, and it is to be desired that this should be continued as a stereotyped heading to other articles and letters as long as any members of our noble profession shall be found to have recourse to any mean or dishonourable artifices for the purpose of securing practice.

Will you have the kindness to favour your readers with your opinion in reference to the following paragraph, which may be found in a little sixpenny pamphlet, entitled "Disease: its Analysis popularly Described." The writer has described a case of dyspepsia, and adds: "This state of things continued for some months, and, finding that the usual remedies which gave him relief failed one after the other, he called in medical advice, and medicines were prescribed which afforded ease, and freed him in some degree from discomfort; but if the remedies were suspended he relapsed into the same state as before. He soon felt that this was nothing better than a palliative treatment—a 'pottering' system, which brought with it no satisfaction. He could not, however, fathom the true cause of this, which arose from the medical attendant overlooking a very important item in the management of such a case—namely, the rigid scrutiny of the habits and diet of the patient.

"When the patient first applied to me," etc., and then follows the success of the writer's mode of treatment.

The writer of this paragraph is the youngest practitioner in the town, and yet he does not scruple to hold up to the public some older practitioner as a "potterer," and incapable of treating a common case of dyspepsia.

Do you think, Sir, that this is in accordance with strict professional propriety, or that it is calculated really to advance the writer in the estimation of that public for whom it was written? And do you not think that it is likely to injure a young physician, one grand object of whom should be to cultivate the good feeling and respect of his professional brethren? We seldom observe that any great reputation is reached and maintained by persons who do not scruple to sacrifice the reputation of others, and one passage so beautifully apposite occurs to my recollection in "an address delivered before the Dublin Obstetrical Society, by Dr. Montgomery," which I cannot resist the temptation to quote:—"I would fain impress upon you this truth, that the best means ever any man adopted to advance his own interest effectually and permanently, is to be tender of the reputation, and considerate for the interest, of others. There is no surer proof of an honourable mind, and conscious integrity of purpose, than a readiness to construe liberally the acts of others; to make allowances for defects, which, after all, may be only apparent, and to palliate errors in others, as far as that can be done consistently with truth, and a due regard to the welfare of those committed to our care. As, then, we value our own character, we should be tender of that of others. It is surely wretched architecture to attempt to build a reputation on the crumbling remains of that of another. What can be expected of such a structure, but that it will tumble about the ears of the builder, and perhaps bury him in the ruins? Rest assured, that, however secretly or cunningly any one may manage *ambiguas spargere voces*, the uncharitable insinuation will be disclosed; for such things, stone walls have ears, or, to use the language of Solomon, 'A bird of the air shall carry the voice, and that which hath wings shall tell the matter.' Be assured, sooner or later, those who follow this unworthy course will experience the truth of the Persian proverb, which says, that 'Curses are like chickens, and always come to roost at home;' and are not insinuations and detractions some of the worst curses of society? Be assured of this, that the ladder by which you can most certainly and safely mount to a high reputation, 'is the good opinion of your professional brethren.'"

This passage from Dr. Montgomery's address should be printed in gold, and placed in the most prominent place in the study of every medical man in the country; and, above all, should its noble sentiments be indelibly engraved upon the heart of every medical practitioner, and our Profession would indeed and truly be "God-like." I beg to enclose my card. I am, &c.

M.D.

BETHLEM.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your readers may be glad to know, that there are several Asylum appointments quite as good as the one proposed at Bethlem, even in a pecuniary point of view, if the difference of expenditure between London and the country be taken into consideration. Fortunately all counties do not adopt the Middlesex standard of medical remuneration. Ambition might lead many men to try for the Bethlem appointment, but, as you justly observe, few men would submit themselves to the various controlling powers in operation there.

The Board should meet as frequently as business may require;

and no delegation of authority to individual members thereof, or to Sub-committees, should be permitted.

The Superintendent should have a seat at the Board (without a vote) secured to him by the Rules. I have, and the only authority I feel myself bound to obey is, the opinion of the majority of the Board, duly expressed and recorded in a Minute.

Without this understanding a public officer may be worried to death by meddlesome Committeemen; with it, he may generally lead his Committee in the right direction, for, after all, public Boards consist of a majority of gentlemen.

I am, &c. A County Superintendent.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

John Bishop, Esq., F.R.S., President, in the chair.

OPERATIONS FOR OVARIAN DROPSY.

Mr. I. Baker Brown made some observations on two operations which he had lately performed for the cure of ovarian dropsy. These operations were somewhat novel, inasmuch as they exhibited ovariotomy in a modified form, and offered some pathological considerations of great moment in a practical point of view. Mr. I. B. Brown stated, that he had lately operated on a patient in St. Mary's Hospital, by excising a portion of the cyst, and returning the remaining portion within the peritonæum, and then closing the wound by sutures, leaving the fluid that might be secreted by the partial cyst to be absorbed by the peritonæum. This patient was convalescent in a fortnight, and would leave the hospital within a month from the date of the operation. The second case offered difficulties which ended in complete extirpation; this case, however, was doing well. Mr. Brown stated, that he should, with the permission of the Council, read a paper on the subject before the Society in May next, and therefore should not now dwell further on these cases.

LIGATURE OF THE EXTERNAL ILIAC ARTERY.

Mr. H. Smith exhibited to the Society a patient upon whom he had performed the operation of tying the external iliac artery on the left side, and the superficial femoral of the opposite limb. The external iliac had been tied a year and a half ago, for aneurism, high up in the thigh. The patient had remained well until the beginning of the present year, when an aneurism of the popliteal artery had appeared. For this the ligature was placed upon the superficial femoral artery two months since. The patient was now quite well, and was about to return to his work. Mr. Smith stated, that he had shown the patient to the Society, as it was a very rare thing to meet with a case where both vessels had been successfully ligatured on the same individual. There was one point of special interest connected with the first operation, to which he drew the attention of the Fellows. Some months after the iliac artery had been tied, a considerable protrusion had taken place, so that it was necessary for the patient to wear a truss; but, since he had been laid up to undergo the second operation, the hernia had disappeared, and did not present itself when the patient coughed. Nevertheless, for the purpose of obviating the chance of its recurrence, he had advised the man to continue wearing his truss.

Mr. Borlase Childs desired to ask Mr. Smith whether compression had been tried before the ligature was applied on either vessel; and, if not, why was it not tried?

Mr. Smith stated, that he had put the question fairly to the patient, as to whether he would have compression tried first or not, he having made up his mind to employ it if the patient desired it; but the man decided on having the ligature applied upon the external iliac at once. With respect to the second operation, he had advised the man to undergo the same process in reference to the femoral artery as he had done with regard to the external iliac, as he had so rapidly and effectually recovered from the first operation, and he had every reason to suppose that there would be the same success in this instance.

Dr. Crisp exhibited three specimens of

PERFORATION OF THE STOMACH.

The patients were all young women. Two stomachs were also shown, which demonstrated the *post-mortem* effects of the gastric juice. In one of these a large aperture was formed. Another specimen of perforation of the colon from dysentery was also exhibited. Dr. Crisp said, that his chief object in bringing these preparations before the Society was in relation to the discussion that took place after Mr. Leonard's paper. The contrast between the perforations from the *post-mortem* action of the gastric juice and from simple ulceration during life, was very marked. In the former, the aperture was larger, and its edges flocculent and woolly, the mucous coat being destroyed to a much greater extent than the peritonæal. In the latter, the opening was generally small, with well-defined edges. A drawing, showing the size of the last-mentioned perforations, in numerous cases, was placed before the Society. Dr. Crisp said, that the opinion he was the first to express at that Society, fifteen years ago, respecting the occurrence of these perforations in young women, and their dependence upon uterine derangement, had been fully verified by subsequent investigation. He differed from Mr. Leonard in many of his conclusions, more especially in the statement that the subjects of these perforations presented a healthy appearance. They were generally pale and chlorotic. He had never seen the sloughy state of the peritonæal coat, nor the ragged condition of this membrane alluded to by two of the speakers in the recent debate upon the subject.

Mr. Bullock exhibited a specimen of diseased bladder and kidneys, taken from a patient of Mr. Lane's, in St. Mary's Hospital, admitted March 23. He was a man 42 years of age, whose history was, that, while hunting fourteen years ago, he was thrown on to the pommel of the saddle, passing afterwards blood in his urine, and having cutting pain on making water, with more or less difficulty for seven years, when he had retention; this was relieved by catheters, and, subsequently, bougies were passed for a short time; he again had retention at the beginning of March, and has since had instruments passed up to a few days of his admission. When he applied to the hospital he complained of great pain in the pubic region and in the perinæum, and stated that he had not passed water for some hours. On attempting to pass an instrument great pain was caused; the attempt was therefore given up, and he was given a warm bath and an opiate; some urine passed in the bath. On the next day, a No. 3 wax bougie was passed without much difficulty, but the urethra appeared rather rough. The pain continued; a quantity of gelatinous-looking mucus passed on withdrawing the bougie; there was blood in the urine, which was consequently albuminous; he was given mercurial alkalies and leeches without any permanent benefit. On the morning of the fourth day, a small phosphatic calculus suddenly shot out into the urethra, about two and a half inches from the orifice; this was extracted by urethral forceps, with immediate relief; a quantity of mucus and some urine followed. The next day, however, the pain returned; more blood passed in his urine, and in the course of three or four days a swelling appeared in the perinæum: this was opened, and thick mucus evacuated; there was a little hæmorrhage. He gradually sank, and died on the 6th of April. Both kidneys were granular, large, and greatly injected; the right ureter contained about ʒij. of albuminous urine. At its termination in the bladder its coats were thickened, and the mucous membrane ulcerated for about one and a half inches. The walls of the bladder were greatly thickened; there were several small abscesses in its substance; the membranous, bulbous, and part of the spongy portion of the urethra for about three inches were ulcerated, and had a small communication with the wound in the perinæum, about two inches and a half from the orifice. About half an inch of the urethra was coated with lymph, which was intimately adherent to the mucous membrane.

ON THE NATURE AND TREATMENT OF EPILEPSY.

Dr. Radcliffe then read a paper on this subject. He first drew attention to the temperament of epileptics, and showed that this was distinguished by unequivocal marks of weakness and depression; signs of scrofula or some other cachectic disposition, of depressed and feeble circulation, of defective nervous activity, of muscular feebleness, might always be detected, but never the signs of true plethora or of hyper-activity in the nervous or any other system. When epilepsy had shown itself in persons distinguished by their genius and talent, it was in the state of exhaustion induced by the exercise of that genius or talent; when it was associated with insanity, the convulsive disorder coincided with the intervals of depression, and never with the periods of *quasi*-excitement. After describing the phenomena of epilepsy, he proceeded to point out the continuance of the same signs of depression and exhaustion, and to show that the change which had taken place was always one of aggravated depression and exhaustion. This he did by a special examination of the condition of the vascular and nervous systems. Immediately before and after the fit the pulse was shown to be weak and collapsed, and often irregular and slow, and, in the fit itself, little or no blood was found to be propelled into the vessels. This condition of the circulating system entailed a corresponding failure in the activity of the several nervous centres. He argued, also, that the brain was inactive, because the epileptic was silent, sad,

moody, and generally still, before his seizure; completely bereft of sensibility, consciousness, and volition in his seizure; and stupid, confused, and exhausted afterwards. He argued, also, from the true appearances found after death. He noticed the views of Dr. Davey and Dr. Henry Monro in connexion with insanity, as corroborating this conclusion. He advanced arguments to show that the medulla oblongata, spinal cord, and the smaller ganglionic centres, were in a corresponding state of inactivity. Dr. Radcliffe then insisted upon the absence of any local disorder as a cause of epilepsy, and said, that the only way in which any such disorder had to do with the matter, was in aggravating the general debility and prostration of the system. Under this head he went on to notice the views of Dr. Marshall Hall. He contended, that in epilepsy there was no proof whatever of any increased irritation in the spinal cord, any more than in the medulla oblongata and brain, but that there were abundance of proofs of a directly opposite condition. He doubted that trachelismus and laryngismus, with the consequent cranial and cervical engorgement, had any necessary connexion with epilepsy. He did this because there were distinct contractions in the limbs and elsewhere, before the occurrence of the spasmodic tightening of the muscles of the neck and larynx, and because the fit ceases when the congestion was at its height—so that he conceived Dr. Hall's theory had two insuperable difficulties to contend with,—the one that the fit had actually begun before it ought, (that is to say, before the congestion had shown itself,) the other that it ceased when it ought to have been most violent, (that is, when the congestion was at its height.) He (Dr. Radcliffe) argued, also, against the hypothesis of trachelismus and laryngismus, from its non-applicability to very many cases of epilepsy, in which cases, and in many other convulsive disorders, no such phenomena could be detected. He said, further, that this hypothesis did not account for the insensibility of epilepsy, for, in his opinion, this insensibility (which was much more frequently of the nature of syncope than coma) was, as a general rule, due to a syncopal condition of the circulation rather than to any venous congestion in the vessels of the brain produced by the spasmodic tightening of the muscles of the neck. The mere violence of the muscular contractions or convulsions in epilepsy, Dr. Radcliffe said, was no objection to the existence of the most positive prostration and depression; on the contrary, this very phenomenon was the best proof of the existence of that state. Muscular contraction, physiologically, as well as pathologically, was always (he asserted) the sign of some withdrawal of the nervous and other stimuli which appertain to the muscles, and never the result of the communication or importation of these stimuli, and for the confirmation of this opinion he referred to his published views on muscular physiology and pathology, and to the facts which had just been stated in connexion with epilepsy. Upon the treatment, he argued at some length against low diet, and in favour of the most nutritious food, with stimulant and corroborative drinks, and against over-exercise in favour of rest. Citing many other arguments, he conceived that the non-existence of vascular or nervous excitement, and the existence of a directly opposite condition, was itself an insuperable objection to bleeding and purging in this malady, and an argument for the necessity of stimulants and tonics, and all means which could corroborate the system. Narcotics, counter-irritants, and emetics were condemned. The convulsion-exciting properties of strychnia were stated to be an argument against, rather than in favour of, that drug. He objected, also, to tracheotomy in the cure of epilepsy, on the ground, that there were many cases of that malady in which the larynx was not sensibly affected, and in which the impediment to the respiration was rather owing to irregular action or spasmodic fixation in the thoracic muscles and diaphragm, than to mere closure of the larynx.

MEDICAL NEWS.

Medical Benevolent Fund.—The Anniversary Dinner of this Institution took place at the London Tavern, on Thursday last, the Earl of Carlisle presiding. We were gratified to witness a very full attendance on the occasion, and among those present may be mentioned:—Sir James Clark, Sir Charles Hastings, Dr. Forbes, Dr. Sylvester, of Clapham; Dr. Browne, of Dumfries; Dr. Burrows, Mr. Propert, Mr. Erasmus Wilson, Dr. Radcliffe, Mr. C. R. Hall, of Torquay; Mr. Edwin Saunders, Dr. Conolly, of Hanwell; Dr. Bright, Dr. Cowan, of Reading; Dr. Walter Lewis; Mr. Solly; Mr. Sankey, of Dover; Mr. Bottomley, of Croydon; Mr. Toynbee; Mr. Curling; Dr. R. Bennett; Mr. George Sampson; Mr. Squibb; Mr. South; Mr. Day, of Isleworth; Dr. Bushman; Mr. Lord, of Hampstead; Dr. Begley; Mr. Newnham, of Fareham; Dr. Daniell, of Newport Pagnell; Mr. John Churchill; Dr. Barclay; Dr. Sibson; Mr. G. N. Palmer; Dr. Seymour, of St. George's Hospital; Mr. Clement, of Shrewsbury; Mr. Lowdell, of Brighton; Dr. Jenks, of Brighton; Mr. Hunt; Mr. Bird; Mr. Norman, of Bath; Mr. Eyles, &c. &c. The dinner, as usual at this establishment, was excellent, and was musically enlivened by the talented performances of the following vocalists, under the direction of Mr. Ransford:—Miss Eyles, Miss Ransford, Mr. Holmes, Mr. W. E. Ransford. After the usual loyal toasts, the noble Chairman, in an eloquent speech, proposed, "Prosperity to the Medical Benevolent Fund," coupling with the toast the name of Mr. Newnham. Mr. Newnham having returned thanks, "The Royal Colleges of Physicians and Surgeons" were next severally proposed, and followed by other toasts. The contributions announced amounted to a considerable sum, of which we shall give particulars in our next, together with a more detailed account of the proceedings.

Royal College of Surgeons.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 14th inst.:—

Beddome, Henry Septimus, Hudson's Bay, North America.
Clarke, Richard, Beccles, Suffolk.
Drinkwater, James Pratchett, Shrewsbury, Shropshire.
Gurney, Richard Anthony F., Lilburn, Northamptonshire.
Hanna, Harrison, Belfast.
Hildege, James Graham, Dublin.
Lambert, George Prowd, Enfield, Middlesex.
Lucas, Robert, Bottisham, Cambridgeshire.
Mugliston, George Thomas William, Westham, Essex.
Shepherd, William A., Hon. East India Company's Service.
Sowerby, Thomas, Loughborough, Leicestershire.
Wadsworth, Godfrey B., Warwick-street, Regent-street.

At the same meeting of the Court, Messrs. Augustus Richard Richard Preston and Richard Jago Squire passed their examinations for Naval Surgeons; these gentlemen had previously been admitted members of the College, their diplomas bearing date, respectively, February 20, 1846, and July 17, 1846.

The College Lectures.—Professor Paget brings his interesting course of lectures, on Malignant Tumours, to a close this day (Saturday).

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 13, 1852:—

Ball, Tertius, Liverpool.
Balding, Daniel Barley, Barkway, Herts.
Brown, Alexander, E.I.C.S, Steeple Bumpsted, Essex.
Hemingway, Edward Vavasour, Leeds.
Lankester, Henry, Poole, Dorset.
Manley, John, Hurst-green, Sussex.
Ogilvie, William Mackay, R.N., Boughton Blean, Kent.

Obituary.—On the 6th ultimo, at Cairo, from the effects of a sunstroke, received four days previously, Charles Evans, Esq., late of Margate, surgeon, in his 39th year. On the 8th instant, at King Haithe-square, Lynn, Edward Manby, Esq., surgeon, formerly of East Reedham, Norfolk, aged 69. On the 13th instant, at his residence, the Lodge, Bedford, Nicholas Fitzpatrick, M.D., late of the Royal Artillery. On the 15th inst., in Hanover-street, London, in the 80th year of his age, William Winstanley, M.D., of West Cliff, Preston, one of Her Majesty's justices of the peace for the county of Lancaster.

Medical Appointments and Vacancies.—A resident surgeon apothecary is required at the Marylebone workhouse. Candidates must possess the double qualification; salary 150*l.* a-year, with board, lodging, and washing. Testimonials to be sent in on or before the 24th. Candidates admitted on the 26th. The apartments not suitable for a married man. At the Staffordshire General Infirmary a house surgeon and secretary wanted, Mr. Masfen having resigned. The double qualification required; salary 100*l.* a year, with coals, gas, washing, and furnished apartments. Board at the matron's table. Testimonials to be sent in or before the 2nd of June. Duties to commence at Midsummer.

Dr. G. Robert Rowe, of Cavendish-Square, has been appointed Physician to the East of England Life Insurance Company, (a Medical Managing Officer.)

Dr. Paris, President of the Royal College of Physicians, had an interview, on the 17th inst., with Mr. Secretary Walpole, at the Home Office, to present the annual Report of the National Vaccine Board.

Military Appointments.—93rd Foot: Staff-Surgeon of the 2nd class John Ramsay Brush, M.D., to be surgeon, vice Sall, who exchanges. Hospital Staff: Surgeon William Sall, M.D., from the 93rd foot, to be staff-surgeon of the 2nd class, vice Brush, who exchanges.

The Militia.—The House of Commons, on Monday night, resolved, by a majority of 90, that medical men should not be exempt from serving in the militia. By a preceding resolution, they exempted Peers. Surely, the authorities of the Colleges of Physicians and Surgeons have influence enough, at least in the Upper House, to cause the withdrawal of this most unjust and injurious resolution.

Charity for Hospital Purposes.—The Right Hon. L. Sulivan, and the Rev. J. H. Fisk, have each presented the sum of 50*l.* to the Charing-cross Hospital; and the Duke of Buccleuch has given 25*l.* to the same hospital. Mrs. Droop has given 30 guineas, and Mr. Wilson, 21*l.* to the Hospital for Children, to which Captain Gladstone, of the Royal Navy, has also contributed 10*l.*

In March, 1405 persons died in Bombay out of a population of a quarter of a million—171 from cholera. Eleven Europeans were cut off during the month.

Progress of Epidemics.—The yellow fever still prevails at Rio, the mortality being principally confined to the shipping. At Pernambuco, where the fever had partially subsided, it has returned with greater virulence, and some fatal cases have occurred in the city. In consequence of the existence of fever at these places, the Severn, mail-steamer, was placed in quarantine at Teneriffe, Madeira, and Lisbon. Four deaths occurred on board, but it is not stated those deaths were or were not occasioned by the yellow fever. At Lisbon, the passengers, 100 in number, were sent to the Lazaretto for eight days. The troops in Hong-Kong continue healthy, though the weather has been very unfavourable, and generally the colony is much freed from the late epidemic of small-pox. Dublin is reported to be suffering severely from a malignant fever. On this subject Mr. Reynolds put a question to the Chief Secretary for Ireland, in the House of Commons, the other night, as to what arrangements had been made to afford additional hospital accommodation to the sick poor; and he also inquired whether it were the intention of the Government to reduce the annual grants to the Cork-street Fever Hospital, and to other charitable hospitals in Dublin. He added, that he believed that malignant fever was increasing to such an extent in that city as to render the present hospital accommodation altogether insufficient. Lord Naas replied that, from the accounts he had received, he had great hopes that the prevalence of fever was somewhat on the decrease in Dublin. At all events, full and perfect hospital accommodation would be provided for all the poor who were attacked. With regard to the other question, the votes for the Dublin hospitals would be proposed in accordance with the estimates on the table. There the matter dropped; but we must express our hope, if the fever should increase and become an epidemic, requiring the establishment of special hospitals, that the remuneration of the medical officers will not be on the same scanty, insufficient, and paltry scale as heretofore.

[Advertisement.] — New Equitable Life Assurance Company.—Chief Offices, 449, West Strand, London. In consequence of several false and calumnious allegations which have been circulated respecting the proceedings of this Company, the Directors think it right to publish the following statement:—1st. That Dr. Robert Lee, F.R.S., has not resigned either the office of Chairman or that of Director. 2nd. That George Beaman, Esq., Vice Chairman, has not resigned either the office of Vice Chairman, or that of Director. 3rd. That since the business of the Company commenced, not a single Director has resigned, and that all the members of the Board, individually and collectively, are employing their utmost energies to promote the success of a Life Assurance Company which duly recognises the rights and valuable services of the Medical Profession. 4th. That the salaries of all the officers and clerks of the Company have been regulated with a strict regard to the duties to be performed, and an economical application of the funds of the Company. 5th. That not any Director is secured or awarded by the deed of settlement, nor by any other deed or document, an annuity of 1200*l.*, a gratuity of 1200*l.*, nor any gratuity or pension whatsoever. 6th. That the founder of the Company occupies only the same position in the deed of settlement as any other Director, and that it is not provided by the deed or any other instrument that he shall receive one shilling more than is to be paid to any other Director. That he has never made a charge for any personal expense incurred by him, nor for the time bestowed on his endeavours, continued for nearly a whole year in getting the Company registered. That he has received nothing for these services, and has declared that he will receive nothing beyond the unanimous vote of thanks awarded to him by the Directors, and policy and shareholders at the Annual General Meeting—an honour then gratefully acknowledged. 7th. That the balance-sheet, published pursuant to the Act of Parliament, on the 31st December, 1851, which shows the premiums up to that date; and the Report, dated 31st January, 1852, which shows the premiums up to that time, are both strictly and accurately correct, as may be seen by any policy or shareholder, who will take the trouble of inspecting the books. 9th. That, since the 31st December, 1851, the annual premiums on new policies have been, up to the 30th April, 1852, 3976*l.* 13s. 1d., making a total of premiums on new policies up to the last-mentioned date of 7459*l.* 18s. 10d., in a period of fifteen months, an amount of business which has naturally provoked much envy and misrepresentation. The Directors take no credit to themselves for what has been done, further than for propounding the principles which are characteristic of the constitution of the New Equitable Life Assurance Company. On the contrary, they cheerfully acknowledge, that the extraordinary success of the Company is attributable to the exertions and support of the members of the Medical Profession, who at once discovered both the elements of retribution and of justice in the Charter of the new Institution. —By order of the Board, John Thompson, Secretary, 15th May, 1852.

Mortality Notabilia.—The mortality of the Metropolis of last week exhibits a considerable increase on that of the preceding week. In the week that ended 8th May, the deaths fell to 972; in the week ending last Saturday, they rose to 1070. In the ten corresponding weeks of 1842-51, the average number of deaths was 907, which, if raised in proportion to increase of population, becomes 998. The deaths of last week, therefore, exceed the estimated amount by 72. Compared with the facts of the previous week, the present return discovers an increase in deaths caused by epidemics from 193 to 234, while in those from diseases of the respiratory organs the numbers are almost identical. There is an increase from 130 to 142 in deaths by phthisis. Diseases of the heart also rose in the two weeks from 37 to 45; those of the digestive organs from 60 to 74. Among epidemics the increase arises chiefly from small-pox, and in the next place from scarlatina. Zymoties in the aggregate produce at present considerably more than the average mortality of the season.

ORIGINAL LECTURES.

LECTURES

ON

THE PATHOLOGY AND DIAGNOSIS OF RENAL DISEASES;

BEING THE GULSTONIAN LECTURES.

DELIVERED AT

The Royal College of Physicians,

By GEORGE JOHNSON, M.D. Lond.

Fellow of the Royal College of Physicians, and Assistant-Physician to King's College Hospital.

(Concluded from page 154.)

Lecture III.

In two previous lectures I have given the pathological history of a form of renal disease which is characterised by a desquamation of epithelium from the uriniferous tubes, the object of the desquamative process being, as I have endeavoured to prove, the elimination of some abnormal products from the blood. To-day I have to speak of a disease, the most remarkable feature of which, is the absence of that desquamation which is characteristic of the first-mentioned malady. One of the best illustrations of the acute form of what I propose to call the non-desquamative disease, was afforded by the subject of the following case, for the notes of which, as well as for the opportunity of examining the urine and the kidney, I have to thank my friend Dr. Henry Monckton.

John Ager, aged 18, was admitted into the Dreadnought Hospital on the 1st January, 1850, with rheumatic fever. In the month of March he was convalescent, taking tonics, walking about, and reporting himself every day stronger and better. On the morning of the 15th March, while he was still up and dressed, he first directed attention to his legs, which were much swollen, as was also the scrotum. He was ordered to bed, and directed to keep his water, which he said was scanty and high-coloured. In the evening of the same day, he was much worse, having been seized with urgent dyspnœa, after eating a chop, and making rather a sumptuous and rapid meal at tea time. The anasarcous swelling had much increased, and the abdomen was distended. He had passed no water. An emetic of sulphate of zinc was given—a mustard poultice to the cardiac region, and the feet were placed in hot water. He soon became much easier, and being propped up in the upright position he fell asleep.

On the following morning, the 16th, the breathing was much easier; but wheezing sounds were heard over both lungs. The bowels had been freely opened, and the small quantity of urine secreted had been passed with the motions, so that none could then be obtained for examination.

The next day, the 17th, he was much the same; but, in the night following, he was seized with another fit of most urgent dyspnœa, so that life seemed instantly threatened. He was somewhat relieved by the same treatment as on the former occasion; but he could not sleep, and, on the following morning, he was still much distressed, unable to speak, and his features pallid and pinched. He was evidently weaker; pulse 130; loud wheezing sounds were heard over the chest. Some urine now obtained had a sp. gr. 1028, and formed an almost solid coagulum with nitric acid.

On the 19th of March, it was reported, that he had passed no urine since yesterday at noon; his countenance was anxious, and very pallid; pulse very irregular and weak; respiration, 48.

He gradually sank, without any increase of dyspnœa, and died about 10 p.m., within five days from the time when the dropsical symptoms were first observed.

The body was examined sixteen hours after death. The cellular tissue was everywhere loaded with serum; the face puffed; and the abdomen full.

The pleuræ contained recently-effused lymph and serum.

The lungs were in a state of engorgement, approaching to hepatization.

The heart was of moderate size, and all its valves were healthy.

The abdominal cavity contained much serum, and flakes of lymph.

A small quantity of urine, and a portion of one kidney, were sent to me for examination. The urine had a specific gravity of 1028. On the addition of nitric acid, it became almost solid with albumen. It was somewhat dark-coloured, but nearly clear, and free from cloudiness. After standing, it deposited some crystals of lithic acid, but no casts of tubes, epithelium, or blood corpuscles.

The cortical substance of the kidney was pale; the tubes were abnormally opaque, and had a yellowish tinge,—an appearance resulting from the condition of the epithelium, which was unusually opaque and granular—a departure from the normal condition very difficult to describe, though quite easily recognised. In only a very few tubes was there any appearance of a crowding of epithelium, the result of desquamation. The Malpighian capillaries presented the appearances so constantly observed when, during life, the serum of the blood has transuded through them. The walls of these vessels were opaque, and apparently thickened, so that the blood corpuscles within them appeared colourless and magnified.

A few months before I met with the case the history of which I have just now given, I had examined the kidneys of two patients, of whose history I knew little more than that they died from suppression of urine; and in both instances the kidneys presented the same appearances as were observed in the case of Ager.

These cases were the first by which my attention was particularly directed to that remarkable concurrence of phenomena which I have just now described, namely, a very scanty secretion of highly-albuminous urine, containing scarcely a trace of renal epithelium or of tube-casts,—urgent symptoms of suppressed secretion, often terminating fatally, and thus affording the opportunity of observing that there is nothing in the mere morbid anatomy of the kidney to explain the fatal consequences of the attack.

In order to arrive at the true interpretation of this form of disease, we must again advert to the phenomena of desquamative nephritis.

I have endeavoured to prove, that the abundant shedding of epithelium, which characterises that form of renal disease, is the result of a salutary effort to eliminate from the blood some abnormal products, the retention of which would doubtless lead to injurious consequences, while their ready escape from the blood is probably favoured by the free shedding of the epithelial cells, as the elimination of the scarlatina poison is effected by the desquamation which it excites on the surface of the skin. A consideration of these phenomena suggests the probability, that, in the event of there being conveyed by the blood to the kidney, any of those abnormal materials which are usually eliminated by means of the desquamative process, the *non*-occurrence of epithelial desquamation would be an unfavourable circumstance. The absence of desquamation in such instances is perhaps analogous to those cases of the exanthemata, in which the eruption is either entirely absent, or very imperfectly developed; and this depending not, as it appears, upon the blood being infected by a mild dose of the morbid poison, but upon some failure in the effort to eliminate it by means of the cutaneous eruption; the symptoms of blood-poisoning being, meanwhile, very urgent, and often quickly fatal. Instances of such an occurrence may occasionally be seen in the case of small-pox; and the case which I quoted in my last lecture from Sir B. Brodie, affords an illustration of what we may perhaps call an abortive carbuncle. Again: it has frequently been observed, that the most rapidly fatal cases of cholera are those in which there is either no purging, or a very scanty secretion from the bowels; the patients quickly sinking either from an excessive dose of the poison, or in consequence of some failure and imperfection in the effort to eliminate it.

With reference to all the instances which I have adduced for the sake of illustration, it is important to distinguish between the essentially beneficial tendency of the primary morbid phenomena and the secondary consequences, which may be injurious and even fatal. Thus, in a former lecture, I alluded to the fact, that an abundant desquamation of epithelium may so fill and obstruct the uriniferous tubes as to arrest the process of secretion within them. A copious eruption of small-pox pustules may destroy the patient by the excessive irritation and the exhausting discharges which they induce; and the abundant discharges produced by the cholera poison will so effectually drain away the watery portion of the blood as to destroy the life of the patient; and yet, in each of these instances, consequences more

speedy in their occurrence, and not less serious, would result from the absence of those pathological phenomena which a superficial observer might erroneously consider to be the essence of the diseases referred to.

A careful study of these and other allied phenomena, will show the importance of distinguishing the primary and essential cause of a disease from those outward and visible manifestations of it, which are in many instances the means adopted by nature for the removal of the evil, or for obviating its injurious effects. The distinction is not more important for the purposes of exact pathology than as being an essential condition for the correct and rational treatment of disease. It is evident, for instance, that the notion of scarlatina being primarily and essentially an inflammation of the skin, without reference to the condition of the blood or the designed end of the cutaneous eruption, would be a great error in pathology, and, applied to practice, would lead to serious, and even fatal results. The cutaneous heat and redness might be speedily removed by the influence of cold, but injurious consequences would certainly result from the suppression of the eruption.

Before I had learned to recognise this non-desquamative condition of the kidney, and to give to it what now appears to be the true interpretation, I had, on several occasions, based a favourable prognosis upon the idea, that when the urine, though scanty and highly albuminous, is free from sediment, and contains neither casts of tubes nor renal epithelium, the kidney is in a state of simple congestion or of functional disturbance, and therefore favourable for the patient's recovery. It was only after repeated disappointments, and painful proofs that I had sometimes given a too favourable prognosis, that I succeeded in separating the large proportion of error from the element of truth contained in the idea referred to.

From what has already been said, it will be apparent, that the absence of desquamation is the characteristic feature of the condition of kidney now under consideration. The diagnosis of such cases during life must be based partly upon positive, and partly upon negative evidence. To the first kind belongs the fact of a scanty secretion of highly albuminous urine, the colour of which is nearly normal, or perhaps somewhat darker and less transparent than usual; while evidence of a negative kind is derived from the observation, that the urine contains neither renal epithelium nor casts of the tubes. The absence of tube-casts is, however, not constant, for in certain cases, which I believe to be essentially of the same kind, as indicated by the absence of all signs of desquamation, the urine contains a peculiar form of tube-cast, the observation of which will assist in the formation of a correct diagnosis.

I believe that I shall best succeed in elucidating this point, by giving the history of a characteristic case, with the addition of such comment as is necessary to render the case intelligible.

George Henry Lewis, aged 45, of intemperate habits, had latterly been much reduced in circumstances, and had suffered from mental anxiety and an insufficiency of food: was admitted into the hospital under the care of Dr. Budd, on the 6th June, 1849. He was suffering from general anasarca and ascites in a great degree, and his body was covered with an ecthymatous eruption. He was very pallid, his breathing was difficult, and accompanied by a wheezing sound. His condition was altogether very pitiable. The dropsy had appeared a fortnight before his admission, and the eruption a month earlier. The sounds of the heart were normal.

The urine was scanty, rather light coloured, somewhat cloudy, of specific gravity 1012, becoming almost solid with albumen when boiled. After standing it deposited a pretty abundant whitish dense precipitate, chiefly composed of small transparent waxy casts, about one-thousandth of an inch in diameter, with scarcely any epithelial cells, and few, if any, blood corpuscles.

He was first put on milk diet, had a tepid bath every morning, and small doses of citrate of ammonia, with fifteen minims of ipecacuanha wine every six hours. He began to improve almost immediately.

It may be well to mention here, that for several years he had been subject to epileptic fits, one of the consequences, probably, of his extreme intemperance. During the continuance of the dropsy the fits returned with increased frequency, and he suffered much from headache.

The urine was frequently examined, and its condition was carefully noted. For a short time after his admission, he passed only 16 ounces of urine in 24 hours, but the secretion soon became much more abundant; and on the 18th June, for instance, it was 80 ounces, having a specific gravity of 1012. The casts continued to have the same character, but, after a time, some had a finely granular appearance,—a consequence, probably, of their having remained in the tubes until the fibrinous material of which they were composed had become disintegrated. In some examinations there appeared a considerable number of blood-corpuscles; but on every occasion it was noted that there was scarcely any epithelium. On the 25th June it was first observed that some of the casts entangled a few oil-globules, and here and there appeared a cell containing oil. These appearances continued for about three weeks, and occasioned some anxiety lest the kidneys should undergo fatty degeneration. About the middle of July it became evident that the oil was diminishing, and the casts were less numerous, but the albumen was still abundant.

On the 26th July the albumen was reported to be much less, and all trace of the casts had disappeared. The eruption and the dropsy were gone, his appetite and strength had returned, and the pallor of his face had been replaced by a healthy hue. He had been taking steel since the 26th June.

On the 30th July he was improving in every respect, and the urine was *scarcely* albuminous.

On the 1st August he left the hospital without permission, and did not return. The object of his sudden departure, probably, was to indulge his morbid appetite for intoxicating liquids, from which he could scarcely be restrained even while he was in the hospital. It would have been satisfactory to have kept him under observation a few days longer, until the albumen had quite disappeared; but the improvement had been so rapid and continuous, and the quantity of albumen, at the last examination, was so minute, that the case may fairly be considered a cure.

The most remarkable feature in the microscopical characters of the urine in this case, was the peculiar appearance of the casts and their small diameter as compared with that of the large waxy casts to which I have before alluded as occurring in the advanced stages of the chronic desquamative disease. It is evident, that, as the large waxy casts which have the full diameter of the uriniferous tubes must have been moulded in tubes from which the epithelial lining had been previously removed, so the size of the small casts afforded decisive evidence that the tubes from which they had come still retained their epithelial lining. Relying upon this favourable indication, I ventured to suggest to Dr. Budd, when Lewis first came under observation, that his patient would probably recover. My prediction was verified by the result; but I have since discovered that one opinion which I then entertained, and upon which my favourable prognosis in that case was partly based, was, in fact, an erroneous one. I supposed, that the absence of desquamation was an indication that the secreting cells were not involved in the disease; and I inferred, that the blood was in such a morbid state as produced congestion of the Malpighian capillaries, while it affected but slightly, if at all, the epithelium of the kidney.

A reference to the history of the case will show, that the great degree of dropsy, the increased frequency of the epileptic fits, and the other consequences of suppressed renal secretion, cannot be explained on the supposition of mere congestion of the Malpighian capillaries. And, again, the low specific gravity of the urine, which was only 1012, (and this would have been reduced to a lower point by the previous removal of the albumen,) while the quantity did not exceed sixteen ounces in the twenty-four hours, affords decisive evidence of such a deficient excretion, as can be accounted for only by a greatly-impeded action of the secreting cells. Further, the history of Ager's case proves, that a very scanty secretion of urine, attended with rapidly fatal consequences, may be associated with only such a degree of change in the appearance of the secreting cells as suffices to show that they are implicated in the disease, although there has been no desquamation or shedding of epithelium.

A comparison of these cases with those of acute desquamative nephritis leads to the conclusion, that, as the free shedding of epithelium is an efficient means of eliminating abnormal products from the blood, so if, in the case which I first related, the desquamative process had occurred, the disease might have terminated favourably; and, in the last case, that of Lewis, a similar process might have shortened

the duration, and lessened the severity of the attack. It is probable that, in the case of Lewis, the escape from the Malpighian capillaries of the fibrinous materials which formed the waxy casts was a more effectual relief to the circulation than the transudation of serum alone would have been; and there is reason to believe, that actual hæmorrhage would have been still more beneficial. I am convinced, from repeated and careful observations, that the relief thus afforded to the circulation is more than sufficient to compensate for any impediment oft he secretory functions, which may result from some of the tubes being temporarily filled with coagulated blood or fibrin.

The cases of non-desquamative disease to which I have hitherto referred were of an acute character. I will now give some account of the same condition of kidney occurring as a chronic disease. The condition of urine which indicates the existence of the disease in question is commonly as follows:—When first passed, the urine is clear, and either of the natural colour and appearance, or somewhat paler than ordinary. After standing, it deposits no sediment, or merely a slight cloud, composed, perhaps, of pavement epithelium from the bladder. The quantity of urine secreted daily is generally less than normal, and often it is much below the standard of health. The specific gravity varies considerably; it is seldom very low, and often it is up to, or even above, the healthy standard; but the daily discharge of solids by the kidney is almost constantly below the normal amount. The quantity of albumen varies according to the intensity of the disease; but in most cases it is very abundant, so that the urine, when boiled, becomes almost solid. On a microscopical examination, the urine is found to contain neither casts of tubes nor renal epithelium. I have found this to be the case in several instances of the disease. Not unfrequently, however, a careful examination detects some of the small waxy casts which I have before described as found in the urine of Lewis. In some cases, scattered blood corpuscles may be present—but this is not common; and a copious sediment of blood, either in the form of blood-casts of the tubes or otherwise, is still more rare.

The general symptoms which accompany the disease are usually serious in kind and degree. The blood becomes much impoverished by the copious drain of albumen, and at the same time it is poisoned by retained excrement. Dropsy, which is present in almost every case, is often excessive, and very little influenced by any kind of medical treatment. Congestion or inflammation of the lungs or serous membranes, and symptoms referrible to the nervous centres, such as coma and convulsions, are frequent, and often fatal.

The appearances presented by the kidneys are well represented in Dr. Bright's plates (Nos. 2 and 4)—less faithfully by M. Rayer in his illustrations of what he calls the second and third forms of albuminous nephritis, which are, in fact, different stages of the disease we are now considering. The kidneys are usually increased in size and weight, and, as they are firmer and denser than in the normal state, their increase of weight is usually greater than that of their bulk. It is not unusual to find the weight of each kidney as high as 7 or 8 ounces.

The appearances of the kidney, which are most constant and characteristic, are a gradually increasing wax-like pallor of the cortical substance, and a loss of the colour which depends on its vascularity, while the medullary cones retain their vascularity and have a pale pinkish colour. As the disease progresses, the hexagonal lobular divisions gradually become obliterated, until, at length, there remain only a few small isolated vascular patches. The capsule may be readily removed, so as to leave a smooth, ungranulated surface. On a microscopical examination, the greater number of the convoluted tubes present no other change than that of being more opaque than usual, in consequence of an opaque granular condition, and occasionally a brownish yellow colour of their epithelial lining. The epithelial cells appear to contain an unusual quantity of solid matter. The central canal of the tubes is light and clear, not being filled with epithelium, as in cases of the desquamative disease. The canal, however, is sometimes filled with the white coagulable material which forms the small waxy casts; and in these comparatively rare instances of hæmorrhagic spots appearing in the cortical substance, some of the tubes are found to contain blood. The straight tubes of the medullary cones present no change of structure.

When an attempt is made to inject the kidney, it is found that many of the vessels are nearly or quite impervious, so that very little injection can be thrown into them. The condition of the blood-vessels does not differ essentially from that which I have described in connexion with the chronic desquamative disease.

The Malpighian bodies pass through a regular series of changes, from simple engorgement with blood, which appears of a red colour through the unthickened capillary walls, to a gradually increasing thickening and opacity of the vessels, as a result of which they finally assume the appearance of firm, whitish, waxy coils. In this condition, although the vessels appear quite exsanguine, the addition of acetic acid frequently renders their walls transparent, and brings into view a single row of blood-corpuscles in each capillary, the canal of the vessels appearing to be narrowed, while the wall is thickened. In some of the Malpighian tufts, there is no appearance of blood-corpuscles after the addition of acetic acid; the circulation through them had entirely ceased, and, as a consequence of this, the tuft and its investing capsule are shrunk and atrophied, while in other instances oil globules are collected within and upon the vessels.

The walls of the arteries are frequently hypertrophied, but less constantly than in the advanced stages of the chronic desquamative disease. As a general rule, the thickening of the arterial walls appears to bear a direct proportion to the duration of the disease, and an inverse proportion to the general enlargement of the kidney.

The examination of the inter-tubular capillaries gives, for the most part, a negative result. In the advanced stages of the disease, they can rarely be injected, and, when visible at all, their coats appear unthickened, and thus in remarkable contrast with the opaque and thickened Malpighian capillaries. The atrophy and obliteration of the minute branches of the veins are shown by the more or less complete disappearance of the hexagonal lobular divisions on the capsular surface. A microscopical examination detects no appearance of hypertrophy or thickening of their walls. The larger divisions of the veins are sometimes plugged by firm coagula of blood.

It is evident from the foregoing description, that the pale and exsanguine appearance of the cortical substance of the kidney, is partly the result of an actual obliteration of the vessels, and partly of the thickened condition of those which remain pervious, so that their contents are concealed by their opaque walls.

With reference to the increased size and weight of the kidney, there is reason to believe that they are chiefly the result of simple hypertrophy of the glandular tissues, similar to that which occurs when, from any accidental cause, one kidney has to do the work of both; and when, in the discharge of its double function, it acquires a corresponding increase of size and weight.

It must be assumed, that the proximate cause of the disease in question is the admixture with the blood of some morbid products which, not finding a free outlet by the ordinary process of desquamation, tend to embarrass the circulation through the kidney, and, at the same time, they will accumulate in the blood together, with some of the normal constituents of the urine, whose elimination would, of necessity, be retarded simultaneously with that of the morbid materials with which they are associated.

This accumulation of excrementitious materials in the blood will act as a stimulus to the increased growth and development of glandular tissue. For the tissues in question may be said to feed upon the materials for which they have an affinity, and the growth of a gland will be in proportion to the quantity of its proper secretion with which it is supplied by the blood. This appears to be the physiological explanation of the double size of a kidney which has to discharge the functions of two glands, as well as of the increased bulk of the organ which occurs when its secreted products are modified by the admixture of some morbid materials which are difficult of elimination.

It is a point of some interest to ascertain, what is the precise mode in which the bulk of glandular tissue is increased,—whether by the developement of new tubes and Malpighian bodies, or by an increased diameter or length of those which already exist.

There seems no reason to suppose, that new tubes are formed, nor does it appear that an increase in the diameter of the tubes is a common occurrence. One impediment to the last-mentioned change in the tubes is the existence of the fibrous rings of the matrix in which the tubes are

enclosed, and by which they must be constricted when, from any cause, the tubes are distended and dilated. That something of this kind actually occurs in cases of chronic non-desquamative disease, is, I think, nearly certain. The epithelium appears to become more bulky, so as to expand the tubes, which consequently become firmly impacted in the rings of the matrix; and this appears to be one cause of the increased firmness of the kidney which is commonly observed in these cases. It appears, however, that the enlargement of the kidney is insufficiently accounted for by any increase in the diameter of the tubes; and it is in the highest degree probable that there is an actual increase in their length and in the number of their convolutions. It is, of course, quite impossible to dissect out a tube so as to measure its normal length, or the increase which results from hypertrophy. The point in question can be determined only by the method of exclusion,—by ascertaining that there is no other observable condition which will sufficiently account for the existing enlargement of the kidney.

There is an important difference between the hypertrophy of the renal tissues which results from one kidney having to discharge the functions of both, the blood meanwhile containing none but its normal constituents, and those instances of hypertrophy which are occasioned by the urinary constituents being associated with some abnormal products whose elimination is constantly attended with more or less of difficulty. In the first-mentioned instances of hypertrophy, although a temporary embarrassment of circulation and secretion may be occasioned by the sudden assumption of a double duty by one kidney, yet, in process of time, the growth of glandular tissue enables the organ to perform its extra work with ease. The increase in the quantity of renal excrement to be discharged by the single kidney does not, in these cases, exceed a certain definite amount; it is exactly doubled; and this increase of secretory labour is provided for by a corresponding increase of glandular tissue.

But in the instances of enlargement of the kidney, which result not simply from the secretion of a double quantity of the normal urinary constituents, but from a continued effort to eliminate some morbid products, the development of secreting tissue appears to be unequal to the demands which are made upon it. Those abnormal materials whose tardy and difficult elimination have been the original cause of mischief, are constantly present in the blood, and add indefinitely to the strain upon the kidney.

The circulation through the inter-tubular capillaries is retarded in a manner which I can explain only by reference to the slow and incomplete manner in which the gland cells discharge their excretory functions, the serum of the blood is continually poured from the gorged Malpighian capillaries, and the blood-vessels themselves gradually undergo that series of pathological changes which I have already described. Meanwhile, the poisonous excrements, as well the normal as the abnormal constituents, accumulate in the blood and exert a noxious influence upon various parts of the body.

It will be apparent, from what has already been said, that hypertrophy of the secreting tissues is not a constant result of the non-desquamative disease. The conditions which appear to be necessary for such a result are a moderate degree of morbid alteration of the blood, and such a duration of the disease as may suffice for the growth of new tissues. Thus, in an acute case, like that which I referred to at the commencement of my lecture, there could be no growth of glandular tissue in the short period during which the disease continued. On the other hand, the cases in which the hypertrophy of the gland attains the greatest degree, are those in which the changes occur very gradually, so that the growth of secreting tissues nearly keeps pace with the extra work imposed upon it, and is only just insufficient for the complete elimination of the excrementitious materials contained in the blood.

A good instance of this occurred in the case of a man, named George Pow, who died lately in King's College Hospital. He was only 19 years of age, but he had been a great gin-drinker, and at the time of his admission, in October last, he was suffering from ascites, consequent upon cirrhosis of the liver in an advanced stage.

The urine was rather scanty, being, on an average, 26 oz. in 24 hours; its specific gravity ranged from 1010 to 1018; it was moderately albuminous, and frequently tinged with blood, much of which was in the form of tube-casts; no renal epithelium was observed in the urine.

Towards the end of October it was first noted, that his ankles were a little swollen. The swelling gradually increased and extended up the legs and to the scrotum; but the ascites was always the most prominent and distressing dropsical symptom. Meanwhile, he suffered much from dyspnœa, which gradually became more distressing until his death, which occurred rather suddenly on the 27th of November.

The abdomen contained a large quantity of liquid. The liver was very small, contracted, and granular. The spleen was much enlarged. The kidneys were also much enlarged, and both in an equal degree; one weighed 7 oz. The surface was smooth and pale, but with many small hæmorrhagic spots scattered over it. In most parts of the surface, the hexagonal lobular divisions remained distinct. The general appearance of the kidney was not unlike that represented in the 3rd and 4th figures of M. Rayer's 7th plate; but the increase of size and the decrease of vascularity were less than in M. Rayer's case.

On a microscopical examination the tubes and the epithelium presented the appearances which I have before described as characteristic of the non-desquamative condition. There was no evidence of desquamation, or of other morbid change, except in the few tubes which contained blood, and which formed the hæmorrhagic spots before mentioned. The Malpighian capillaries presented the appearances of slight opacity and thickening which are usually observed when there has been a moderate degree of impediment to the renal circulation. There was no evidence of hypertrophy of the arterial tunics.

It would be difficult to ascertain precisely at what time the enlargement of the kidney commenced. It is probable, however, that it had gradually increased during a period of several months before the fatal termination of the case; and it is little less than certain, that it was the result of a beneficial effort to eliminate from the blood some of the noxious excrement with which the gin-drinking habits of the patient were infecting it.

The escape of albumen from the Malpighian bodies was evidence that the growth of glandular tissue was unequal to the demands which were made upon it; the circulation was, therefore impeded, and blood, as well as serum, escaped from the gorged vessels, which had not undergone the degree of thickening that would secure them against rupture.

The pathological changes which I have described as being characteristic of the chronic non-desquamative disease are, in a number of instances, unassociated with any other morbid appearances in the kidney. In a large proportion of cases, however, more or less of fatty degeneration of the renal tissues is found to co-exist with the non-desquamative condition; and it is matter of considerable interest to ascertain the relations which the two forms of disease bear to each other.

A solution of this question is to be sought for—first, by a careful examination of the urine, repeated at intervals, during the progress of renal disease; and, secondly, by an inspection of the pathological appearances presented by the kidneys after death. Each mode of investigation has its peculiar advantages, and both lead to the conclusion, that one form of fatty degeneration of the kidney is a frequent consequence of that non-desquamative disease whose history we have just now been considering.

The appearances in the urine, which indicate the relation and the sequence to which I have referred, are a continuance, for a time, of those conditions which have already been described as characteristic of the non-desquamative disease, viz., a rather scanty secretion of highly albuminous urine, of moderate specific gravity, of nearly the natural colour, usually clear and free from sediment, and containing neither renal epithelium, nor casts of tubes; or, if any of the latter, only those small waxy casts to which I have before referred. After a period, which is very variable in different cases, while the general characters of the urine remain the same, there appears a light, cloudy sediment, which is found to contain some of the small waxy casts, in which are entangled one or more globular or oval cells, enclosing a a variable number of oil globules, some of the cells being completely filled with oil, and presenting the appearance of a dark opaque mass. Some of the casts have adhering to their surface a variable number of scattered oil globules, which have probably escaped from ruptured cells. Some

oil-containing cells and detached oil globules are also scattered over the field of the microscope.

When the disease has terminated fatally, as it too commonly does, the kidneys usually present the appearances which are represented in the 3rd figure of Dr. Bright's 3rd plate; also in the 8th plate of Rayer, in which he has given illustrations of what he calls the fourth form of albuminous nephritis.

The general character of the kidneys, as regards their increased size and weight, their smooth surface, and the pale non-vascular appearance of their cortical substance, are exactly similar to those which have already been described in connexion with the chronic non-desquamative disease. But in the cases now under consideration, there is the addition of certain characteristic granulations, of a yellowish white colour, which are scattered through the cortical substance. These opaque granulations, which have a general resemblance to the, so-called, atheromatous spots in arteries, are found, on a microscopical and chemical examination, to be composed almost entirely of fatty matter; and it is a point of much interest to ascertain the relation which the deposit bears to the normal tissues.

A large proportion of the tubes present, under the microscope, the appearances which I have already described as characteristic of the non-desquamative disease. The epithelium is more opaque and granular than in the natural state, and perhaps occupies a larger space within the tube, so as to produce a slight tendency to dilatation of the tube, and a close impaction within the surrounding rings of fibrous tissue. Occasionally some tubes have their canals filled with the white wax-like material, which, when it escapes with the urine, forms the small waxy casts; and, in other instances, some tubes are filled with blood, in which case hæmorrhagic spots in the cortical substance are visible by the naked eye. The incipient tendency to fatty degeneration is shown by the appearance of oil globules within the epithelial cells of some of the tubes. It is not unusual to see, in the epithelium of a kidney, which, in other respects, appears perfectly healthy, one or more minute oil globules; but, when fatty degeneration is commencing, the oil globules increase in number until, at length, they completely fill the cell. The epithelial cells of these tubes, which are yet in the early stage of fatty degeneration, retain their normal shape and position, forming a single layer on the surface of the basement membrane. As the fatty degeneration advances, the cells assume an entirely different form and appearance, they lose their irregular angular outline, and begin to appear globular or oval with homogeneous transparent walls; but when completely filled, as they often are, with small oil globules, they have a dark and opaque appearance. They have now entirely lost their epithelial character, and cannot be distinguished from the granular cells which are commonly seen in scrofulous or cancerous tumours. One of the yellow granulation, before mentioned, when placed under the microscope, is found to contain these cells in great numbers. A thin section carefully made with Valentin's knife, often shows a considerable length of convoluted tube completely filled and blackened with the opaque granular cells. So that as the hæmorrhagic spots in the cortical substance are composed of convoluted tubes filled with blood, these yellow granulations consist of tubes distended with oil. In many of the granulations it is difficult, and sometimes impossible to trace the continuity of the tubes; they appear to have been ruptured by over-distension, or perhaps they have suffered from atrophy, which would seem to be a necessary consequence of the degeneration of the epithelial cells, and the substitution of the granular oil, containing cells for the normal contents of the tubes. Or it may be, that the degeneration of the cells and the atrophy of the tubes are results of one common cause, viz., the impeded capillary circulation, which precedes and accompanies the changes in question. With reference to this last suggested cause of the phenomena, it is not without interest to remark, that there appears to be an analogy between the small spots of renal degeneration and those patches of degeneration of the muscular fibres of the heart which are associated with a more or less impervious condition of the branches of the coronary artery distributed to the diseased parts. Upon this view of the subject it would appear, that as the spots of renal degeneration are a consequence of obstructed circulation, they afford a kind of evidence of the actual existence of such an impediment. With regard to this point I cannot do better than refer to that section of Dr. Quain's excellent paper, in which he treats of "fatty degeneration connected chiefly with local modification of nutrition."(a)

It frequently happens, that the tubes being ruptured by the knife or other instrument used in preparing the section for examination, the oil globules become irregularly scattered over the specimen, and they often adhere to the fibrous rings of the matrix, so as to give the appearance of this tissue being the actual seat of the fatty deposit. I believe, however, that this appearance is delusive, and explicable, as I have suggested, by the bursting of the tubes and the consequent escape and dispersion of the oil. I have invariably noticed, that while the tubes remain entire, however abundant may be the oil within them, the inter-tubular tissue is free from deposit.

It is rare to find any oil in the Malpighian bodies, except in the form of a few globules in the atrophied capillaries; and even that is a less frequent occurrence in connexion with the form of disease now under consideration, than in cases of the chronic desquamative disease which I described in a former lecture. Oil, in variable quantities, is usually found in the straight tubes of the medullary cones, but this, in all probability, is a result of the lodgment in these tubes of materials which have been washed into them from above. The characteristic granulations rarely occur in the cones, as is at once evident from an inspection of the plates of Bright and Rayer.

That the material which forms the yellow granulations is of a fatty or oily nature is evident—first, from the peculiar and characteristic appearances of the globules when examined by the microscope; and, secondly, from the fact, that the granulations as seen by the naked eye, and the globules visible by the microscope, are entirely removed by digestion in ether. When the fatty matter is in the form of very minute particles, so as to have rather a granular than a vesicular appearance, it will be found that a moderate degree of heat applied to the specimen has the effect of fusing the fatty particles, after which they run together, and form large drops of grease.

The number of fatty granulations is very variable. In some cases there are only a very few scattered through the cortical substance, while in other instances they are thickly disseminated. It will be apparent, from what has already been said, that although, when present, they give a peculiar and characteristic appearance to the kidney, they are, at least in some cases, only a secondary consequence of the non-desquamative disease, which may, and often does, prove fatal without the occurrence of fatty degeneration in any form or degree.

The transition from one condition to the other, as indicated by the appearance of the oily casts in the urine, is one of much significance, and one which, with reference to prognosis, it is of great importance to observe. The non-desquamative condition, which is itself unfavourable for the patient's recovery, as compared with the desquamative diseases, is yet less so than that still greater deviation from the normal state which is indicated by the occurrence of fatty degeneration. I have already mentioned the fact, that during the convalescence from the acute desquamative disease, a small quantity of oil is occasionally seen in the urine, and that in most cases it quickly disappears, together with all other morbid products. We have seen, too, that during an acute non-desquamative attack, as in the case of Lewis, there may be threatenings of fatty degeneration which quickly cease. The most unfavourable cases are those in which, from the commencement of an acute attack, there is a large quantity of oil in the urine; or those in which the long continuance of the non-desquamative disease is succeeded by the signs of fatty degeneration. In such cases, although the duration of the disease may be very variable, the probability of recovery is extremely small, and the prognosis as unfavourable as in an ordinary case of tubercular disease of the lung.

In the cases of fatty degeneration to which I have hitherto referred, the kidneys have been found to contain the fatty matter in the form of characteristic yellow granulations, while the tubes in those portions of the gland which contain no granulations, either have no oil within them, or only very slight traces of it. In a certain proportion of cases fatty degeneration occurs in a somewhat different form, as is evident both from the general appearance of the kidney,

(a) Med. Chir. Trans., Vol. XXXIII., p. 147.

when examined by the unaided eye, and from the results of microscopical examination.

In the cases now referred to, the size and weight of the kidney are usually increased, the colour of the cortical substance is either uniformly pale or mottled by red vascular patches, and occasionally hæmorrhagic spots are scattered over the surface. The medullary cones retain their normal colour and vascularity. The consistence of the kidney is usually softer than natural, and frequently it has an œdematous feel and appearance.

On a microscopical examination, the convoluted tubes are found to be everywhere filled with oil, which has accumulated in their epithelial cells. The oil-globules are usually larger than in the cases of the granular form of fatty degeneration; and the detached epithelial cells, when filled with their oily contents, have a remarkable resemblance to the cells of the liver in the same condition. There is no oil in the inter-tubular tissue, and rarely any in the Malpighian bodies. The tubes of the medullary cones are also free from deposit, except such as appears to have been washed into them from the convoluted tubes. The fatty accumulation, therefore, is confined to the epithelial lining of those portions of the tubes whose office is the secretion of the solid constituents of the urine.

In some of the tubes the epithelial cells cannot be distinguished; they appear to have undergone a process of atrophy, and the tubes are occupied only by their fatty contents. There are none of the yellow granulations, which are characteristic of that form of fatty degeneration before described; the granulations in question being the result, as I have shown, of a fatty accumulation in certain sets of tubes, while the surrounding tubes are nearly or quite free; while, in the instances of what may be called the mottled form of fatty degeneration, the convoluted tubes are almost universally and equally filled with oil.

It is in this form of disease that the greatest amount of fatty matter is found on a chemical analysis. In one well-marked specimen, my friend, Dr. Beale, found, that the cortical substance of the kidney contained, in 100 parts, 79·650 water, and 20·350 solids, and of this solid matter 5·199 (rather more than one-fourth) was fat. In another specimen, I found that the dried solids formed 21·5 per cent.; and of this 3·5 was soluble in ether; so that the proportion of fat was slightly above one-sixth of the solid constituents.

With regard to the symptoms of this form of disease, when the kidneys have been in an advanced stage of degeneration, the condition of the urine and the general symptoms have not usually differed in any respect from those which I have already described in connexion with the granular form of fatty degeneration. The urine is very albuminous, its specific gravity deviating little from the standard of health, and being quite as frequently above 1020 as below that point; for, although the daily discharge of solids may be much reduced, the scanty secretion of liquid, and the large quantity of albumen together, keep up the density of the urine. When first passed, the colour of the urine is generally natural, and, after standing, it deposits only a slight cloudy sediment, in which may be found some small waxy casts entangling scattered oil-globules and oil in cells.

It is probable, that in some cases of this form of degeneration, there may be no appearance of oil in the urine; and there is a difference between the granular and the mottled form of fatty degeneration that would account for this fact. In the granular kidney many of the tubes contain a number of detached oily cells, which may readily be washed out by the stream of liquid flowing through the tubes; while, in the mottled kidney, there is commonly only a single layer of epithelium, which remains adherent to the basement membrane. This condition renders the escape of the cells from the tube scarcely possible, and the only way in which the oil could in these circumstances appear in the urine, is by the rupture of the cells, and the escape of their oily contents,—an event which, I believe, seldom happens, except when fibrinous materials effused from the Malpighian capillaries have coagulated in the tubes. In which case, the fibrinous plug, when it escapes, may carry with it some of the oil from the ruptured cells over which it has passed in its transit through the tube, and so the small waxy casts with oil may appear in the urine.

There is yet another important distinction between the granular and the mottled form of fatty degeneration. In the first-mentioned form of disease the formation of the fatty granulations is preceded, as I have already described, by a non-desquamative disease; this being indicated by the condition of the urine, which is highly albuminous, clear, and without epithelial sediment. On the contrary, the second form of fatty degeneration comes on very gradually and insidiously, and frequently makes great progress before the urine affords any indications of the existence of renal disease. I have occasionally found a large proportion of oil in the renal epithelium after death, in cases which have certainly not been attended by the secretion of albuminous urine. This is the form of disease which Mr. Simon observed in the kidneys of cats, after the animals had been confined for some time in a dark cellar, and which I am told is very common amongst London cats, even when they have not been subjected to the depressing influence of close confinement. Dr. Beale informs me, that he has, at different times, examined the kidneys of nine cats, and that, in every instance he found the tubes distended with oil. The cats had all lived in a brewery, and had been well fed and indolent,—a mode of life which is, of course, very unnatural for a cat.

I at one time believed, that an albuminous condition of the urine, and the other consequences of renal disease, might result from dilatation of the tubes by fatty accumulation within them, and a consequent mechanical impediment of the circulation, occasioned by pressure upon the inter-tubular capillaries. I supposed, that the apparent difference between the effects of fatty accumulation in the liver and in the kidneys,—the former organ suffering little, and the latter, as it appeared, much, from an identical condition of the secreting cells,—might be explained by reference to the anatomical difference between the two organs. The fibrous rings of the matrix, and the capillaries within them, would, as I thought, suffer compression, when, from any cause, the uriniferous tubes were dilated; and in this way the circulation would be impeded, so as to render the urine albuminous. I am still of opinion, that these mechanical conditions must exert a certain amount of influence; but I have long perceived, that I was wrong in attributing to them that great degree of importance which I formerly did.

The history of acute non-desquamative disease has shown us, that a fatal suppression of urine may result from a condition of kidney which is characterized by the almost total absence of any anatomical change in the organ. We have also seen, that a form of fatty degeneration is one of the unessential consequences of the chronic or non-desquamative disease. A consideration of these phenomena, and of the general history of renal diseases, will show the necessity for caution in attributing to morbid structural changes too much influence as causes of any symptoms with which they may have been associated.

It cannot be doubted, that a large and general accumulation of oil in the renal epithelium is a morbid condition, and an evidence of degeneration. But while we recognise the probability, that this degenerated condition of the secreting cells may diminish the functional activity of the organ, and, at the same time, be an efficient cause of further structural changes, we may also perceive the possibility, that the altered appearance of the cells, and the associated impairment of function, may be only consequences of some common cause—of a diminished vital activity, or, it may be, of a loss of the normal relations between the blood and the secreting cells, such as we must suppose to occur in the cases, already referred to, where there is no structural change in the kidney sufficient to explain the suspension of its functions.

At the commencement of my first lecture, I spoke of the benefit which renal pathology derives from the light which Mr. Bowman has thrown upon the anatomy and physiology of the kidney; and here it may not be out of place to remark, that the study of renal diseases is greatly facilitated by the fact, that the morbid deposits or accumulations to which the kidney is liable, occur, almost without exception, in such a situation within the uriniferous tubes, that portions of these materials are continually washed out by the stream of liquid which is poured into the extremities of the tubes, so as to come within the sphere of our daily observation.

We have thus an opportunity of ascertaining the nature, and tracing the progress, of renal diseases, which we do not possess in the case of any other internal organ. Hence arises the probability, that renal pathology and diagnosis will soon attain to that degree of accuracy which already characterises the anatomy and physiology of the kidney.

ORIGINAL COMMUNICATIONS.

DYSMENORRHŒA.

By EDWARD RIGBY, M.D., etc.

Senior Physician in the General Lying-in Hospital; Examiner in Midwifery in the University of London.

[Continued from p. 128.]

Miss H., aged 27, diminutive, feeble. Has been under treatment in the country for dysmenorrhœa, leucorrhœa, and, apparently, ovarian irritation, attended with much gastric derangement.

December 16, 1850.—The last catamenia were more copious than usual, and she felt proportionally relieved by the discharge. She remains free from suffering until the halfway period, and then has continued pain in the groins, extending to the loins and sacrum, with occasional darting pains through the pelvis. Pulse feeble, bowels costive, urine high-coloured; the passage of solid fæces produces pain; the abdomen just now is flat, but occasionally is much distended with flatus.

℞ Pil. hydrarg. gr. v., alt. noct.

℞ Potassæ bicarb. ℈iv., potassæ nitratis ℈ij., sp. ætheris nit. ʒss., aquæ menthæ pip. ʒvijss. M., ft. mistura, cujus sumat cochl. magn. ij. bis die post cibum.

℞ Ferri sulph. gr. ij., magnesiæ sulph. ʒi., acidi sulph. dil. ♏viii., aquæ menthæ pip. ʒi. M., ft. haustus primo mane sumendus.

21th.—Feels and looks much better. Bowels well opened once or twice daily; more healthy; urine still high coloured; tongue clean. The halfway time arrived on the 21st; she had the ovarian pain and pain of back all day, but it went off towards night, and has not returned; no flushing or pain of head; sleeps better.

℞ Acidi hydrochlor. dil., acidi nitrici dil., aa. ʒi., liq. taraxaci ʒi., infusi gentianæ co. ad. ʒviij. M., ft. mistura, cujus sumat cochl. magna ij. bis die ante cibum. Rep. pil. semel in septim. Rep. haust. ferri et magnesiæ sulph. primo mane.

January 20, 1851.—The period came nearly at the right time; the discharge was natural and attended with very little pain. Pain returned six days ago in the groins, loins, and lower part of abdomen, occasionally of a darting character, and has increased since; the bowels have been very well opened, but are offensive; tongue clean; pulse natural; urine thick; has had hæmorrhoidal throbbing for the last two or three days; has had a slight degree of leucorrhœa for two days.

Mist. ferri citratis effervescens bis die. Rep. mist. potassæ bicarb post prandium. Rep. mist. ferri et magnes. sulph. o. m.

March 31.—Has improved considerably in health; the last catamenial discharge came exactly at the right time, and without pains. Ten days ago she had an attack of rheumatic gout, during which the ankle swelled; since which she has suffered much shooting pain of the right eye, which is red, and waters a good deal; she has also pain of left shoulder. The bowels are offensive, although she has been taking blue pill occasionally.

℞ Hyd. chloridi, ext. aloes aquosæ, ext. colchici acet., pulv. ipecacuanhæ, aa. gr. j. M., ft. pil. j.; sumat j. alternis horis per duas vel tres vices.

℞ Potassæ bicarb. ℈iv., potassæ nitratis ℈ij., vini colchici ʒij., aquæ menthæ pip. ad ʒviij. M., ft. mist., cujus sumat cochl. magn. ij. bis terve die.

April 3.—Bowels opened five times since taking the pills; much scybala came away at first; the last evacuation contained plenty of yellow bile; urine clear, but high coloured; she had some pain last night across the pubes; the pain of right shoulder continues, but the pain of eye is gone; appetite better.

Rep. pil. et mist.

This is a well marked case of uterine and ovarian irritation, arising from intestinal derangement in a feeble system, attended with severe dysmenorrhœal suffering. It commenced at the half-way period, and continued until the menstrual discharge relieved her. From the severity of the pain in the ovarian regions, and the pain produced by the passage of solid fæces, we may presume that a considerable amount of ovarian irritation existed.

After a week of alterative and laxative medicines, a decided improvement was perceptible. The complexion had lost its unhealthy tinge; she felt brighter and less depressed; the secretions had improved, and, although the pain came on as usual at the half-way period, it went off again after a few hours, and the catamenia appeared at the right time, and in a natural manner.

The next attack of pain was a week earlier than usual, and lasted longer. The general health had improved, but there were still evidences of gastric derangement; and to this circumstance I think must be attributed the greater amount of pain,—the hæmorrhoidal congestion and slight leucorrhœa which occurred at this time. As this state appeared to be in great measure depending on the feeble state of the system, I decided on giving her a more powerful tonic, in the form of steel, which she was scarcely in a condition to bear in the first instance. The attack of rheumatic gout which followed, may probably be attributed to the increased power of the system thus obtained, for she had greatly improved in general health, and the last catamenial period had been quite natural, and without pain. I therefore gave her a combination of calomel, ipecacuanha, acetous extract of colchicum, and aloes, which was much recommended by the late Mr. Anthony White, and which certainly exerts a most powerful action on the liver, and produces great relief in gouty or rheumatic gouty attacks connected with gastro-bilious derangement. A large quantity of scybala came away, followed by a copious flow of yellow bile, and marked relief. The weather soon allowed her to take regular exercise, and thus to establish that activity of the various excreting organs upon which health so mainly depends.

Miss L. H., aged 15, pale, stout, feeble.

Feb. 17, 1851.—Pulse very weak; tongue pale and furred; bowels confined, evacuations dark; flatulence; urine thick; does not perspire easily.

Complains of severe suffering at the catamenial periods, which are preceded for two days by intense frontal headache, extending down the right side of nose. Much pain across the pubes when the discharge comes on; this pain lasts four days; the discharge, which is attended with a few clots, and is rather copious, lasts six. She has a good deal of pain in the loins and breasts at these times, which are also usually attended with a catarrhal attack.

℞ Pil. hydr. extr., coloc. co., extr. hyose., aa. ℈j. M. ft. pil. xij.; sumat. ij. h. s.

℞ Acidi hydrochlor. dil. acidi nitrici dil. aa. ʒj., liq. taraxaci ʒj., infusi aurantii co. ʒvij. M. ft. mistura, cujus sumat cochl. magna ij. bis die ante cibum.

℞ Sodæ potassio-tart. ʒiss. omni mane ex aquâ.

April 1.—Has had influenza; is looking clearer; pulse feeble; headache rather better; catamenia appeared on the 9th March; the precursory pain was decidedly less, but the discharge was more copious, and with a few clots; had a good deal of mammary pain, aching of limbs, &c., during the attack of influenza.

℞ Pil. hydr. gr. iij., ferri sulph. gr. ij., extr. coloc. co. gr. v. M. ft. pil. ij. h. s. s.

April 26.—Looking better and clearer; feels better; pulse stronger; tongue cleaner; bowels regular; catamenia appeared on the 18th, viz., after an interval of nearly six weeks, preceded by very little headache and less pelvic pain than usual; she had a good deal of mammary pain; the discharge was more free at first, but there was a larger amount of clots than before.

Rep. pil. p. r. n. ℞ Potassæ bicarb. ℈iv., potassæ nitratis ℈ij., sp. ammoniæ arom. ʒiiss., vini colchici ʒiss, aquæ menthæ pip. ʒviiss. M. ft. mistura; sumat cochl. magn. ij. bis die post cibum.

May 27.—Catamenia appeared on the 19th; the period passed over more naturally than she ever remembers. Looking better and feels much stronger; bowels moved two or three times daily; there is a good secretion of healthy bile. Is going shortly to Italy.

This patient belongs to a large family, several of whom, from living in luxury and indolence, have grown up to be delicate, and two have suffered severely from attacks of rheumatic gout and acute rheumatism. The unhealthy state of the bowels and urine, and the almost entire absence of cutaneous secretion, the intense frontal headache, just before the period, extending down the right side of the face, evidently of neuralgic character, and the febrile catarrhal attacks which usually came on at these times,

show that she also was more or less predisposed to similar affections.

Besides the ordinary alterative and tonic medicines which would be indicated in such a case, I thought it desirable to clear the bowels every morning with a dose of the Rochelle salt, so well known for its mild laxative action, and for its efficacy in relieving an acid and loaded state of the urine. Her appearance improved, and the next period was attended with decidedly less pain, although, under the name of influenza, she had what I presume was the catarrhal attack which usually accompanied these times. The precursory headache was not much diminished in severity. The next period, however, showed a considerable improvement in all her symptoms with the exception of a larger amount of coagula in the catamenia. Feeling strongly inclined to attribute this condition of the catamenia to the diathesis which I have already alluded to, the more so as two of her family had suffered severely from acute rheumatism and rheumatic gout, I determined, now that the secretions were better and the strength had improved, to try the effect of alkalies with small doses of colchicum, repeating the blue pill occasionally.

This treatment answered well; the next period was more natural than she had ever known it to be. The secretions were natural, and the general improvement of health and strength well marked.

OBSERVATIONS

ON THAT PORTION OF THE

"SECOND REPORT ON QUARANTINE," BY THE GENERAL BOARD OF HEALTH

WHICH RELATES TO THE YELLOW FEVER EPIDEMY ON BOARD H. M. S. ECLAIR, AND AT BOA VISTA IN THE CAPE DE VERDE ISLANDS.

By J. O. M'WILLIAM, M.D., F.R.S., R.N.,
Medical Inspector H. M. Customs.

[Concluded from page 515.]

Let us see how far this statement is borne out by the facts of the case.

Joana Texeira, who lived in the same room with Anna Gallinha, was seized with fever three days after Gallinha's death. In five days more her son was attacked. (Dr. M'William's Report, pp. 28, 9.) Maria Nazarinha, another visiter of Gallinha's, died during Texeira's illness. Manoel Affonso, who was seen in Gallinha's house, (although denied by his widow,) and who lived near to her, was attacked the day after Gallinha died. (Dr. M'William's Report, p. 26.) Gertrude Bent, who had visited both Gallinha and Manoel Affonso during their illness, was attacked the day after Affonso's death. (Dr. M'William's Report, pp. 27, 28.)

The links of the chain could easily be extended to greater length, both from Anna Gallinha and Manoel Affonso.(a)

It would have been much more correct had the "Report on Quarantine," instead of saying that the chain of evidence "here snapped," had stated, "here Dr. King's investigations, as regards Porto Sal Rey, are at an end."(a)

With regard to the outbreak of the epidemy at Rabil, the first case, that of Lonis Pathi, is thus spoken of in the "Report on Quarantine":—"It will scarcely be considered as affording an additional link, since, admitting that this man contracted his fever while employed on board the Eclair, his case would be merely one of infection from going on board a foul ship," etc. "But as in the locality of the dwelling of Gallinha, so in the district in which this man lived, there were local causes abundantly sufficient to account for the endemic origin of the disease." ("Report on Quarantine," p. 104.)

It will be remembered by those who have examined the Reports of the Boa Vista fever, that Pathi was taken ill at Moradinha, where he remained eight days, and was then conveyed to his house in Rabil, where, I am of opinion, he arrived about the 25th September, and that one of his daughters was first seized in the beginning of October; the rest of his children and his wife were attacked in succession, all much within a reasonable incubative period.(b) I need scarcely add, that the evidence as to Pathi's being the first case at Rabil is overwhelming.(c)

The "Report on Quarantine," with reference to Pathi's case, continues:—"It is also to be particularly observed, that a child in another family at Rabil, having no communication with the family of Pathi, died about the same time as Pathi's first child," &c.—(Report on Quarantine, p. 101.)

This statement is made, I presume, on the strength of a reply to a question (1327) put to José Marques; but the evidence of Joaquim Pathi (751), the cousin of Luis Pathi, (more likely to remember events in Luis Pathi's family than Marques,) goes to show, that Pathi's children were the first that were taken ill at Cabecada. But, even supposing that Manoel Fachina's child was the first case of death, it must be recollected, that he lived next door to Luis Pathi, in whose house, by Fachina's own evidence, his wife had been a frequent visiter during Pathi's illness. So much for this alleged "non-communication."

(a) The following clear and well arranged Tables, showing the results of the inquiry at Porto Sal Rey, are taken from the *British and Foreign Medico-Chirurgical Review*, Vol. I., p. 56:—

TABLE, No. 1.—Names of Persons living in the Houses in the Beira Row, Pao de Varella, adjacent to that in which the Soldiers were living. There are only four houses in the Row:—

Theresa Maria Jesus, next door above.
Anna Gallinha, and Anna Terceira, next door below.
Jose Lishoa, next door to Anna Gallinha.
Manuel Affonso, twenty yards away.
Gertrude Bent, next door to Manoel Affonso.

TABLE, No. 2.—Names of those taken ill first in Porto Sal Rey, with the Dates, as far as they can be ascertained. Those marked thus * fatal:—

*Anna Gallinha, October 12th.
Anna Texeira, October 19th.
*Manoel Affonso, October 17th.
*Maria Nazarinha, between October 20th and 25th.
Theresa Maria Jesus, between October 19th and 24th.
*Gertrude Bent, October 21st.
*Antonio Perica, October 20th or 21st.
Lishoa, October 21st.

TABLE, No. 3.—The names marked thus,* are those of persons attacked with fever after the intercourse referred to, within the incubative period:—

. Persons most in contact with Miguel Barbosa and Pedro Manoel:—*Anna Gallinha, who cooked for them; *Sylvester Rorness, whose wife also washed for them; *Anna Texeira, who visited them often.

2. Persons most in contact with Anna Gallinha.—*Anna Texeira, who nursed her: *Manoel Affonso, *Gertrude Bent, *Maria Nazarinha, often in the house; *Lishoa, lived in the next room; Piedad Angelica.

3. Persons most in contact with Anna Texeira:—Dr. Kenny, not taken ill for sometime afterwards; *Her son, who nursed her; *Theresa Maria Jesus.

4. Persons most in contact with Manoel Affonso:—*Luis Ignes, visited him often; *Antonio Perica, who carried the corpse to Rabil; *Gertrude Bent; *the wife of Joachim das Neves.

5. Persons in contact with Sylvester Romess:—*His child, niece, and wife.

6. Persons in contact with Antonio Perica:—*His wife; *Eusebio da Luz, who nursed him; *a girl in the house.

7. Persons in contact with Lishoa:—*A son of Senhor Carvahal, who was two nights with him.

"If our readers will now glance over the names contained in these three Tables, they will find that each is almost a copy of the others, and they will find that the proof is complete, that certain persons, living nearest and most in contact with the two soldiers, were first attacked. This is a fact, and is independent of all explanation or hypothesis of contagion."—*British and Foreign Medico-Chirurgical Review*, Vol. I., p. 57.

(a) "With regard to the future spread of the disease in Porto Sal Rey, Dr. King is silent; he does not allude to any cases subsequent to that of Anna Gallinha."—*British and Foreign Medico-Chirurgical Review*, No. 3, p. 167.

(b) Dr. King states, that the children were not taken ill until a month after the father's return home. I must here observe, with reference to this or to any other difference between Dr. King and myself, as regards the epidemy, that I beg to refer to the answers given to my questions, which are set down in detail. Dr. King's Report contains no such means of reference; and I must leave it for others to decide whether the mode of inquiry pursued by Dr. King at Boa Vista, or that adopted by myself, was best calculated to elicit truth from the interrogated, or to convey the real facts of the case to others. Dr. King's method of inquiry is to be found at p. 4 of his Report.

(c) "The following are the names of the owners of the houses immediately adjacent to Luis Pathi:—Manoel Fachina, Joaquim Marques, Joaquim Pathi, Manoel Rosa Luis Delgado Nazario.

"The following are the names of those first attacked in Rabil, with the dates, as far as they can be ascertained:—

"1. Luis Pathi—Sept. 18th. [Moradinha, J. O. M'W.]

"2. Wife of Manoel Fachina—soon after the return of Luis Pathi to his own house, viz., the 26th or 28th September. She had been a good deal in the house of Luis Pathi.

"3. Child of Manoel Fachina—very soon after the mother. This child died about the same time as Luis Pathi's child, or, according to some evidence, before.

"4. Two children of Luis Pathi—4th and 11th October.

"5. Manoel Marques—very early in October.

"6. Joaquim Marques—between the 8th and 12th October.

"7. Joaquim Pathi—about this time.

"8. Family of Joaquim Pathi—soon after the father.

"9. Manoel Rosa—immediately after Joaquim Pathi.

"10. Child of Manoel Rosa—two days after her father's attack.

"11. Luis Nazario—two or three days afterwards."—*British and Foreign Medico-Chirurgical Review*, Vol. I., pp. 57, 58.

It seems scarcely necessary here to follow out the Fever in its course to the other villages. In my Report, it will be found, that its origin at each village is traced to contagious importation. This I always ascertained by going from house to house, and personally examining the inhabitants.

I must claim for my Report, in all cases of supposed difference between Dr. King and myself, the probability, at least, of much greater accuracy as to events and dates than that of Dr. King; for my conclusions were founded on the examination of many persons on the spot, nay, in the very houses where the fever first appeared, and in those to which the fever afterwards spread, in each village.

This does not seem to have been done by Dr. King; as, for instance, he seems to have relied almost exclusively, if not entirely, upon the evidence of the Judge at Fundo das Figueiras, for his information regarding the whole three eastern villages, Cabeca dos Tharafes,—Fundo das Figueiras,—and Joao Gallego.

With regard to Cabeca dos Tharafes,—the most important, in this inquiry, of the three villages, inasmuch as it was the first in which fever appeared in that part of the island,—I have good reason to believe, that Dr. King did not once enter this village. Then, as respects Porto Sal Rey, the mode in which Dr. King obtained his evidence there was chiefly, if not wholly, thus:—His list of queries were written down, and John Jamieson, the Consul's storekeeper, alone went the round of the houses, getting answers to those queries in the best manner he could, and then brought them to Dr. King, who transcribed them, thus obtained, into his own journal, or note-book.(a)

This was not my mode of investigating the facts of the epidemy. I found John Jamieson a very useful and willing assistant in all my journeys and inquiries; but I myself was present at the examination of each person, and put the questions and received the answers myself.

I should not have taken this notice of Dr. King's method of investigation, had I not felt compelled to do so, from the evidence I procured having been alleged, in the "Quarantine Report," to be "loosely taken," &c.; while the "details" of Dr. King are stated to be "most circumstantial." I feel necessitated to defend my own Report, when unfairly assailed, and to show the real value of the "set-off" attempted to be brought against it.

In the "Report on Quarantine," it appears to be assumed, that, to prove the contagiousness of a disease, all persons exposed to the supposed source of contagion, whether directly, by intercourse with the sick, or indirectly, by communication with those who, although visiting the sick, continue in good health, ought to be infected.

A very slight acquaintance with medical etiology would have suggested, that the laws of contagion involve no such necessity. It is in accordance with those laws that the greater number of those exposed to morbific influences escape, and that some of those chiefly in contact suffer. "To insure," says Professor Simpson, "in any instance, invariability of antecedence and consequence among physical, metaphysical, and vital phenomena, the circumstances under which the causes are applied must be, at all times, in all necessary points, perfectly similar." Moreover, before the body can be rendered susceptible of a contagious or any other morbific influence, it must be so far altered from the standard of perfect health as to constitute that particular, although unknown, state which is called "predisposition." It is well known, that physicians and others constantly visit patients labouring under notoriously contagious diseases, but nevertheless escape. Or they may escape nine times, yet be infected on the tenth.

From want of attention to these simple but well-established facts, and from not duly considering the particular circumstances of each case, we find that, throughout that part of the "Report on Quarantine" which treats of the Boa Vista epidemy, it seems to be a matter of wonder how, if the disease in the Eclair was contagious, it was not introduced into the town by the crew, who got leave shortly after the ship's arrival; why the women who washed the foul linen escaped until after the fever was general in Porto Sal Rey; why Captain Estcourt did not infect the family of Mr. Macaulay; why the officers of the Eclair and their servants, who lived in the house at Santa Barbara, did not communicate the disease to the people of that house, or to that of the town; why Dr. Kenny, Dr. Almeida, and John Jamieson, did not carry the infection with them to their respective homes; why the soldiers Perez and others did not at once infect the barracks; why the labourers aboard the Eclair and at the coal heap, and their families, did not earlier suffer from the disease; why the Governor-General and his suite, who fled to the other islands, not only all escaped, but failed to infect any others in those islands, etc.

Facts are wanting to establish with absolute certainty, although we are far from being in a position to deny, the transmissibility of yellow fever through the medium of fomites. All, however, will admit, that this mode of the propagation of any disorder capable of being propagated from the sick to the healthy, is far less powerful than that arising from direct intercourse with sick persons.

Now, it has never been alleged,—in fact, it is in the highest degree improbable,—that any of the petty officers, or of the few seamen who got leave, were otherwise than in good health, or were not, at all events, as well as men could be after service on the West Coast. With respect to the washerwomen, the clothes washed by them belonged to the officers. Now, no officer, with the exception of two, (the gunner and a master's assistant, who were placed on the sick list for fever on the 1st August, and discharged to duty, the one on the 13th and the other on the 19th of the same month) had been the subject of fever from its outbreak up to the period of the arrival of the Eclair at Boa Vista. In the Admiralty Correspondence (page 28) it is, moreover, stated, (and, by the way, is not noticed in the "Report on Quarantine,") that the bedding and clothes of all deceased persons were thrown overboard. The washerwomen, therefore, could have washed the clothes belonging to two persons only who had suffered from fever, but none belonging to those who had died.(a)

As respects Captain Estcourt, after he went to Mr. Macaulay's house, he observed the greatest precautions after his visits to the fort, carefully washing himself and changing every article of clothing before seeing any member of his family. He became a guest of Mr. Macaulay on the 25th of August, and Mr. Macaulay and his family left Porto Sal Rey for the north side of the island, on the 4th of September, and did not return until the 27th of that month; so that, during one-half of Captain Estcourt's sojourn at Porto Sal Rey, the only persons with him in Mr. Macaulay's house were the black servants.

As regards the officers and their servants, the house in which they lived was entirely given up to them, and occupied by them exclusively. They were sent to the fort in accordance with a rule of Captain Estcourt's, rigorously carried out, not only as regarded the officers and the crew, but likewise himself. Mr. Macaulay, in a letter to me, dated at San Nicolas, March 30, 1846, says, on this head:—"Dr. Stewart states, at page 5,(b) some of the officers and their servants were attacked with fever while in the town; the Captain was taken ill while living in the town in the house of an English family. The purser lived in the house of another English gentleman when taken ill, and remained there until the day before his death."

"The above passage," observes Mr. Macaulay, "conveys a very erroneous impression. The rule laid down by Captain Estcourt, *and strictly followed in every instance*, was, that, if any of the officers or servants living in the town were taken ill, they should be *immediately* conveyed to the hospital on the small island. I was present on the occasion when one of the Eclair's lieutenants came to request of Captain Estcourt that a brother officer who felt unwell might be allowed to remain, at least for a short time, at the officers' quarters in the town, until it could be ascertained whether he had fever or not, as it was hoped that a dose of medicine would set him to rights. Captain Estcourt refused to comply with the request, stating, that he should require all his officers to follow the same course which he should observe himself, and to remove to the hospital at the fort, as soon as any symptoms of illness was felt. This was the conduct actually pursued by Captain Estcourt when he as attacked a short time afterwards."

The intercourse between John Jamieson and the Consul's family was restricted as much as possible, and Dr. Kenny lived in a house by himself. The family of Dr. Almeida was

(a) I have received this information from John Jamieson himself, a man whose word I never had reason to doubt.

(a) I have since ascertained, that the Gunner's clothes were not taken ashore. Those who know anything of men-of-war, are aware that the clothes of the crew are washed and scrubbed on board.

(b) Manuscript Report.

at this time chiefly at Boa Esperanza, about two miles from Porto Sal Rey; and he visited the fort once only while the sick were there, or twice at the very outside.

It never has been alleged, that Georgio or the two prostitutes Anna Gaspar and Rozina St. Antao, were infected by the crew of the Eclair. The headache and other symptoms, mentioned by Georgio, constituting as they did part of his evidence, were noticed in my Reports, as statements arising out of the inquiry, but not as matters of importance.

Athanasio Perez was relieved from his guard at once when he was taken ill at the barracks. Pedro Manoel, of the same guard was not sick, until the fever was general in the town, in which there is nothing very extraordinary: and Antonio dos Santos, also of this guard, was not taken ill until three weeks after his return from the fort. The non-infection of the soldiers at the barracks by the disease proves nothing further, than that, from those cases, or from the case of Manoel Antonio Alves, who was four or five days ill in the room behind the barracks, the disease was not communicated,—a circumstance by no means uncommon in the history of contagious disorders, and constituting a mere negative fact of little moment in an epidemy, which furnishes abundant instances of positive contagious propagation. (a).

It is judged, in the "Report on Quarantine," that the fever, if contagious, ought to have been communicated to the labourers employed on board the Eclair, in the launches, and at the coal-heap, and by them to have been conveyed to their families at a much earlier period.

The answer to this is obvious. No labourer, with the exception of Portajo, the slave who died, ever was within the walls of the fort while the sick were there, although the coal-heap labourers mixed with the healthy portion of the crew; but many of them (Luis Pathi among the rest) were on board the Eclair the day on which the sick were re-embarked.

As most, if not all, of the labourers were at one time or another on board the Eclair, I might, with much greater reason, ask, How did they escape from the effects of the dreadful malaria alleged to have existed in the hold? The labourers, at all events a large portion of them, were continually being exposed to this supposed source of miasmatic poison; but they were not within the sphere of contagion from the sick until the last.

The soldiers of the guard, on the other hand, were all the while more or less in direct intercourse with the sick at the fort, and accordingly we find among them the first attacks and the first deaths at Boa Vista.

Nor, as has been said before, is it at all necessary, as is assumed in the "Report on Quarantine," that "to prove the spread of a pestilence by contagion, communication, either direct or indirect, must be proved to have existed between all the persons attacked." ("Report on Quarantine," p. 104.)

If the first cases of yellow fever, or of any other disorder, appearing in any town or locality, are distinctly traced to a contagious source, we have no right to deny, although we may not be able to prove communication in *every* case, that the spread of such disorder is due to the same cause. If the disease be admitted to be contagious in the first cases, *à fortiori*, it must also be presumed to be so in all the other cases, although we may not be able to connect every link of the chain of propagation. Our failure to establish such an unbroken chain in all the cases occurring from the beginning to the end of an epidemy, would not show the want of a contagious cause throughout, but rather our want of success in discovering it in every such case.

"The Report on Quarantine," p. 96, observes—"According to the view of Dr. M'William, therefore, this disease must have been of a very singular character, for in its origin at Shebar it was not contagious, at Boa Vista it became contagious, while in the other islands of the Archipelago, wherever the sick and the uninfected fled, it again laid aside its contagious character, and did not spread to a single individual."

This is not the place to discuss the question of a disease primarily not contagious, having the property of contagion impressed upon it by contingent circumstances; but it has been generally allowed, that the history of the events of the Eclair greatly favour this view. But the statement, that it laid aside its contagious qualities afterwards, demands special attention, as it rests upon no grounds whatever.

I assert, without fear of contradiction, that with one very notable exception that came to my knowledge long after my "Report" and "Remarks" were written, among all those who fled from Boa Vista, it cannot be shown that any sick persons landed at any of the other islands. Those who fled from the island were people of the better class, and while at Boa Vista adopted precautions against infection. This was the case with the Governor-General, Mr. Macaulay, the Collector of Customs, and others who left the island after the fever had well broken out. The Governor-General, in his letter, distinctly states, "not one of those who emigrated to the different islands of the Archipelago *had the disease, or communicated it to others.*" Where did the authors of the "Quarantine Report" learn that any "*sick*" fled to the other islands?

"When," says Mr. George Miller, "the ship that conveyed the Governor-General and his suite to Brava, was entering the harbour of that island, one of His Excellency's servants was found to be suffering from the fever. The dismay and confusion at this discovery were great; but it was quickly resolved upon that the servant should be landed and placed in a cavern at some distance to leeward of the landing place, and there kept in strict quarantine. The sequel is this: the poor man died, all his things were burned, and the body was, with the observance of great caution, buried. The disease was not communicated to the shore; and the Governor now issued a Portaria, declaring Boa Vista infected, and subject to the most stringent quarantine regulations; and most rigorously were they enforced."

I found it impossible to arrive with any degree of certainty at the correct amount of the population of Boa Vista not attacked. As an approximation to the truth, I supposed that a third of the whole probably escaped. But we know, without doubt, that, with the exception spoken of, Don José di Norronha and his suite, consisting of sixty persons,(a) Mr. Macaulay and his family, Mr. Pettingall and his family, the Consul and his family, Mr. Martines and his family, who left the island, all escaped, except those that afterwards returned and had intercourse with sick persons. If we add to these, Dr. Almeida's family and servants, and those who segregated themselves at Espinguera, at Cantor, and at Agua dos Caballos, we have, on the most moderate computation, 250 persons, among them upwards of fifty Europeans, who adopted precautionary measures, and all escaped.

Now, I will put it to any unprejudiced person, whether favourable or unfavourable to the doctrine of contagion, how, supposing the disease to have depended upon a cause existing in the general atmosphere, Don José, his suite, and all the other families, could by any means escape? Can it be believed, that not one, even among the Europeans, was susceptible of this alleged generally pervading influence?

Judging from all experience of the action of miasmatic poisons, the escape of so many persons is inexplicable, on the assumption of the disease having been owing to a virus floating in the general atmosphere. But their immunity can be rationally accounted for, under the precautionary circumstances stated, on the ground of the propagation of the

(a) An attempt is made, in a note (pp. 306 to 317) appended to the "Report on Quarantine," to damage the value of the evidence, because Miguel Barbosa stated that Luis Briza was sick in barracks when he was, and as Briza died on the 12th November, he was ill about thirty-six days. No notice, however, is taken of the evidence of Corporal da Cruz Silva, in which he says, that "he thinks Luis Priza was not taken ill until the fever was general in the town." Corporal Silva belonged to the same guard with Briza. And as Briza did not die until November 12th, the probability is that the corporal was right, rather than Barbosa, who was himself ill at the period of which he spoke. Then there are also objections, because the soldiers of the guard did not earlier infect the barracks; because there is no proof that Luis Pathi assisted to hoist the sick in, although he was on board when the sick came from the fort; because one man—the slave of Senhor Nicolas Tavares—disputes the claim of Chico Fernandez having been the first case at Estacia, in opposition to the evidence of Senhor Tavares himself—a most intelligent man, and to that of Chico's sister, Libania; because it is doubtful whether Dr. Almeida visited the fort once or twice. These and other comparatively insignificant circumstances are dilated upon at length, and apparently with great self-satisfaction on the part of the writer. But the note throughout is indicative of a desire, it may be of a capacity, limited to carp at the occasional discrepancies to be found in the evidence—to deal, in short, only with the minor and unimportant details and not with those main and leading facts of the case which serve to guide the judgment in the elimination of the truth from any amount of evidence submitted to it.

(a) In my "Report" there is a mistake (whether owing to an error in the manuscript Report, or to a typographical error I cannot say) concerning the suite of the Governor-General. It is stated, that the "suite" consisted of sixty Europeans. This was not the case. There were sixty persons, but by far the greater number were natives of the islands, and the remainder were Europeans.

disease having been dependent upon intercourse with the sick.

The opinion of the Governor-General, as expressed in a letter that appeared in the *Gibraltar Chronicle*, attributing to the fever at Boa Vista an endemic origin, is very prominently paraded in the "Report on Quarantine." His Excellency's letter to Dr. King, an extract from which is given in my "Remarks on Dr. King's Report," p. 10, telling him that no such disease as that which devastated Boa Vista was ever known in those islands before the arrival of the Eclair, and that "the fevers which have a local or indigenous origin, are called by the doctors *miasmaticas*," is passed by in silence in the "Report on Quarantine." In a letter to me, dated Jan. 8, 1848, (also to be found in my "Remarks," p. 10,) His Excellency says: "You here see I have changed my first opinion. I am quite convinced that the fever was contagious, and that it was introduced into Boa Vista by Her Britannic Majesty's ship Eclair." Long before His Excellency wrote to Dr. King, he stated (in a letter to Mr. George Miller), "I am convinced the fever was contagious from its commencement, and during its progress over the island."

These statements, of which the authors must have been fully cognizant, are never alluded to in the "Report on Quarantine."

Nor is there in the "Report on Quarantine" the slightest notice taken of the well-established instances of exemption from fever procured during its prevalence at Boa Vista by isolation and segregation of healthy individuals from infected districts, which are detailed in my "Report," pp. 107, 108, and in my "Remarks," p. 10. "At *Espingueira*, near Mount Broyal, *at Cantor*, near Mount Ochello, and at *Agua dos Caballos*, situated little more than a mile from Cabeca dos Tharafes, I saw so late as May, 1846, little colonies, amounting in all to fifty-seven persons, who, in the early part of the epidemy, had fled from Joao Gallego, and other villages, and cut off all communication with them. Not one that remained was attacked."(a)

I would ask,—Is the omission of all notice of these statements dealing fairly with the question? There surely appears in such a mode of procedure a one-sidedness more becoming a reckless crusade against Quarantine and contagion, than a philosophical and impartial search after truth.

In a note appended to the "Report on Quarantine," pp. 237, 238, there is an extract from Dr. King's "Report," in which, after speaking of the murrain among the cattle, it is stated, that "there was this remarkable coincidence,—that after an interval of *some months*, and the disappearance of the disease both in man and beast, the same fever broke out again in the towns and villages about the rainy season."

Dr. King has not supplied us with the facts upon which he built this statement; but I am in a position to prove, that the first case after I left the island occurred on the 19th or 20th July, 1846, in a person well supplied with the necessaries of life, in one of the largest, cleanest, and best-ventilated houses in the town. Recovery took place after extreme peril. The next case was a respectable salt-merchant, who also lived in a good house, and had visited the first case. The third case was also a salt-merchant in good circumstances, and living in a good part of the town. I could multiply the cases if necessary. I shall only add, that communication with sick persons was in each case proved, and that the two last-mentioned cases died during the illness of the first. The girl "Perpetua" died at Moradinha, on the 1st of June, and on the 13th of the same month the remaining patients were convalescent.(b) When these dates are compared, the actual interval between the disappearance and re-appearance of the fever will be found to shrink considerably within *months*. The interval, in short, instead of being *months*, as stated by Dr. King, was little more than *one month*, or about the same as that between the last cases at Joao Gallego (the end of April) and the outbreak at Moradinha (the 30th May of the same year). By Dr. King's own account, the rainy season of 1846 did not set in until about the middle of August.

The note adds:—"Dr. Almeida, of Boa Vista, considered the disease alluded to as an aggravated type of the bilious remittent, and in such belief he positively continued until after the arrival of *a communication* from the British superintendent of Quarantine." In a foot note, it is stated, on the authority of Dr. King, that "Dr. Almeida was a general merchant, who sold a few simple drugs, and gave his advice gratis. It might hence be inferred, that his opinions, even if they had been fixed, could have been of no great value."

Dr. King held no such despicable estimate of Dr. Almeida's opinion, when he brought it forward, rather triumphantly, and in contradistinction to the opinion of every one else on the island, in his "Report," p. 4, to the effect that the disease at Boa Vista was "an aggravated type of bilious remittent."

In my "Remarks," p. 14, I adduced Dr. Almeida's evidence, given eight months before Dr. King saw him, and a letter written by Dr. Almeida six months after Dr. King left Boa Vista, showing clearly, that Dr. King was entirely in error regarding Dr. Almeida's opinion as to the nature of the disease. After this, any disparagement of Dr. Almeida must come from Dr. King with a bad grace. It is too late to tell us, now, that Dr. Almeida's real opinions do not suit Dr. King's views,—that they are not to be relied upon.

I am also enabled to assert, that no communication was ever sent, either directly or indirectly, to Dr. Almeida by the British Superintendent of Quarantine, nor did Dr. Almeida know anything of the opinions of Sir William Pym regarding the fever up to the time I left Boa Vista.

But, as it appears that, notwithstanding the evidence and the letter to which I have just alluded, doubts seem to remain, in some quarters, regarding Dr. Almeida's views and the nature of the fever that devastated Boa Vista, I am compelled, although most reluctantly, to append the following extract of a letter from Dr. Almeida to myself on this subject:—

"From conversations that Dr. Leao and myself had with Dr. King, we discovered, that his object was to prove that the yellow fever was not imported into this island by the steamer Eclair. He always found us opposed to this; and we proved to him by positive facts, that he was in error. I told him, that during nearly forty years' residence in Boa Vista, I had never before seen a case of yellow fever, either here or in any of the other islands of the Cape de Verds Archipelago; but that I had occasionally seen intermittent fevers at Rabil when, in the rainy season, the waters remained stagnant for some time. Dr. King has, in his report, been pleased to pervert these conversations to suit his own erroneous views, not remembering, perhaps, that to foist them upon the public he has misused the name of one who, like himself, is in the Profession."

In the same spirit, and proceeding from the same source, an attempt is made in the "Report on Quarantine," p. 107, to deteriorate the value of the evidence obtained at Boa Vista, the witnesses being described as poor and ignorant, giving their "evidence in the loosest possible manner; their statements as to details and occurrences alleged to have happened several months before the inquiry took place were received implicitly, without examination into the correctness of their answers and the credibility of their testimony;—all the witnesses of this class appear to have spoken under the influence of the strongest feeling of self-interest, with a view to establish a claim to pecuniary compensation, should they make out a case against the Eclair."

As the chief of these allegations against the people originated with Dr. King, one is led to inquire how, from such sources, was it possible he could obtain his "indubitable facts"? As to the length of time intervening between the occurrences and the inquiries into them, if this be raised as an objection, it must apply with greater force to Dr. King's inquiries than to mine, because I preceded him on the island by eight or nine months. As regards our respective methods of conducting the inquiry, I might waive the discussion of this part of the subject, and leave it in the hands of others, observing, however, that high legal as well as medical authorities have considered the value of the evidence in the very opposite light to that which the "Report on Quarantine" might lead people to suppose.(a)

The assertion, that the statements of the witnesses were received, "without examination into the correctness of their answers," is at variance with fact. When so many persons were examined, and upwards of 1600 questions answered, it could hardly be expected that some discrepancies would not occur. I think, however, it will be generally allowed that,

(a) Dr. King, in his Report, does not allude to the negative evidence derived from these sources, or, indeed, from any source whatever. This may be explained upon the circumstance of his never having visited any one of these places of refuge.

(b) Vide Dr. M'William's "Report," etc., pp. 94, 95.

(a) For Dr. King's method of inquiry, see Dr. King's Report, p. 4. The mode I adopted is to be seen in my "Report," and in the "Remarks," p. 11.

in every essential point, the evidence of the people tallies with that of the higher orders at Boa Vista, and also with the information that has since come to light from Consul Rendall and others.

In a case of this kind judgment ought to proceed, not from a few casual discrepancies, such as occur in the evidence, and which are so eagerly caught up in the "Report on Quarantine," but from the general tendency of the evidence. The order of events may be noted without precision as to dates; but in the main points, as regards the first attacks at the Fort, at Porto Sal Rey, Cahecada, at Boaventura, Estacia Velha, Fundo das Figueiras, and Joao Gallego, the dates are given so as to be correct within one or two days. There is less certainty about the dates of the invasion of the other villages by fever; but the first attacks are in every case defined, and the radiations of the disease are followed out more or less extensively from each of these foci.

I consider that the following observations on the *Summary*, contained in pp. 114, 115, of the "Report," to be justifiable from the whole tenour of the evidence adduced in the case of the Eclair and Boa Vista:—

1. The fever which broke out in the Eclair, when on the west coast of Africa, was the common endemic, which became altered in character as the cases increased at Sierra Leone, between Sierra Leone and Boa Vista, and at Boa Vista, is proved—

By the great proportionate increase of mortality at those periods.

By the report of survey of the medical officers, held Sept. 13, by order of Capt. Buckle, senior officer at Boa Vista, in which it is stated, "*the extremely malignant character of the fever which has resisted the treatment usually found successful in the common endemic fever of the coast.*"—(Admiralty Correspondence, p. 18.)

By the opinion of Dr. Carter of the Growler, who, according to a letter from Capt. Buckle to me, considered "the disease among the Eclair's crew at Boa Vista to be contagious," and, "therefore, by his advice," adds Capt. Buckle, "I restricted the intercourse between the Growler and the Eclair as much as the pressing nature of the service would admit.

By the opinion of Sir W. Burnett and of Dr. Bryson, who, on the ground of the disease having become contagious at the fort, account for the attack of Dr. M'Clure.—(Admiralty Correspondence, p. 55.)—"Fevers of Sierra Leone," etc., by Dr. Bryson, p. 134.)

2. The petty officers and a few of the sailors did get leave after the arrival of the Eclair at Boa Vista; but there is no reason to suppose, that any of those who had this indulgence were at all sick. The officers who lodged in the house at Santa Barbara, on the beach at Boa Vista, were removed from it the moment they had even a premonitory symptom of disease; the house was exclusively occupied by them and their servants, and none of them when sick were nursed by the inhabitants.

3. The washerwomen who washed the linen of the officers (the crew of men-of-war do not send their linen to be washed on shore) were not infected by reason of the washing. But, up to this period, two officers only had been on the sick list from fever; one for a period of twelve days, and the other for eighteen days, both cases recovering. The clothes of one of these officers only were sent on shore. The bedding and clothes of deceased persons were carefully thrown overboard. Moreover, it has not been contended that the power of fomites to propagate infection, is at all equal to that of intercourse with the sick.(a)

4. The labourers were not infected, nor did they infect their families while the Eclair was at Boa Vista; which is not to be wondered at, seeing that they had not, until the last, direct intercourse with the sick, although they mixed on duty with the small portion of the crew that remained healthy.

5. The Cape de Verds are within the yellow fever zone, and they have experienced severe outbreaks of epidemic fever; but never within the memory of man, either before or after 1845-6, was yellow fever known at Boa Vista, or at any of the other islands of the groupe.(b)

7. The physical and social conditions of Boa Vista are those which might originate fevers; but the theory of "localising influences," as applied to the yellow fever epidemy, signally failed, more especially at the Ravine of Rabil; where the alleged localising influences were in greatest abundance, there was the smallest mortality. Moreover, fever broke out at Moradinha, in the Ravine, where there was nothing like any appreciable, local, physical condition to produce it. The failure of this theory to account for the outbreak in July, 1846, was, if possible, still more remarkable; inasmuch as the fever on this occasion first appeared in one of the best ventilated and cleanest houses of the town, and the person first attacked was well supplied with the necessaries of life, and such was the case with the great proportion of cases that took place at this time. The disease for some time was confined to the very best part of the town. No rain fell until a month after the disease had re-appeared, and several cases had died before any rain fell.

How is the occurrence of these cases to be explained on the ground of a "localising influence," such as is alluded to in the "Report on Quarantine"?

These cases took place, not only in the cleanest part of the town, but in the cleanest houses of the town; there was no crowding; indeed, in the first case, the fine, large, airy house was occupied by one person and two native servants. The weather was beautiful; there was no rain for nearly a month afterwards, nor was there anything upon which to build even the slightest supposition of the existence of any epidemical constitution of the atmosphere at this period.

To assume that these cases were merely sporadic cases,—mere messengers sent to announce the near advent of another epidemic, may be a very convenient formula for the Board of Health by which to account for cases they cannot otherwise dispose of; but such a mode of explanation will not, I imagine, carry much weight with the Profession.

8. It is entirely erroneous to state, that yellow fever was prevailing at Porto Praya when the Eclair arrived at Boa Vista. No such disease prevailed at Porto Praya at this period, nor are there any grounds for supposing that it existed there at any other period.

9. With regard to the outbreak of the epidemics, both as regards 1845 and 1846, most severe and fatal cases had occurred before any of the alleged atmospherical or other phenomena had appeared. It is also to be borne in mind, that *the so-called sporadic cases occurred only in persons who had been exposed to a source of contagion.*

10. The epizooty did not take place until the end of the dry season of 1846, when the fever had well nigh left the island. The epidemy on the island of Boa Vista commenced on the 12th October, in the person of Anna Gallinha. Anna Texeira, her son, Manoel Affonso, and others, living in the same neighbourhood, were attacked immediately afterwards.

At Rabil, the first case was Luis Pathi, about the 25th September, the disease attacking his family in the beginning of October. Manoel Fachina's wife, living next door, and visiting Pathi, was attacked at this time, and many others in the neighbourhood within a reasonable period from the arrival at Pathi. The exemption of the eastern villages, and of some of the other villages for some time, may be explained on the ground of their comparative little intercourse with Porto Sal Rey and Rabil, and partly also from the adoption of precautionary measures; but their exemption seems wholly inexplicable if the disease is to be attributed to a general atmospherical cause.

I think, then, that the whole of the "countervailing considerations" assumed in the *Summary*, at pp. 114-15, of the "Report on Quarantine," to be "admitted" facts, are, in every essential point, entirely destitute of foundation.

Such conclusions as those contained in this *Summary* could never, in my opinion, have been arrived at, had all the cir-

(a) Few, I imagine, will agree with Dr. King when he says, in his "Report," p. 7, "If the disease possesses the power of reproduction, its poison must have been as certainly communicated through the medium of fomites, as by direct contact with the sick on board, or at the fort."

(b) Some of the islands of the Cape de Verds have, within the last two years suffered from ague and remittent fever: but in no part of the documents in my possession regarding the disease, is there any sign of yellow fever mentioned. No case of black vomit occurred. In fact, the disease was perfectly amenable to common treatment. My friend, Mr. Thomas Miller, recommended by the Governor-General to the Portuguese Government for the decoration of the Order of the Tower and Sword, for his conduct during the sickness, took forty people from San Nicholao to St. Vinceut, during the height of the fever at the latter place. Nearly all were attacked; but one only, previously debilitated, died. The Consul, in his letter, states, "that no family nor person having the common necessaries of life, or the means of common treatment, died." Had the disorder been of the nature of yellow fever, those who had the means of treatment and the necessaries of life in greatest abundance, namely, the Europeans, as at Boa Vista in 1845-6, would have suffered most. But the very reverse of this was the case, for the blacks suffered most—nay, almost exclusively. The disease, in short, was maintained by exposure to vicissitudes of weather, and by starvation.

cumstances in the Eclair and at Boa Vista been fairly and impartially weighed. Nor do I believe, that they will be received by any one who will take into account the numerous mis-statements in the "Report on Quarantine," which I have pointed out and corrected, and the omission, in that document, of so many matters important to the elucidation of the truth, which I have taken leave to supply.

In my humble opinion, the history of the epidemy at Boa Vista comprehends every condition upon which the proofs of the infectionsness of a disease are supposed to rest, namely :—

The healthiness of the island before the arrival of the Eclair, with Yellow Fever on board.

The outbreak of the same disease among the inhabitants of the island within a reasonable period afterwards.

The immunity of distant villages for long periods until the arrival of infected persons, and the radiation of the disease in every district from infected foci.

The comparative immunity from the disease obtained by persons who adopted common but partial precautionary measures against infection.

The absolute immunity from the disease procured by persons who adopted strict measures of isolation and segregation.

Before closing this communication, I am desirous it should be distinctly understood, that none of the observations I have taken leave to make on the "Report on Quarantine" are intended to apply to either of the lay members of the General Board of Health whose names are attached to that document.

There is one passage, however, (that in which, at p. 101, the inhabitants of Boa Vista were charged with "giving their evidence under the strongest feeling of self-interest," to establish a claim for compensation," etc.,) to which I cannot help regretting that they should have given even an official concurrence.

The inhabitants of Boa Vista, consisting chiefly, in fact almost exclusively, of the negro and mixed races, badly educated, in a great measure destitute of the benign influence of religion, living on a wretchedly arid soil, with the curse of slavery as part of their social system, are, it is true, generally "poor and miserable;" but it does not follow, that, even under these adverse circumstances, all virtue in human nature should be supplanted by fraud and dissimulation. I was in every village, and I spent much time among the people; and I feel assured, they gave their evidence freely and candidly; and to charge them with exaggerating their statements from selfish motives, I feel to be as unjust as it is ungenerous.

It is to me a matter of deep regret, to find the honoured name of Lord Shaftesbury, connected as it ever has been with noble and philanthropic sentiments and feelings towards the lower classes, *whether black or white*, of all countries, giving even official sanction to so unworthy an insinuation.

As respects the medical member of the Board, he is no longer young; he is a respected member of a Profession honourably distinguished for its humane character and tendencies; and it is said that, at a former period of his life, he exercised a higher and even more sacred function. From such a quarter, one might have expected some degree of caution in giving countenance to an aspersion against a poor, but industrious and generous people, which, on further inquiry, he might have found to be wholly unmerited.

It is, however, consolatory to know, that the Government of this country were in no degree influenced by any such ungenerous views. A handsome sum of money was transmitted by the British Government to the distressed islanders, which, with the donations of provisions from Portugal, from the late Mr. Macaulay, from the English Consul, from the Messrs. Miller, of San Nicolas, and other benevolent sources, must have relieved much distress, and proved the saving of many lives.

Judging from what I saw in 1846, when distributing to famishing women and children the large amount of provisions brought me by Commodore Jones in H.M.S. Penelope, and the liberal supplies also sent from Sierra Leone and the Gambia, I feel satisfied, that the bounteous charity of the British Government was met by the blessings and the gratitude of the whole population of Boa Vista.(a)

Trinity-square, Tower-hill.

(a) Never was relief to a beleaguered and starving garrison more welcomely and thankfully received than were the provisions brought me by Commodore Jones, in H.M.S. Penelope. This bountiful and well-timed supply consisted of Rice, 210 large bags; Farinha de pao, 50 bags; Guinea corn, 50 bags; besides several boat loads of Yams.

I may, perhaps, be pardoned for yielding to the temptation to make the following extract from my private journal on the occasion of the first day's distribution of the provisions among the people:—

"With Dr. Almeida, the Mayor, Senhor Joao Baptista, and John Jamieson, employed the greater part of the day dealing out provisions to the people, who are in great want. It was a goodly sight to see their black, shining faces full of joy and thankfulness as they received their loads, varying in amount according to the number in the family. No Englishman could look upon this scene without being proud of his country. Thousands in this comparatively little known island are starving; no sooner is this known, than the gladdening hand of British generosity is at once extended to them. 1118 persons relieved this day. This is something to sleep upon."

ON THE MEANING OF THE TERM "ULCERATION,"

AS AT PRESENT APPLIED TO UTERINE DISEASES.

By T. SNOW BECK, M.D., F.R.S.,

Physician to the Farringdon General Dispensary and Lying-in Charity.

The conflicting opinions which have been expressed by practitioners as to the absence or presence of ulceration at the orifice of the uterus, appear only to be accounted for by referring to the different senses in which this word has been used. At first sight it appears strange, that two opinions should exist as to the meaning of a word the definition of which is so generally agreed upon; yet it is, nevertheless, certain, that in regard to the diseases of the uterus, it has been employed to denote morbid conditions which are very different from ulcerations, in the received acceptation of the term.

The definition given by all surgeons is essentially the same. Thus, for example, Boyer states: "an ulceration is a solution of continuity of the soft parts, more or less ancient, accompanied by a purulent secretion, and kept up by some local or internal cause;" and Samuel Cooper says: "Surgeons usually define an ulcer to be a solution of continuity in any of the soft parts of the body, attended with a secretion of pus, or some kind of discharge.(a) Authors on practical medicine and pathology likewise adopt a similar definition. Dr. Copland considers "ulceration is distinguished from suppuration chiefly by its being attended by a loss of substance, by a destruction of parts, and by a more or less abundant secretion of puriform, ichorous, fetid, sanious, or variously-coloured fluid."(b) Dr. Watson writes: "We may say, with Dr. Alison, that, whenever the absorption of the effused lymph, and of the surrounding textures, takes place in excess—in a greater degree, that is, and more irregularly than seems to be required for any useful purpose—the result is *ulceration*. The term is, however, commonly restricted to those cases in which the loss of substance occurs upon some *surface*, internal or external."(c) Dr. Williams defines an ulcer to be "a solution of continuity or excavation, the bottom and edges of which continue to discharge pus, or a serous fluid mixed with exudation corpuscles, and sometimes blood corpuscles."(d) Chomel states, that "ulcers are solutions of continuity maintained *(entre tenues)* by an internal or local disease.(e) Andral says, "The term ulcer is applied to that solution of continuity which is produced in a tissue by the absorption of its molecules.(f)

According to these definitions, to which many more might be added, the essential character of ulceration is a solution of continuity or excavation, or a loss of substance in a part; for it is evident, that the discharges which usually accompany this lesion are not characteristic of, nor essential to it, inasmuch as they are also products of simple inflammation of a mucous membrane. The accuracy of these definitions are confirmed by more recent observation of morbid phenomena by the aid of the microscope, which has shown, that, previous to ulceration taking place, the blood becomes stagnant, and adheres to the walls of the vessels, that the neighbouring tissues thus lose their vitality, by changes similar to what occur in mortification, and, being carried away by effused fluid, a solution of continuity, or loss of substance, is produced. To express this series of morbid changes in a short phrase, many pathologists define ulceration as "molecular death," or "molecular

gangrene." But this does not in any way alter the essential character of the previous definitions; for, when "molecular death or gangrene" occurs in any tissue, "a solution of continuity, or loss of substance" in that tissue is the inevitable result.

Admitting, then, that these definitions correctly express the essential character of ulceration, we may inquire, whether this term has been applied with propriety to many morbid states of the orifice of the uterus. At the late discussion at the Royal Medical and Chirurgical Society, Dr. Murphy is reported to have said: "A girl was admitted into the hospital (University College) dying from the effects of opium. At the autopsy, he had examined the uterus, and found an ulcer on both lips extending into the cavity. It was seen by the pupils, and was sent to the curator to be preserved, but the next day it had lost all its characters, and was thrown aside."(a) With all respect to Dr. Murphy's deservedly high standing in the Profession, and the personal esteem which must be felt by all who know him personally, I can only come to the conclusion, that some source of error must exist in this statement. A solution of continuity, or a loss of substance, on the lips of the uterus, would have been as readily recognised the day after the autopsy as on the day of the examination; and, if the supposed ulceration "had lost all its characters the next day," is it not certain that ulceration had not existed, and that some other morbid appearance had been mistaken for it? How could the loss of substance be repaired? And, if still present, it would have been recognised. I feel the greater confidence in speaking upon this subject, since I have carefully searched during some years for these reputed ulcerations in my own practice, and in the hospital practice of other physicians without being enabled to discover them. During this period, I have seen many cases of inflammation of the mucous membrane covering the lips of the uterus, and even extending into the cervical canal, which presented a red and granular appearance, and which had been designated ulceration, but wherein no loss of substance or solution of continuity existed. Sometimes the glands in the mucous membrane were chiefly implicated in the inflammation, and each being surrounded by a defined circle of redness, they presented, when grouped together, a circumscribed and defined granular patch, studded with minute pits or holes, which led to the orifices of the glands. In these cases, the pathological condition did not differ from that of chronic inflammation in other mucous membranes, as, for example, in the granular condition of the conjunctiva; in the state of the mucous membrane of the stomach, to which the name of mammillation has been applied, in the condition sometimes observed in the urethra of the male after gonorrhœa, etc. In these instances, there is no loss of substance in the membranes, nor has any one contended that ulceration was present; yet this name has been applied to the same morbid conditions when observed in the mucous membrane of the vagina, or in that covering the lips of the uterus. With this explanation, it can readily be understood, that an inflamed mucous membrane might lose its characteristic appearances the day after the autopsy, especially if it had been immersed in any fluid; but if a loss of substance or an ulcer had existed, that ulcer would have been as readily discovered the next day, as on the day on which the first examination was made.

At the same meeting of the Society, a letter was read from Mr. Holl, detailing the result of his *post-mortem* examinations, and bearing upon this subject. Dr. H. Bennet afterwards remarked: "That it appeared to him that Mr. Holl's guarantee for the correctness of his opinions was all that could be desired, as he was practically acquainted with the lesions to which that part is subject in the living state; that he had carefully examined the condition of the parts, and stated in his letter, —'The whole number of bodies in which the state of the uterus was examined was 44; of these, 34 either presented no disease of the cervix uteri, or only slight congestion, with the exception of 3, in whom the congestion was considerable. Of the remaining 10 cases, 9 of them presented more or less extensive abrasion of the epithelium from around the os uteri, but no ulceration. The pelvic veins were generally full of blood; the cervix uteri large, swollen, and puffy, with more or less venous congestion of the mucous and sub mucous tissues, but no induration or effusion of lymph into its texture. The glands of Naboth were enlarged, and the canal of the cervix blocked up with viscid mucus. The removal of the epithelium appeared to commence at the follicles which surrounded the cervix uteri.' Dr. Bennet, having read the letter, drew attention to the fact, that Mr. Holl, having a knowledge of these special lesions, and having specially investigated them in the autopsies, discovered 10 cases out of 44, or 37 per cent., in which there existed abrasion, or ulceration of the uterine mucous membrane.—conditions which he (Dr. Bennet) considered pathologically identical."(a) This, however, appears a perversion of Mr. Holl's words, who distinctly says, "there was abrasion of the epithelium, *but no ulceration.*" After lauding Mr. Holl's knowledge of these special lesions as offering a guarantee,—all that could be desired for the correctness of his opinions,—it appears a singular proceeding to ignore his knowledge, and contradict the opinion founded upon it. Would it not have been more consonant with the facts to have stated, Mr. Holl said he had found nine cases of abrasion of the epithelium, but no ulceration; yet this statement was erroneous, as, in reality, these were cases of ulceration? And that this conclusion was come to, in opposition to the former praise, because abrasion of the epithelium and ulceration were considered conditions pathologically identical. But is this the fact? Are these lesions pathologically identical?

The essential character of ulceration—that it is a solution of continuity or loss of substance in a tissue—has been sufficiently proved, and the pathological changes which occur have been also pointed out. In abrasion, or excoriation, the epithelial covering of the mucous membrane is removed, but the substance of the membrane itself remains uninjured. There is no solution of continuity, or excavation, or loss of substance in the part, and this constitutes the essential difference between the two lesions—abrasion, or excoriation, and ulceration. The pathological changes which occur are equally distinct. In ulceration, the blood becomes stagnant, adheres to the sides of the vessels, the vitality of the part is destroyed, molecular death or gangrene being induced. In excoriation, the blood flows on without interruption or stagnation; a portion of serum is effused beneath the unorganised epithelium, which, being detached, is subsequently removed. The changes which occur may be compared to the effect of an exceedingly minute and mild blister, active in its character, acute in its course; whilst ulceration is the consequence of minute mortification, usually slow in its action, chronic in its course. The difference between the two lesions, and the pathological changes which occasion them, thus appear to be well defined; but there is one point of view from which the two might be confounded. The first change occurring in a mucous membrane about to undergo minute gangrene is, in some cases, the effusion of bloody serum beneath the epithelium, and the subsequent desquamation of this part. And if we were to inquire no further into the changes going on, it might be concluded that, as there is desquamation of the epithelium in the beginning of the process of ulceration, and also in excoriation, that hence the two states are pathologically identical. But this would be a very superficial mode of considering the question. In the changes which produce ulceration, desquamation of the epithelium is not the only alteration which takes place in the membrane; for, after its removal, the surface appears livid and dark-coloured, the tissues having lost their vitality, and the vessels of the part being blocked up, as in mortification. But in excoriation, the separation of the epithelium is the first and only change which occurs in the tissues of the membrane, which, after its removal, appears red and florid, the vessels being pervious, and the blood circulating through them. Excoriations, then, are the consequence of inflammation of the mucous membrane, or, as some have expressed, of catarrhal inflammation, more or less acute; ulcerations are the results of molecular gangrene, or mortification, the sequence of disease extending into the deeper tissues of the organ. Thus, even from this point of view, it would be illogical and erroneous to consider these two morbid conditions as pathologically identical.

The importance of this subject is greatly increased when considered in relation to the treatment of the diseases of the uterus. From many communications I have received, I have no doubt that the idea of having so loathsome a disease as "ulceration" on the uterus, has induced many females to submit to the employment of the speculum, and escharotics; while the same term has been considered by practitioners as

(a) *Medical Times and Gazette*, Feb. 7, p. 144.

(a) *Medical Times and Gazette*, Feb. 7, 1852.

a justification for this mode of treatment. It is thus intimately connected with the proper or improper use of the speculum, in the treatment of uterine disease. Where ulceration really exists, which is very rare, unless it be specific ulceration, the local application of escharotics by the aid of the speculum, during the later stages of the disease, is, no doubt, an useful adjunct to the other means of cure; but when excoriation only is present, or a reddened and swollen state of the mucous membrane, conditions which accompany inflammation more or less acute, the employment of these therapeutical agents is not only improper, but frequently most injurious.

It appears to have been overlooked in the discussions on this subject, that neither excoriations nor ulcerations are, in themselves, the essential disease; but that they are merely symptoms or evidences of the existence of other diseases which have produced these morbid states. This is well shown in Mr. Holl's account of the morbid appearance, where "the pelvic veins were generally full of blood; the cervix uteri large, swollen, and puffy, with more or less venous congestion of the mucous and submucous tissues, but no induration or effusion of lymph into its texture. The glands of Naboth were enlarged, and the canal of the cervix blocked up with viscid mucous,"—distinct evidences of inflammation of the substance of the organ,—while "the removal of the epithelium, which appeared to commence at the follicles surrounding the cervix uteri," was but a sign of this inflammation affecting the glands imbedded in the tissues of the part. Viewed in this light, the application of escharotics to remove a symptom, whilst the disease producing it is unheeded, is undoubtedly not the correct course to pursue; nor can it be correct to endeavour to remove the symptom of acute inflammation of the mucous membrane—excoriation—by the application of substances which increase the inflammation already present. This mode of designating a reddened and swollen mucous membrane an ulceration, and including in one groupe diseases which are pathologically distinct, and which require opposite methods of treatment, has been productive of a serious amount of mischief in the treatment of uterine affections. Thus, in subacute inflammation of the mucous membrane of the vagina, where the membrane is red and swollen, and where the symptoms were, pain deep in the hypogastrium, pain on passing the fæces or urine, a mucous or purulent vaginal discharge, with pain across the forehead, and other constitutional symptoms, I have known the speculum employed, and the nitrate of silver applied, in consequence of the practitioner being misled by the idea that extensive ulceration existed. As might be supposed, this treatment was followed by great increase in the symptoms for several subsequent days, without any permanent advantage. On the other hand, in some exceptional cases of chronic vaginitis, which chiefly involves the upper part of the vagina, and where lotions have been inefficiently employed, either from inattention or want of management on the part of the female, the local application of strong stimulants has altered the morbid action, removed the thickened or mammillated condition of the membrane, subdued the vaginal discharges, and other symptoms. But these are only exceptional cases, and, by no means, form the general rule. Similar errors have been committed in respect to the diseases of the uterus itself. In cases of inflammation of the organ, the redness of one of the lips, or the red appearance of the lining mucous membrane, have been treated by the application of escharotics, and followed by much augmentation of the inflammatory action in the deeper tissues. Even in those cases where ulceration, or a loss of substance, has really existed, much injury results from concentrating the attention too much upon this lesion, and neglecting the diseases or morbid states to which it owes its origin. What surgeon would think of applying powerful local applications to an ulcer on the leg, in the expectation of curing it, until he had first removed the state of the venous circulation upon which the continuance of the ulcer depends? Yet this is exactly what has been continually done in the treatment of the diseases of the uterus.

These principles were well expressed by Professor Dubois, during the discussion before the Academy of Medicine at Paris, in 1850:—"The value which has been given by one of our colleagues to ulcerations, if this were real, leads to consider them as one of the local conditions the most worthy of attention in practice. I cannot, for my part, adopt this manner of view; according to my appreciation, these lesions, as well as 'engorgements,' are only consequetive phenomena of another alteration (inflammation) which has preceded them, and have in general, in regard to the symptoms and treatment, but a secondary importance," *Bulletin*, p. 225.

9 A, Langham-place.

THE LONDON PRACTICE OF MEDICINE AND SURGERY.

LONDON HOSPITAL.

By NATHANIEL WARD, Esq., F.R.C.S.

EXTENSIVE NECROSIS OF THE RIGHT FEMUR—EXCISION OF PART OF THE SUBSTITUTE BONE—REMOVAL OF A LARGE SEQUESTRUM—RECOVERY.

A lad, aged 16, came under the care of Mr. Luke, with extensive disease of the right femur. The entire shaft was much enlarged, and the soft parts immediately surrounding it felt dense, and yielded but little on pressure. There existed three sinuses leading down to the bone: one at the upper third of the front of the thigh; another at the outer side, a little above the middle; and the third two inches above the knee-joint. All of them gave free exit to thick pus, which came away, however, more freely from the lowermost. A probe introduced through the lowermost opening led down to dead bone, which seemed to yield somewhat, on pressure being made by the instrument, which could be passed somewhat in front and somewhat behind the bone. There were cicatrices of several other abscesses that had formed at different periods, on the front of the thigh, and in the popliteal region. The patient stated, that five years ago he had, while bird-nesting, fallen from a tree, and shortly afterwards a boy gave him a kick in the right ham. An abscess formed gradually and broke. It healed in about seven or eight months. Four months after this another formed at the lower and outer part of the thigh, which has never healed. The formation of the latter was soon followed by others in different parts of the limb, the greater part of which, however, soon cicatrised.

The patient having been kept quiet in bed, with the limb somewhat elevated, and having been placed on a generous diet for the space of three weeks, was brought into the operating theatre, and placed under the influence of chloroform. A director was introduced through the sinus, at the lower and outer part of the thigh, down to the bone; a long, narrow, and strong scalpel was passed into the groove, and an incision three inches in length, almost vertical in direction, was carried upwards; the director was then removed, and the incision prolonged downwards to the extent of an inch through the lower part of the sinus. The soft parts were now held back by two bent spatulæ, and when the smart hæmorrhage that came on after the incision of the soft parts had so far subsided as to admit of the substitute bone being exposed to view, Hey's saw was applied to it to the extent of about two inches. The new bone having been divided longitudinally to this extent, a lever was inserted, and, by several applications of it, enough of the new bone was removed to expose the necrosed portion. Its lowermost extremity was impacted in the cancellated structure below the level of the incision made by Hey's saw. The sequestrum was therefore cut in two portions by a pair of Liston's forceps; the upper portion was seized, and, by powerfully drawing it downwards and rotating it somewhat at the same time, was removed from the interior. The lower fragment was next removed by pulling it upwards and rotating it at the same time. The sequestrum altogether measured about six inches in length, was about half an inch in diameter, and had the ordinary worm-eaten appearance of similarly situated necrosed bone. The wound in the thigh was lightly dressed with wet lint, and the limb placed on an inclined plane. Considerable constitutional disturbance came on after the operation, and lasted for about four or five days. On its subsidence, the generous diet which the boy had had on his admission was resumed, the wound took on a healthy healing process, and he left the hospital on the seventy-ninth day after the operation, the wound having all but healed.

NECROSIS OF THE RIGHT FEMUR—EXCISION OF PART OF THE SUBSTITUTE BONE—REMOVAL OF SEQUESTRUM—RECOVERY.

Case 2.—A fisherman's son, a pale, weakly-looking lad, aged 14, came under the care of Mr. Luke. There existed at the inner and fore part of the lower third of the right thigh a sinus leading down to dead bone. The shaft of the bone was much thickened at the middle and below it. The boy stated that he was quite well fifteen months ago, when a boy gave him a kick. No pain followed the

injury except immediately after its infliction; but two or three months afterwards a large abscess formed at the lower and inner part of the thigh, when he was on shipboard in Holland. He came home, and went to the Dreadnought Hospital, where the abscess was opened. He remained in that hospital nineteen weeks, and came shortly afterwards to the London Hospital, under the care of Mr. Luke, under whose treatment he remained for five weeks; he was then discharged for a short time, as it was thought that the sequestrum was not at that time sufficiently advanced to admit of any operation for its removal being attended with success. He was re-admitted in between five and six months' time again, under the care of Mr. Luke, who handed the case over to Mr. Critchett. Having remained quiet in the hospital for about three weeks, the patient was placed under the influence of chloroform, and Mr. Critchett proceeded to the removal of the sequestrum. An incision two inches and a half long was made down to the bone, commencing from the sinus which led to it, and continuing upwards and outwards, so as to get away as much as convenient from the vicinity of the femoral vessels. Another incision, an inch long, and transverse in direction, beginning from the commencement of the first, was carried through the soft parts outwards. The triangular flap thus circumscribed was reflected, and the shaft of the bone exposed. A piece of necrosed bone, equal in size to a sixpence, irregular and jagged in outline, was removed from the surface of the shaft, the substitute bone being here deficient. The chisel and mallet were applied to the substitute bone, external to this necrosed portion. A piece of the former was removed, and the sequestrum brought to view. This was extracted, after it had been cut into two pieces by the bone-forceps; but, being more friable than the sequestrum in the preceding case, the two fragments broke in extraction, and several applications of the forceps were required for the complete removal of the dead portions. After the sequestrum had been taken away, a cavity existed in the centre of the shaft, extending two inches upwards, and into which the lower two-thirds of the index-finger could be inserted. The cavity extended downwards about an inch. The hæmorrhage which, during the steps of the operation had been considerable, subsided shortly after the removal of the sequestrum, and the wound was lightly dressed with lint soaked in warm water, and oiled silk. Secondary hæmorrhage, to a slight amount, occurred after the removal of the patient to bed. The wound was lightly poulticed for several weeks, the granulation process quickly took place, and in two months the wound had cicatrized, having latterly been dressed with a weak iodine lotion.

NECROSIS OF THE TIBIA AFTER FEVER—EXCISION OF SUBSTITUTE BONE—REMOVAL OF THE SEQUESTRUM AT THREE DIFFERENT PERIODS—RECOVERY.

Case 3.—A lad, aged 16, came under the care of Mr. Curling, having, a month prior to his admission into the hospital, been attacked with fever. During his progress to recovery from it, a large abscess formed in the right leg, in consequence of inflammation. He was then under the care of Mr. Wordsworth, who opened the abscess, and recommended the patient's removal to the hospital. On his admission, he was pale, feeble, and emaciated. The right leg presented several sinuses, freely discharging pus, along the course of the tibia. These sinuses led down to dead bone, which, however, gave no evidence of being loose. A barely appreciable enlargement of the limb existed. Under treatment, the patient's health gradually improved, and, with this improvement, the discharge from the sinuses lessened.

In about six weeks from his admission, the tibia was observed to be gradually enlarging, and at the end of the third month had attained a great size, accompanied with pain in the limb, increased on pressure, and a dark red appearance of the skin of the lower half of the leg, and a diminution of constitutional power. About a fortnight after this, one of the fistulæ at the middle of the leg took on the character of a sloughing sore, and was treated by the free application of nitric acid and subsequent poulticing. Morphia at night time, sarsaparilla with dilute nitric acid, and wine, during the day, were given internally. In about ten days, the wound had assumed a healthy granulating surface, a thin scale of bone having previously separated. Shortly after this, a similar process supervened in one of the upper fistulæ, and the patient's health sensibly gave way. At the end of the sixth month from the commencement of the disease in the tibia, Mr. Curling removed part of the sequestrum. The boy having been placed under the influence of chloroform, and the anæsthetic effect having been kept up by ether, a flap of the skin, including the granulating sore in the middle of the leg, was reflected. A large triangular piece of the substitute bone was removed by Hey's saw, and the necrosed bone exposed. It was divided by the forceps, and portions of it were separately removed by the elevator and forceps. The greater part of the sequestrum, however, was so firmly imbedded, that it was deemed advisable to postpone its entire removal. The wound was dressed with lint and warm water. In the course of three months the large wound in the leg had healed.

About five months after the first operation, a second was had recourse to. The boy was again placed under the influence of chloroform and ether, and a free crucial incision was made over the upper part of the tibia, and with Hey's saw some thick pieces of substitute bone were removed. A large sequestrum was extracted, forming at one part the whole calibre of the tibia. The second operation was more severe than the first, and from it the boy's constitution apparently suffered a good deal. Three months after it, the wound had all but healed, and the patient had become quite robust and healthy in appearance, having been sent to the sea-side for eight weeks. A week after his return, a third operation was had recourse to, and a necrosed portion of bone extracted, three inches in length, in two fragments, an oblong piece of the substitute bone, two inches and a quarter long and half an inch in thickness, having previously been taken away by Hey's saw. The wound soon took on a healthy character, and had quite healed in three months. The patient left the hospital cured, in the sixteenth month after his first admission, and he has at the present time a very useful leg, which has become reduced to the same size as the unaffected one.

Remarks.—The above cases belong to a class particularly interesting to the surgeon, inasmuch as by a timely and skilful operation, a limb, which had possibly been useless for years, is soon restored to its original functions, and the patient withdrawn from a danger which threatened sooner or later to produce a serious effect on his constitutional powers.

The period at which an operation should be undertaken for the removal of a dead portion of bone, when enclosed in a canal of substitute osseous deposit, is clearly more difficult to determine than when necrosis has taken place without such new deposit existing. In the latter instance, the looseness of the dead portion can easily be detected, and by the aid of the forceps and a division of the soft parts and sinus leading down to the dead bone, can be as readily removed, being usually small in extent and superficial in position. In the former instance, the necrosed portion becomes so intimately impacted in the deposit of new bone, that it is very difficult, if not at times impossible to detect that the dead portion is loose by a probe, steel director, or other instrument passed down through one or more cloacæ that communicate with it. Generally, however, when the process of necrosis is quite complete, the fibrinous deposit, which intervenes between the dead and living portions, and which admits of yielding somewhat on pressure being made on it through the medium of the sequestrum, comes in aid of the diagnosis. An experienced and educated hand will not unfrequently be able to detect this yielding, which might not be made out by one less expert. It constitutes a valuable symptom, and, when taken in conjunction with copious discharge and considerable development of the substitute shaft, sanctions at once the propriety of an operation.

The third case presents many points worthy of attention. The patient had originally been healthy; the disease came on in the tibia after an attack of fever, and was very acute and rapid in its course. The formation of the substitute bone took place with almost equal rapidity, and, at the third operation, was half an inch in thickness. The effect of this rapid development of new bone was very remarkable; for, at the commencement of the increase in the volume of the limb, a state of active inflammation supervened in the superficial parts, leading to the formation of several sloughing ulcers; this condition appearing to depend on a great degree of tension, brought about by the infiltration of the soft parts between the integument and the bone. To relieve this condition, it became necessary to deviate from general principles, and to perform the operation for the removal of the dead bone before the process of separation from the living was complete; and by three distinct operations, judiciously had recourse to at most favourable periods, nearly the entire original shaft of the tibia was removed, and the patient made a quick recovery, with a useful limb.

PUBLIC DISPENSARY, CAREY-STREET.—At the anniversary dinner of the Governors of this Institution, held lately, His Royal Highness the Duke of Cambridge in the chair, the report stated, that since its establishment in 1782, the total number of patients admitted was 225,688, of which upwards of 45,000 had been visited at their own homes. The average yearly number was 6,000, 1-6th being attended at home. The removal of the Dispensary from Bishop's-court had caused an expense of 360*l.*, and a debt of 700*l.* has been incurred. A subscription on behalf of the Charity was entered into in the room.

LIST OF SCIENTIFIC MEETINGS FOR THE WEEK.

This Evening,	May	29.—Royal Institution. *Subject:*—Prof. Faraday, "On Points Connected with the Non-Metallic Elements." Three o'Clock.
——	——	Medical Society of London. *Subject*:—Dr. Merriman, "On Artificial Dilatation of the Os Uteri. Eight o'Clock.
Monday,	May	31.—Royal Institution. *Subject:*—J. Conolly, M.D., "On Insanity." Four o'Clock.
Tuesday,	June	1.—Royal Institution. *Subject:* — E. Lankester, M.D., "On the Physiology of Plants." Three o'Clock.

SATURDAY, MAY 29.

BETHLEM HOSPITAL.

The more we hear of the contemplated changes in the *ménage* of this Institution, the more confidently are we confirmed in our opinion. The correspondence of the Physicians shows that, notwithstanding the quibbling, and air of mystery with which the Governors surround the matter, the Sub-Committee, and their primitive system of management, are the real objects of the Commissioners' censure.

The restriction placed by the Secretary of State as to the circulation of the evidence taken before the Commissioners appears at first sight to be a matter of hardship to the Physicians; for their retirement subsequent to the inquiry is almost compelled, although, the Governors say, not in consequence of it. On the other hand, it may be said, and not without justice, that the evidence containing nothing to inculpate them, its limited circulation among the Governors and their Sub-Committee must not be deemed so unfair as it would seem. We hope, however, that it will yet be obtained from the authorities, and made public.

We have heard, that the Commissioners' remonstrance to the Governors has shaken in their seats some prominent officials. During the inquiry, rumour was rife, that the worthy Treasurer anticipated the necessity of seeking once more the peace and calm of country life; but reminiscences of his comfortable official dwelling, and its sweet contingencies, gave him fresh courage; and, with his companions of the Sub-Committee, he determined to avoid dismissal by submitting to the Commissioners, confessing long abuses of privilege, and promising future amendment.

We are not altogether uninformed; and we know that the chief point upon which the Commissioners insisted was the insufficiency of the present management to obtain for the Institution its legitimate objects. The system of Visiting Physicians was condemned, but not the Physicians; the accumulated duties of the resident officer, rendering useless all his efforts fully to perform them, did not escape without reproof; and the paltry and niggard parsimony of the Sub-Committee, in not allowing a proper number of efficient attendants to watch over the wants and necessities of the unfortunate patients, was a special object of inquiry.

To this latter cause are to be attributed the many accidents which have occurred in this establishment,—the escapes, and several suicides; and to this, also, are to be ascribed the many complaints of harshness and ill-treatment which have called for the Commissioners' interference.

Whoever is conversant with modern establishments for the insane, will be surprised that Bethlem is only old Bethlem improved, and not what Bethlem ought to be in 1852. Who could walk along its galleries, and not be struck with its gloom and chilling dulness? Who has visited its dark and prison-like, its ill-warmed and whitened cells, and not felt that improvement was necessary? What rays of sunshine gladden and cheer its desponding and unhappy inmates? All this was not unheeded; and, if report be true, the old wooden, rough bedsteads, with their canvass bags of straw, coeval with Moorfields, were not unnoticed by the Commissioners. The old prison window, the absence of proper airing courts, and the judicious division and separation of patients, the ill-divided jurisdiction and authority of the physician, the steward, and the matron, were alike subjects of animadversion, and, we hesitate not to say, just yet gentle reproach.

We feel fully convinced, that it is for the proper digestion and consideration of these vices and evils, and the miseries which must have resulted from them, that the Secretary of State has chosen to limit the circulation of the report. May its private examination produce a good effect! May the Sub-Committee listen to, and practise, the various wise suggestions which the new superintendent will doubtless offer; but which, coming from their Physicians, were unheeded! May they be taught to know that words of wise counsel and cheering comfort, poured by a judicious attendant into the ear of the miserable maniac, may dispel his delusion, and restore distracted reason to her once calm throne!

No men of mark, however, have as yet *publicly offered* themselves for the new appointment at Bethlem. We observe, by the Daily Press, that Dr. Wood, *now* resident there, is a candidate; also Dr. Hood, of Colney Hatch, who advertises himself as "a married man, with four children." As a relative of some city officer, he is spoken of as likely to be appointed,—spoken of, we say, for the day has gone by when nepotism, even with a wife and four small children, can command sweet voices and support.

But, to do justice to the Governors, and to their avowed intention of choosing the best man they can get, we are glad to understand that the appointment has been suggested to Dr. Browne, of Dumfries—the Conolly of Scotland, as the institution over which he has long so ably presided is the Hanwell of the Sister Kingdom. Dr. Browne's "reports" have always struck us as being of the highest order; he has done much towards arriving at a sound knowledge of insanity and the rational treatment of the insane; his asylum —the Royal Crichton Institution—is the admiration of all who visit it, and the model upon which all similar establishments should be conducted. As a lecturer and teacher, Dr. Browne is only second to, if he does not equal, Dr. Conolly himself; he has proved himself fully adequate to the duties of the new appointment; and if Ambition, that rabid mother of many woes, will bring him to London —for that which he now holds is pecuniarily equal to that which is offered—we know no one worthier than he to rule at Bethlem. Dr. Browne is one of those whose antecedents in lunacy entitle him to claim the highest rewards that department of the Profession has to bestow.

Mr. Hill, the excellent originator of the non-restraint

system, has also worthily been pointed out for the post. To him the cause of humanity owes many debts; but, to whomsoever the appointment may be given, we envy him not, if all that is said be true of the duties he will have to encounter. His will be no easy place; from the chapel to the kitchens and the laundry, all is to be supervised by him; the duties of the matron, too, are to fall to his lot, for, in the midst of the turmoil, she, too, has resigned.

But, even with the best man that can be induced to accept the new appointment, the staff will still be wholly insufficient for its purposes, and the coming change will leave matters much as they have hitherto been. Out of the extraordinary tables which grace the "General Report,"—some amusing, some ludicrous, and a few of an instructive character,—we find one stating the daily average number of patients contained in the Hospital—curables, incurables, and criminals—amounts to 359. The future Medical Superintendent will have to inspect each of these patients *daily*, and at night to make surreptitious visits. He has, moreover, to keep the books, record the cases, and manage the servants. The 24 hours consist of 1440 minutes; now, giving two minutes to each patient, no very long time, we leave the unhappy superintendent a surplus of 722 minutes; of which, at least 359 will be occupied in traversing long galleries,—Dr. Hood, in this way, is said to walk at Colney Hatch nearly twenty miles a-day;—he must have two hours in the twenty-four for meals and rest, leaving a residue of 243 minutes, or four hours three minutes, for sleep, case-taking, book-keeping, the aforesaid nocturnal visits, and attendance upon the families of the officers attached both to Bethlem and the house of occupation. He must also be present at *post-mortem* examinations; and, as this is often a lengthy affair, the performance of his duties will become utterly impracticable.

We presume, the apothecary will enjoy a light and genteel business in preparing, dispensing, and administering medicines. The extraction of teeth, the administration of enemata, passing catheters, and keeping accounts, will, we presume, sufficiently occupy his leisure moments.

The establishment of a school for the study of diseases of the brain, and of the different forms of insanity, will, after a time, rectify many of these evils; inasmuch, as from the more proficient students, clerks or assistants may be selected, who will materially lighten the labours of the superintendent. It is worthy of remark, that the authorities of Bethlem have for many years set the example, now followed by most other public hospitals, of having the *post-mortem* examinations of the patients who die in the hospital conducted by one special officer, namely, the present distinguished surgeon. There is, consequently, a valuable record of autopsies, which have formed the basis of Dr. Webster's Report, printed in the "Transactions of the Royal Medical and Chirurgical Society."

We trust that, in the selection of the Superintendent, the Governors will not think it necessary to require either an *old* man, or one whose sphere of observation has been long limited by the dull brick walls of an asylum. If old, he is physically unfit for his work. If simply a keeper of a madhouse, he has, in all probability, been in a great measure severed from his Profession, and is deficient in that scientific and extended view of mental diseases necessary for their proper interpretation and treatment.

We cannot, upon the whole, help thinking, that it will be a wiser plan to select some man, about 30, who has distinguished himself in the London schools—we could name half-a-dozen such—and place him in Bethlem, rather than one old in insanity, and bigoted, probably, to his own opinions. Never mind his want of experience,—to what does the experience of the man who has lived long years in an asylum amount? Himself a learner, he will be better able to teach; and, coming without prejudice and preconceived notions, he is the more likely to render Bethlem all it ought to be.

There are many interested in the results of these proceedings. The East India Company has required that their Medical Officers shall study insanity before entering the service. The same regulation must soon be followed in the Queen's service; consequently we expect, ere long, that there will be a no inconsiderable class of students ready to avail themselves of the very large field of observation which Bethlem Hospital, with its curables, incurables, and criminal lunatics, is especially calculated to afford.

However, we have great confidence in Sir Peter Laurie, Mr. Northall Laurie, and Dr. Webster; and we are inclined to anticipate that the appointment, when made, will call for the unanimous approbation of the Profession.

PROVINCIAL CORRESPONDENCE.

IRELAND.

PATHOLOGICAL SOCIETY OF DUBLIN.

The last meeting of the Society for the session 1851-52 was held in the anatomical theatre of Trinity College, Dublin, on the 24th ult.; Sir Philip Crampton, Bart., Senior Vice-President, in the chair. The labours of the Society were brought to a close with the delivery of an address by the Chairman, on the occasion of presenting the Society's gold medal, for the first time, to the author of the best essay on a subject selected by the Council. In a former Number we announced, that the subject chosen for this year's competition was, "The Pathology of the Venous System;" and we have now the pleasure to state, that the medal has been awarded to Mr. John Barton, whose paper, under the fictitious signature of "Tandem," was, after a rigorous scrutiny, ascertained to be the most meritorious; it contained, not only a *résumé* of the opinions of the classic authorities on this difficult subject, but gave abundant evidence of the zeal and industry of the writer in the many valuable cases occurring during his hospital practice, which were given with much lucidity of arrangement and accuracy.

Sir Philip Crampton said, that it gave him very great satisfaction indeed to be made the organ of the Society on such an interesting and important occasion; and, though the Society since its projection and establishment by Drs. Stokes and Smith in the year 1838 had done much, not only to raise the character of the Dublin School, but also to promote the study of pathology in other cities, by the example of its successful working, he considered, that not among the least of its claims must be reckoned the great advantages which it afforded to the student of witnessing the results of disease on such a large scale. He would also call attention to the facilities which the recent arrangements of the Council had afforded to pupils, all the Society's meetings being freely open, and an honorary testimonial being granted to all students for regular attendance. He trusted that the honour which had been that day conferred on Mr. Barton, was but a presage of more important distinctions still in store for him; and in decorating him with the first gold medal of the Dublin Pathological Society, he felt assured he did not go too far in saying, that the possession of such a prize would insure him higher success in his professional career than the largest patronage or private influence.

QUEEN'S UNIVERSITY IN IRELAND.—IMPORTANT DECISION IN REFERENCE TO THE DEPARTMENT OF ANATOMY, DURING THE VISITATION OF THE QUEEN'S COLLEGE, CORK.

The first visitation of this College was held on Tuesday, the 11th of May, at the hour of one o'clock. The visiters present were, His Grace the Lord Archbishop of Dublin, the Right Honourable Baron Greene, the Lord Bishop of Cork, Cloyne, and Ross, the President of the King and Queen's College of Physicians in Ireland, (Dr. Wm. F. Montgomery,) the President of the Royal College of Surgeons, (Mr. Trant,) the Right Honourable Maziera Brady, Ex-Lord Chancellor of Ireland.

The President of the Queen's College, Cork, Sir Robert Kane, M.D., reported, for the information of the visiters, that in general the progress of the College had been exceedingly satisfactory; he

had had but little reason to complain of the conduct of the students; the infractions of discipline which had occurred having been of a trivial character; and in the professional circle harmony had existed, with the exception of certain instances on which he would not immediately dilate, as they would be brought before the Board of Visiters in due form. In reply to a question from His Grace the Archbishop, Mr. Albani, the registrar of the College, stated, that the number of students on the College books amounted to 147.

A memorial was read from Professor Benjamin Alcock, complaining of certain acts of the President and Council which had reference to the anatomical department under his charge, and which he conceived militated strongly against his interests and privileges, as in his opinion defined by statutory provisions.

Mr. J. D. Fitzgeral, Q.C., appeared for Professor Alcock, and begged to premise to the Court, that the question about to be submitted to them was entirely one of law. It appeared, that Dr. Alcock had been appointed Professor of Anatomy and Physiology by the Crown, in whom alone is vested the right to appoint a Professor. He believed that it would not be denied, that Dr. Alcock had been statutably appointed Professor of Anatomy and Physiolgoy; but the question for the Court to decide was, whether, as Professor of Anatomy and Physiology, he was not entitled to teach the course of Practical Anatomy also. From the opening of the College, in 1849, up to the prerent time, Dr. Alcock's memorial stated, that no Professor had been appointed to teach Practical Anatomy, and that being the case, and he being the statutably appointed Professor of Anatomy and Physiology, Counsel contended, that Dr. Alcock was entitled to teach the course of Practical Anatomy, and that the Council of the College had no right or jurisdiction to appoint any Professor in that department. Dr. Alcock further stated in his memorial, that certain professorial fees were, in accordance with the statutes of the College, paid by the students; and he further stated, that he had received fees from the students for the course of Anatomy and Physiology, and the course of Practical Anatomy, until the month of Dec, 1851, when certain resolutions were passed by the Council, under the advice and sanction of the President. The first resolution declared, that the department of Practical Anatomy should be conducted by a Professor of Anatomy and a Demonstrator appointed by the Council, and who should be under the control and supervision of the Professor. Here the Court would see, that Practical Anatomy was treated as a separate and distinct department, which was not to be under the control of the Professor of Anatomy and Physiology, but was to be conducted by a Demonstrator appointed by the Council. This Dr. Alcock, although most willing to appoint a Demonstrator of Practical Anatomy, (which he had already actually done,) objected to, as he denied the right of the Council to appoint any Professor, or to impose upon or relieve any Professor from the duties delegated to him by virtue of his appointment. The second resolution, in fact, vested in the Council the right, if it so chose, to appoint a Demonstrator; and the third was to the effect, that such Demonstrator should be paid out of the fees from the students of Practical Anatomy. Now, the memorialist contended, that no Professor or Demonstrator has a right to be paid out of the fees which the statutes give to him, and to him alone. Counsel dwelt at length on the various points of the case, and the bearings of the statutory provisions thereon, and cited the wording of the Charter in evidence of the justness of memorialist's claim; the practice of other institutions was also adduced, and more especially the usages of the anatomical department of the Dublin University.

The President urged, in reply, that, as it had been admitted by Counsel, that Her Majesty's Government had a perfect right to appoint a Professor of Practical Anatomy at any moment they deemed fit, the question was much simplified. It was in consideration, that no statutory provision existed whereby Dr. Alcock could fill the Chair of Practical Anatomy; that the College authorities had felt justified in taking the steps they did; and, for the better and more efficient management of the College, as well as for the benefit of the medical students, they appointed one who, though not statutably recognised as Professor, not having received his appointment from the Crown, was yet fully competent to undertake the duties which devolved on him. It was true, that, in the several documents adduced in evidence, Dr. Alcock had been styled Professor of Practical Anatomy, which, however, arose from a wish to put Dr. Alcock in a leading and prominent position, and from feelings of courtesy and kindness towards him.

The President adduced many further arguments, and explained how, likewise, difficulties would arise with regard to the recognition of the College certificates by the various licensing bodies, whose Boards refused to receive testimonials on more than one subject from the same Professor.

The visiters retired for half an hour, and, after consulting together, the Right Hon. M. Brady proceeded to deliver the judgment of the Court. The visiters admitted that a difficulty did exist with regard to the performance of the duties of the anatomical departments. But it would certainly appear, though not precisely so stated in the statutes, that the Professor of Anatomy and Physiology was the most proper person to have charge of the practical anatomy department, as the Professor of Chemistry would be the appropriate person to have charge of the department of practical chemistry. The course of proceeding in the University of Dublin likewise very much fortified such a view of the matter. Seeing that the Charter contained the names of subjects exceeding the number of the professors, and that it contemplated the delivery of a course of lectures upon those subjects by the professors only, it would appear that the Charter contemplated that some one or other of the professors should be the person to undertake these duties; it was, therefore, to be understood, that the delivery of the course of lectures upon practical anatomy would fall upon the Professor of Anatomy. The Charter assumed, that more than one course of lectures might be delivered by some of the professors; and if that were the case, and that, by reason of any allocation of a certain course not specially appointed to any Professor, the duty fell upon the person in the same range of study, he would be the person, *primâ facie*, entitled to receive the fees for such course of lectures. It would appear, therefore, that whatever assistance Dr. Alcock might require should be a matter for his own arrangement and for his own profit. There was no power in the College to appropriate the fees in any other way, for, if they received them, they had only one duty to perform, namely, to hand them over to the Professor who performed the duties of the department. It was another question, as to whether such an arrangement would be for the benefit of the College; but they (the visiters) were bound by the statutes, and, according to them, they should decide in favour of Dr. Alcock; and, as to the difficulty of this arrangement clashing with the arrangement of other institutions, it could be easily met by applying to the Crown to appoint a separate Professor of Practical Anatomy.

On the day following, some subjects connected with the arrangements of the Faculty of Sciences were brought before the Visiters; after which they inspected the museums, library, etc., and expressed themselves much pleased with all that related to the internal economy of the College. The Visitation then concluded.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

J. Hodgson, Esq., F.R.S., President, in the Chair.

A CASE OF HÆMORRHAGE FROM INVERSION OF THE UTERUS,

IN WHICH THE OPERATION OF TRANSFUSION WAS SUCCESSFULLY PERFORMED: WITH REMARKS ON THE EMPLOYMENT OF TRANSFUSION GENERALLY.

By JOHN SODEN, Esq., Surgeon to the Bath General Hospital.

The author begins by expressing his belief, that the evidence in favour of transfusion is not generally known, and that false notions prevail with respect to its dangerous character. Having had an opportunity three years ago of proving its power, he was induced to examine into the results of all the recorded cases, and has presented a table of thirty-six in which the operation was performed in connexion with the puerperal state. The thirty-sixth case was that in which transfusion was performed by himself. A lady was delivered of her third child rapidly, and the latter pains were so severe that the uterus was violently emptied of its contents, and became inverted; a gush of blood ensued, and the patient fainted. The placenta was detached, and the uterus returned; no further hæmorrhage took place. In half an hour the patient had not rallied, and was insensible, cold, pulseless, and exsanguine in appearance; the breathing was at long intervals, stertorous, and jerking. She could just swallow stimulants by teaspoonsful at a time, and every other means were used to restore her. After about an hour she became, however, worse; was no longer able to swallow, and the respirations became more rare and stertorous. Transfusion was then had recourse to. The opening was made in the external cephalic vein, and blood drawn from the husband was injected by means of an ordinary syringe of German silver, with a detached stop-cock, previously well warmed. At first the blood would not pass, but returned through the opening in the vein; presently the opposition, from the contact of the coats of the vein, seemed to give way, and the blood, though impelled by a steady and moderate

pressure, rushed rapidly up the vein. The effect was instantaneous; a convulsion seized the whole frame, and the muscles of the face were frightfully distorted: not more than an ounce was injected. The convulsion soon passed off, and the patient gradually recovered; it was full an hour before any pulse could be felt at the wrist, and she did not recover consciousness till the following morning. During that time stimulants were continually given; she remained for some time in a weak condition, but has since had another child, and is now doing well. The author then proceeds to analyse the table of cases, which shows, that out of 36 cases, 29 were recovered from imminent danger, and it does not appear that in the fatal cases death was due to, or hastened by, the operation. In two, it may be presumed that death had occurred before the operation was performed; in a third, only a small quantity of blood could be procured; in a fourth, no effect; in the fifth, there were marked but not permanent effects; in the sixth and seventh, the women were too much reduced to be restored. The author considers the influence of the blood injected not to arise from the mere mechanical effect on the heart, but from a direct stimulation of the nervous system, and that the rapidity of the effect is modified greatly by the circumstances of the case, as regards the previous duration and cause of exhaustion, and by the character of the means used, as regards quantity, quality, and the mode of operating. With regard to quantity, it appears, that a less amount was needed in proportion as the exhaustion arose from the suddenness, rather than the amount of the bleeding. The author thinks, that some cases have been lost from a fear of introducing too much blood, the dangers of which, he thinks, have been over-estimated. The quality of the fluid he regards as of great importance, and he alludes to the impropriety of using the blood of the lower animals. The blood need not be drawn from one individual only; that drawn from many may be taken, but it should be the blood of healthy persons. The want of success attending Dr. Simpson's cases of saline injection in uterine hæmorrhage he attributes to the nature of the fluid used, while the same fluid might be serviceable in cholera, where the quality as well as quantity of the blood is interfered with. With regard to the mode of performing the operation, the author believes, that a simple syringe, with a detached stop-cock, plated or tinned on the inside, and capable of holding about three ounces, is the best instrument. The more complicated instruments constructed to guard against the admission of air, he considers needless, as the danger is an imaginary one. In one case the operation was successfully performed with a common toy syringe. The operation should, however, be performed at the arm or in some distant vein, in preference to the neck, where there might be some risk from the entrance of air. The convulsions which arose in the author's own case, he attributes, not to any irritating quality in the blood injected, but to the transition of the patient from a state of coma to that of syncope; the same thing was noticed in one case three times on the exhibition of stimulants only, and before transfusion was performed. The author then proceeds to notice the opinions of writers on the subject of the treatment of uterine hæmorrhage, and concludes by making a few remarks on the general application of transfusion, which has been equally beneficial in cases of hæmorrhage from other causes, and in exhaustion from inanition. It has been, too, of temporary service in phthisis and in cancer of the stomach. Its use is suggested in the collapse of typhus and in the diarrhœa of children, where exhaustion is threatened.

Mr. Barlow desired to ask a question respecting the case just read. He had understood, that the beneficial effects had been produced by the injection of one ounce of blood. If that were all the blood used, it was, he thought, very surprising, that such an extent of rallying should follow the employment of so small a quantity.

The President remarked, that the author was not present, and therefore could not furnish the desired information. With respect to the smallness of the quantity of blood used, there were many cases alluded to in the table, in which also a small amount only was injected with beneficial results. The strange blood admitted seemed to have the effect of rousing the nervous energy and the heart, showing that it is not the quantity of the fluid, but the stimulus that is required. In other instances very large quantities of blood were transfused.

No other remarks being offered by the Fellows, the President applied to Dr. Robert Lee to furnish the Society with his opinion, and the results of his experience with respect to transfusion.

Dr. Lee had never seen transfusion of blood employed in any case of uterine hæmorrhage, nor could he place much reliance on it in any of the varieties of flooding; he did not believe that in the case before the Society the recovery of the patient could be referred to the introduction of an ounce of blood into the venous system. In accidental uterine hæmorrhage, if the membranes be ruptured early, and, that failing, if delivery be completed speedily by turning, the forceps, or craniotomy, and all the means in our power be employed to secure uterine contraction, comparatively few women will perish. He (Dr. Lee) had seen some recover where the symptoms were of the most alarming character, and recovery appeared absolutely impossible. In such cases, had transfusion been employed, the recovery would have been referred to it, and not to the real cause—the persevering and vigorous use of the ordinary remedies, pressure over the uterus, the external application of cold, and the internal administration of brandy, wine, and ammonia. In the hæmorrhage which takes place after the uterus has been wholly emptied of its contents, the same remedies, if actively employed, are successful in a large proportion of cases. In most of the fatal cases of this description which he (Dr. Lee) had seen, the common practice of introducing the hand into the uterus to excite it to contraction by rubbing the inner surface, had been employed; and he had also seen cases where fatal uterine phlebitis could be referred to the same plan of treatment, which does not succeed in exciting uterine contraction, when the patient is greatly exhausted from previous profuse loss of blood. This practice of rubbing the inner surface of the uterus with the closed fist, is not merely inefficacious in the worst cases of atony of the uterus, but it actually displaces the coagula from the exposed vessels which form one of the principal means employed by nature for the permanent suppression of the hæmorrhage. If proper compression be employed over the hypogastrium, coagula can never form to distend the uterus, and, like a foreign body, prevent its contractions. Hæmorrhage to a dangerous extent can never, he believed, take place where the uterus is contracted in the ordinary degree. The danger of uterine hæmorrhage from placental presentation is much greater than in the accidental variety; but the mortality had been very considerably diminished in his practice since he had observed the fact, that in rigid conditions of the os uteri it is possible to seize the lower extremities of the child with two fingers, and deliver by turning, without introducing the whole hand through the os uteri. It is deeply to be regretted, that an attempt, founded upon a grave anatomical blunder, should have been made to alter the practice established during the last century and a half in unavoidable uterine hæmorrhage. The blood does not proceed from the placenta, as has been asserted, and it is therefore irrational and absurd to recommend tearing it away, or detaching it from the uterus with an iron instrument, and leaving the child within the cavity after having imprudently deprived it of life. He (Dr. Lee) had great faith in the established rules of practice in all the varieties of uterine hæmorrhage.

ON THE OCCASIONAL ORGANIC UNION OF CONTIGUOUS TEETH.

By S. J. A. SALTER, M.B., etc.

(Communicated by THOMAS BELL, Esq., Sec. R.S.)

The object of this paper is to enumerate fresh examples of the so-called "bony" union of contiguous teeth; to explain the true nature of that union, as exhibited by microscopical scrutiny; and to suggest the probable mode of its formation.

1. The fresh instances here recorded are, a united dens sapientiæ and supernumerary tooth of the lower jaw; a cuspidatus and lateral incisor of the lower jaw united; and a specimen exhibiting the lateral and central incisors of the lower jaw in the same condition. These are particularly described.

2. In the next place, the nature of the uniting medium is shown to be dentine and not crusta petrosa, (as stated previously by writers on this subject.) This is demonstrated by microscopical drawings of sections of the teeth.

3. The probable mode by which this abnormity is produced is explained thus:—The pulps of the teeth form in their usual place and usual relation, with this one exception, that the portion of the capsule which should separate them is wanting. The result is, that they come in contact, and when the soft dentinal elements commence calcifying they unite, and the tubes of the two teeth become continuous. There is no enamel between the teeth where the crowns are in contact. The author further remarks, that all the teeth, and in both jaws, have been subjects of this peculiar condition. The paper concludes with a few practical remarks—that, in the majority of cases, the union could not be discovered while the teeth were in the mouth; and that, even where it could be discovered, both teeth must necessarily be removed together should extraction of either be required, as there appears no means of separating them.

Mr. Streeter would ask whether these teeth might not be examples of duplex formation, like the double uterus, etc., and not the result of union. The inscription on the drawing sent round certainly describes the teeth as the bicuspid and the incisor, but

they looked like a duplex formation, and he did not see why that process should not occur in the teeth.

A Visiter thought, that if such were the case, the regular number of the teeth would be imperfect, which did not in this instance appear to be the case.

MEDICAL SOCIETY OF LONDON.

JOHN BISHOP, Esq., F.R.S., President, in the chair.

APPARATUS FOR THE REDUCTION OF DISLOCATIONS.

Fig. 1.—Front view of Screw Extender.

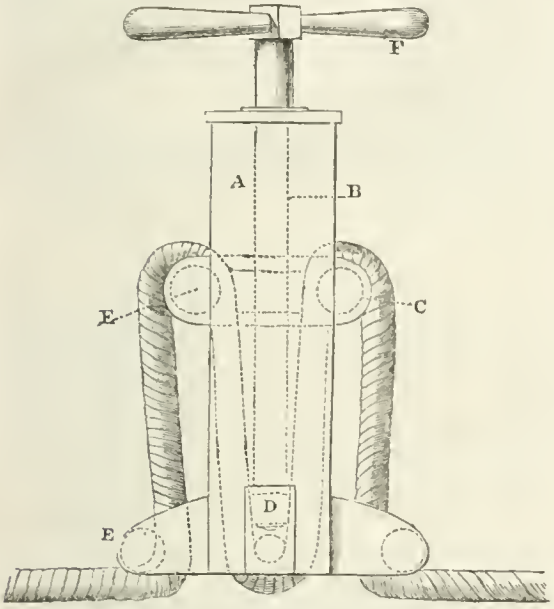

Fig. 2.—Side view of the Same.

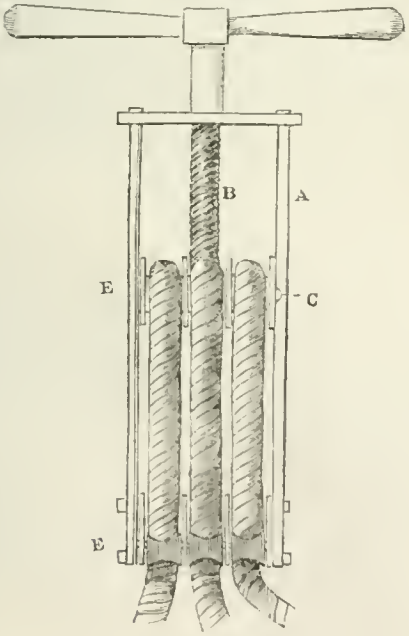
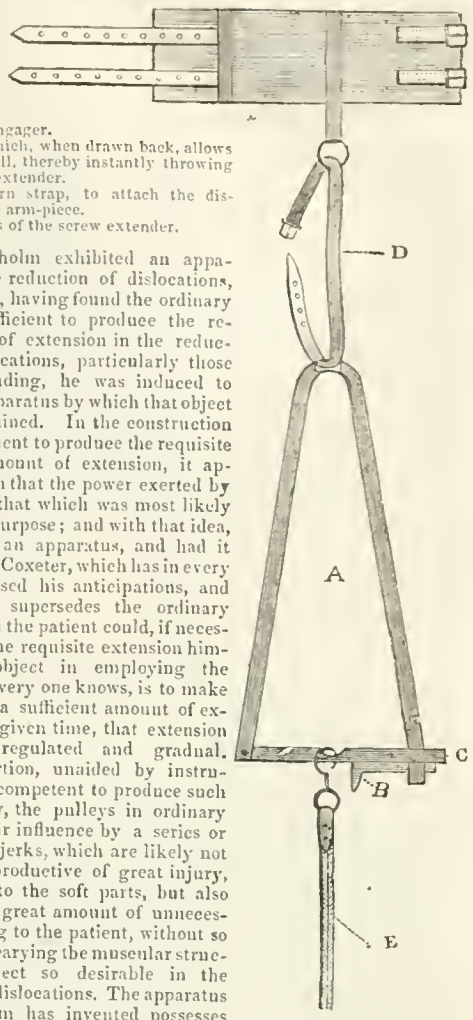


A The frame work.
B The screw.
C The movable piece with pulley wheels, over which the ropes play, and which ascends and descends on, and by the action of, the screw.
D The foundation piece, in which the screw works.
E Pulley wheels.
F Handle of the screw.



A The disengager.
B A bolt which, when drawn back, allows the bar C to fall, thereby instantly throwing off the screw extender.
D A leathern strap, to attach the disengager to the arm-piece.
E The ropes of the screw extender.

Dr. Broxholm exhibited an apparatus for the reduction of dislocations, and said that, having found the ordinary pulleys insufficient to produce the required kind of extension in the reduction of dislocations, particularly those of long standing, he was induced to devise an apparatus by which that object might be attained. In the construction of an instrument to produce the requisite kind and amount of extension, it appeared to him that the power exerted by a screw was that which was most likely to effect the purpose; and with that idea, he invented an apparatus, and had it made by Mr. Coxeter, which has in every respect realised his anticipations, and which quite supersedes the ordinary pulleys; even the patient could, if necessary, make the requisite extension himself. The object in employing the pulleys, as every one knows, is to make and keep up a sufficient amount of extension for a given time, that extension being well-regulated and gradual. Manual exertion, unaided by instruments, is incompetent to produce such effects. Now, the pulleys in ordinary use exert their influence by a series or succession of jerks, which are likely not only to be productive of great injury, particularly to the soft parts, but also to occasion a great amount of unnecessary suffering to the patient, without so effectually wearying the muscular structure—an object so desirable in the reduction of dislocations. The apparatus Dr. Broxholm has invented possesses great power of making extension, which can be well regulated, and made very gradually, and continued manual exertion is superseded by the ordinary power of the instrument itself. Very little force is required to produce an extraordinary degree of extension, and which, as before stated, when once made, can be kept up without the slightest manual interference. As will be seen from the accompanying illustrations, the length of extension will be four times that of the ascension which the screw, when turned to the right, causes the movable piece to make; consequently a very small apparatus is sufficient for the fulfilment of the intention; in fact, the apparatus possesses the power of the ordinary pulleys in an increased degree, without their objections, as well as the nicely-regulated action of the screw of the tourniquet. The next object to be effected, when the requisite degree of extension has been produced, and the articulating extremity thereby brought within due limits of the situation from which it has been displaced, is to suddenly disengage the extending apparatus, when the *tactus eruditus* will complete the reduction. Dr. Broxholm has added an appendage to the extending apparatus to carry out the above intentions, which will be seen from the illustration, with a description of its action. The apparatus was used successfully a week ago, when the ordinary pulleys had failed, in the reduction of a neglected dislocation of the humerus forwards, of between ten and eleven weeks' duration.

PARIS ACADEMY OF SCIENCES.

ON THE RELATIVE PROPORTIONS OF NUTRIMENT IN VARIOUS KINDS OF ANIMAL FOOD.

By M. MARCHAL.

M. MARCHAL communicated the results of his experiments, undertaken to determine the relative amount of nutriment in beef,

mutton, pork, veal, and fowl. He took twenty grammes of the muscular fibre of each of these animals, carefully selecting flesh free from cellular tissue and all fatty matter, except that naturally interposed between the muscular fibres, and evaporated them to dryness in a water-bath. The following table gives the results obtained:—

	First Experiment.		Second Experiment.	
	Solid matter.	Water.	Solid matter.	Water.
Pork	294·50	705·50	302·50	697·00
Beef	277·00	723·00	275 50	725·00
Mutton	265·50	734·50	263·50	736·50
Fowl	263·50	736·50	263·00	737·00
Veal	260·00	740 00	255 50	744·50

"It may be imagined," says M. Marchal, "from the above figures, that, as regards the nutritive powers of the above-named articles of food, they should be estimated in the order in which they stand. This conclusion, however, would not be correct, as those kinds of flesh in appearance the leanest, contain fatty substances which interfere with an estimation of the nutritive power properly so called. It is the muscular flesh that expresses real nutritive power, the fatty substances acting only as food for the respiratory organs, and not in the repair of the body. In order, therefore, correctly to determine the amount of nutriment in various kinds of food, it is necessary to eliminate these fatty substances from their solid residuum. This was done in the second experiment by treating the residuum, obtained in each case, with ether, until completely exhausted. The following were the results:—

	Matter soluble in ether.	Matter insoluble in ether.
Beef	25·437	249·563
Fowl	14·070	248·930
Pork	59·743	242·757
Mutton	29·643	233·857
Veal	28·743	226·757

Thus it will be seen, that in the order of their nutritive power the flesh of these animals must stand in the following order:—Beef, fowl, pork, mutton, and veal.

M. Magendie made some critical observations on the foregoing communication, which was sent to a Committee to be reported on.

At the annual public sitting held on the 22nd of March, the following were among the prizes awarded:—

Experimental Physiology Prize to M. Bernard, for his treatise on a new function of the liver in man and animals.

Medical and Surgical Prize of 2500 francs to M. J. Guerin, for his generalization of sub-cutaneous tenotomy. A sum of 2000 francs was awarded to M. Huguier, for his researches on the diseases of the female organs of generation. 2000 francs to MM. Briquet and Mignot, for their practical and analytical treatise on cholera. 2000 francs to M. Duchenne, of Boulogne, for his electro-physiological researches applied to pathology and thera-peutics. 2000 francs to M. Prosper Lucas, for his physiological and practical treatise on hereditary tendencies, both in a state of health and disease. 2000 francs to M. Tabarie, for having been the first to employ compressed air in the treatment of affections of the organs of respiration and other diseases. 2000 francs to M. Pravaz, for having elucidated, in the clearest manner, the influence of compressed air on the organs of respiration, on hematose, and the circulation, etc. 2000 francs to M. Gluge, for his treatise on pathological histology, and the application of the microscope to a detection of the alteration of the animal tissues. 1500 francs to M. Gosselin, for his researches on the obliterations of the spermatic ducts. 2000 francs to M. Garriel, for his applications of vulcanised Indian-rubber to medical and surgical purposes. 1500 francs to M. Vidal, of Cassis, for his invention of *serres-fines*, a kind of small clasp, by means of which, the edges of a wound, after operations, etc., are kept in contact better than by the use of bandages, plasters, sutnre instruments, etc. 1000 francs to M. Serre, of Uzes, for his researches on the luminous phenomena produced in the interior of the eye, by the pressure of that organ in particular directions and by various means. 1000 francs to M. Boinet, for his paper on the treatment of abscess by congestion, with iodine injections.

A prize of 2000 francs was awarded to M. Sucquet for his improved method of preserving bodies by the injection of an antiseptic liquid through the carotid arteries. This preservative liquid is prepared as follows:—A current of sulphurous acid gas is passed through a solution of carbonate of soda of the strength of from 20° to 22° Baumé, (sp. gr. 1·160 to 1·180,) until the whole of the carbonic acid is displaced, and the solution contains a slight excess of sulphurous acid. The fluid should then have a specific gravity of 1·200. It is next placed in a vessel containing clippings of zinc, and allowed to remain in contact with the metal until it has become sensibly neutral, the blade of a knife dipped into it not turning brown on exposure to the air. From four to six litres of this preparation are employed to inject a subject. After twenty-four hours, dissection may be proceeded with, and continued, without any inconvenience, for twenty, thirty, or even forty days. One of the great advantages arising from the employment of the sulphite of soda consists in the beneficial influence it exerts in cases of the accidents to which the operator is subject in the dissecting-room.

During the five years in which this preservative liquid has been employed, no fatal case has occurred.

A prize of 2000f. to M. Masson, for his process of preserving culinary vegetables by means of desiccation. These processes consist in first drying the vegetables, by the application of a moderate heat, in a stove, until a certain portion of the water has been driven off, and then submitting the dried substances to great pressure by means of an hydraulic press. The vegetables, thus prepared, when immersed in water, regain the greater part of the moisture contained by them previous to their desiccation, and, when cooked, are equal to fresh vegetables.

The summer course of cliniques of the Faculty of Medicine of Paris commenced with the beginning of April. M. Rostan and M. Roux at the Hotel Dieu, M. Piorry and M. Velpeau at la Charité, M. Nelaton at the Hôpital Clinique de la Faculté, and M. Langier at la Pitié.

MEDICAL NEWS.

Royal College of Physicians.—The President and Fellows of the Royal College of Physicians will receive distinguished literary and scientific persons at a *soirée*, on Wednesday evening, June 9.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 21st inst.:—

Carter, Vandyke Henry, Scarborough, Yorkshire.
Crosby, Thomas Boor, Gosberton, Lincolnshire.
Cunliffe, Robert Aulezark, Garstang, Lancashire.
Cusack, Samuel Athanasius, Dublin.
Davis, Maurice, Thame, Oxfordshire.
Foley, Samuel, Army.
Frost, Thomas, Hucknall, Forkard, Nottinghamshire.
Hurley, Michael, Dublin.
Lewis, Robert Benson, Trinity-square, Southwark.
Musson, William Edward, Birkholme, Lincolnshire.
Riddell, Andrew Nesbitt E., Aurungabad, East Indies.
Shout, Augustus Charles, Hampstead.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 20, 1852:—

Barnett, Barnabas, Shrewsbury.
Croudace, Thomas, Chester-le-street.
Gill, William George, London.
Richardson, Alfred, London.
Sankey, George, Ashford.
Sykes, John, London.
Wood, Alfred Stephen, London.

University of Oxford.—In a congregation, held on the 19th inst., the degree of M.D. was conferred on Barrington Chevalier, of Brasenose. The examination for the medical degree at Oxford takes place on the 15th of June. Candidates must transmit to Dr. Ogle, the Regius Professor of Medicine, the usual certificates of their having complied with the requisitions of the statute, on or before Monday, the 31st inst.

London University.—In our list of gentlemen admitted to the degree of M.D., in this University, the name of James Jones was accidentally omitted.

University of Dublin.—Dr. Samuel Gibson, who recently passed the examination for the diploma in Surgery instituted by the Board of Trinity College, has received intimation, from the Chief of the Medical Department of the Army, Dr. Andrew Smith, to hold himself in readiness to proceed to Chatham, preparatory to his entrance into the service as assistant-surgeon. This practical and spontaneous recognition of the value of the University diploma cannot fail to satisfy students and their friends of the nature of the surgical qualification of Trinity College.

Medical Appointments and Vacancies.—Mr. Sheppard has been elected house-surgeon to the Worcester Infirmary. Mr. Felix Clarke was also a candidate. The vacancy was caused by

the decease of Mr. Herbert Cole, to whose memory it is proposed to raise by subscription a monument in the cathedral. Both candidates were spoken of in the highest terms by the Governors. Mr. Sheppard obtained the election by a majority of 120. His father had performed the duties of surgeon to the infirmary for thirty-three years.

Military Appointments.—57th Foot: Acting Assistant-surgeon T. Clark Brady, to be assistant-surgeon, vice Jackson, promoted on the Staff. Hospital Staff: Assistant-surgeon James Jackson, from the 57th Foot, to be staff-surgeon of the second class.

Obituary.—On the 21st inst., in Barnsbury-road, William Webber, M.D., surgeon R.N., aged 34. On the 21st instant, at Star-hill, Rochester, John Lewis, Esq., surgeon, H.P., and in charge of medical stores, Fort Pitt, Chatham, aged 78.

Guy's Hospital.—Mr. Masterman, M.P. for the City of London, having placed at the disposal of the authorities of Guy's Hospital an assistant-surgeoncy in the Hon. East India Company's Service, the Examining Medical Council have conferred it on Mr. Wm. Burns Beatson, a student of the Hospital. This is the 2nd appointment within three years that Mr. Masterman has generously given to the authorities, to be awarded to the most distinguished among the pupils of Guy's Hospital, of which he is a Governor. It is an excellent plan for the disposal of such patronage, and cannot fail to be highly serviceable to the Company and to the Profession.

St. George's Hospital.—The appointment of assistant-surgeon in the service of the East India Company, given to the Medical School of St. George's Hospital by Sir Benjamin Brodie, has been accorded to Mr. George Naylor, one of the pupils. Mr. Pollock has placed a similar appointment at the disposal of this hospital.

The foundation-stone of the New King's College Hospital will be laid on the 17th of June next, at 1 p.m., by the Earl of Ellesmere. 14,000*l.* being still required to complete the estimated cost of the site, and of the contemplated buildings, the munificent Rev. Dr. Warneford, already so largely a benefactor to King's College, and to that known as Queen's College, Birmingham, has offered the additional sum of 500*l.*, to be paid as soon as nine other sums of an equal amount have been subscribed. Two of these have been already secured.

Medical Benevolent Fund.—As stated briefly in our last, the First Dinner of this Charity took place on Thursday, the 20th inst., at the London Tavern. The Earl of Carlisle, who presided, in proposing the toast of the evening, said: It is a toast relating especially to the business of this assembly—"Prosperity to the Medical Benevolent Fund." In introducing it, I labour under a difficulty by no means uncommon; I feel that, both from the obvious character of the undertaking, and also from the constitution of the present assembly, all that I could advance must be more vividly present to the minds of others than to my own, and be anticipated by them. Nevertheless, though for some reason or other I have often been called on to make after-dinner speeches for charitable institutions, I do feel more than a usual desire not to be wanting to the present occasion. This may arise from my feelings of regard to the gentleman who enlisted me—Mr. Toynbee, and partly from the intrinsic merits of the undertaking; and partly, also, from the fact of this being the first celebration of the founding of the Institution. (The noble Earl then gave a brief outline of the history of the Fund, expressing a hope that it had now taken permanent root, which could hardly be questioned by any who saw the details of the cases which had been relieved. He then read from the Report the particulars of several cases in which the Institution had afforded relief, and proceeded:) The deep tragedies of such cases must speak more forcibly to your hearts than any rhetoric which I could bring to bear on them. I know, gentlemen, that it has been thought, that our efforts ought to be directed to prevention rather than to palliation, and that prudence and caution ought the rather to be cultivated in respect to these evils and calamities. Now, I do not mean that this principle should be left wholly out of view; but I am convinced that it cannot be rigidly applied in a world like ours—steeped in so much misery, and misery brought about by events over which we can exercise no control. Take, for instance, the circumstances of your own Profession. The rolls of that Profession include a large list of young practitioners fresh in the practice of their calling, and with far more of ardour and devotedness than of money in their purses. We know well, also, that there is scarcely a street or alley which is not rife with pestilence and corruption, and scarcely a gale which is not tainted with disease and death for some. Under such circumstances, the voice of duty speaks positively to the medical practitioner as to the soldier in the very shock of the battle. The voice of duty says:—"You, too, must go into the front ranks of danger—you must descend into the harvest of death—you must inhale the breath of corruption—you must encounter all that is most loathsome and revolting in nature." I feel sure, that none of you shrink any more from duty than do the bravest of our sailors or the boldest of our soldiers. But the soldier has his Chelsea—the seaman has his Greenwich, and the yearly budget is laden with the dead weight of pensions. But for you, whose Profession it is to save life—whose privilege it is to repair and not to inflict the ravages of violence and crime—for you, the national gratitude provides no asylum, secures no relief, awards no compensation. Well, then, what the gratitude of the nation has prevented, and what the national gratitude does not offer, it devolves on you and on us to do; and those on whom this duty devolves may be separated into two classes—medical men, and others. With respect to the former, I would appeal to those of long standing and of considerable reputation, to do it from motives of sympathy and generosity; and I would call on those who may not as yet have been altogether successful in their calling, but who are still struggling, to do it, so that, in their hour of need, they may have furnished for themselves the best of all pleas for assistance; but on one and all I call on to do it, because you belong to a Profession which has always appeared to me to have something godlike in it. It was deemed so in the Homeric era, and is as strikingly evidenced when we read of the divine Polybius; and surely it is not less so now, when, if any, it proved itself to be the Profession of all others sanctioned by the Divine Author of our faith. And then, if there be something godlike in it, I shall not call on you in vain to carry a savour of that divinity into all your actions. To those who do not belong to the Profession, I think we should all of us lay it to heart how little we know when the fatal stroke—when the death-blow will come upon us; and if we would do justice, and afford due encouragement to the skill and ability of those who can then be the only instruments in suspending the uplifted blow and prolonging the precious hour in the balance—hours for which we should be ready to lavish our treasures and life itself,—if we would endue them with the proper motives to be our saviours, then it belongs to us to do while we have the opportunity—to do all we can in support of such a noble Institution. I beg to propose the toast, coupling with it the name of Mr. Newnham.—The toast having been drunk with honours, and Mr. Newnham having acknowledged the honour in a speech which was very indistinctly heard, Mr. Toynbee, Treasurer to the Dinner-fund, read the first list of donations, etc., in doing which he paid a handsome tribute to the self-denying and unwearied exertions of Mr. Newnham—to whom they owed a great debt of gratitude; and also to Mr. Churchill, who, with his accustomed liberality, had placed at the command of the Committee one of his rooms in London, besides being one of the most active members of that Committee. Dr. Burrows was also mentioned in grateful terms, for his exertions in collecting for the funds—to whom a first list, amounting to 157*l.*, was due. The President next proposed "The Royal College of Physicians," coupling with it the name of Dr. Seymour; and in succession "The Royal College of Surgeons," with the name of Mr. South. The other toasts were, "The Provincial, Medical, and Surgical Association, in which the Fund originated, and Sir C. Hastings;" "The Worshipful Society of Apothecaries, and Mr. Eyles;" "The Society for the Relief of Widows and Orphans of Medical Men, and Dr. Burrows;" "The British Medical Fund, and Dr. Forbes;" "The Medical Benevolent College, and Mr. Propert." Dr. Conolly proposed "The Provincial Benevolent Fund;" and Sir James Clark having, in an eloquent and feeling speech, proposed the health of the noble Chairman, Lord Carlisle replied and retired; previous, however, to his doing so, Mr. Toynbee read the second list of subscriptions, and announced that the total amount subscribed was more than 500*l.*

Medical Society of London.—The reading of Dr. Cormack's paper, which was announced in our last Number for this evening's meeting, (the closing one of the session,) is prevented by the unavoidable absence of that gentleman from town.

The Convalescent Fund of St. George's Hospital.—The box at the corner of St. George's Hospital, for the deposit of gifts in aid of the Convalescent Fund—the touching inscription of which is the object of so much attention—has just received a donation of 20*l.* from Lord De Blacquire, the owner of the yacht America, now cruising in the Mediterranean. His Lordship, in a letter to Dr. Wilson, states, that "it is the product of a Charity-tax of one pound each," which he has inflicted upon friends who have sailed with him; and he trusts, that the publicity given to the fact will induce other owners of yachts to do likewise.

The Metropolitan Interment Bill.—Lord John Manners moved, on Friday night last, for leave to bring in a Bill to amend

the law concerning the burial of the dead in the Metropolis. The Bill has two objects; one, to close the burial-grounds in the Metropolis; the other, to empower parishes to create cemeteries and burial-grounds outside the Metropolis, to receive the bodies for which the intramural burying-grounds cannot find room. This Bill is in direct opposition to that carried by the Board of Health, but which, through the omission of one clause relative to rating, was found inoperative.

The London Necropolis and National Mausoleum Bill was read a third time and passed in the House of Commons, on Friday night. (This is the Woking scheme.)

M. Chomel.—Politics affect even the peaceable science of Medicine. M. Chomel, the celebrated Parisian physician, having refused to take the oath to the President, required by the *quasi*-Constitution, has vacated his Professorship at the College of Medicine.

A medical man in Breslan has been fined 40 thalers for having neglected to attend to a patient who sent for him. (!)

Progress of Epidemics. — The small-pox is spreading in Jamaica. In the parish of St. Anne, where it had only been prevalent two or three weeks, there were upwards of 4000 cases. The greatest destitution prevailed, and, in many instances, poor persons perished for the want of assistance and of medical care. In Kingston there are several cases. The cholera, which was lately reported to be exceedingly fatal in Bokhara, is now stated to have broken out in some places in Upper Silesia, a part of the Prussian kingdom, where great misery prevails. If this be really the case, and it should extend, as it will in all probability, the mortality will be dreadful, for the dearth and misery in many parts of Germany have, of late, been on the most fearful scale, so that the bodies of dead dogs, in a semi-putrescent state, have been devoured by the starving inhabitants.

Patent Agency.—In consequence of the death of the late Mr. R. W. Urling, the patent agency business, lately carried on at 19, Rue de Brabant, Brussels, will be continued on the same footing as before, in the name of Urling and Co., the acting partner being Mr. William Henry Kirkpatrick. We beg to recommend the firm in all patents bearing on the Medical Profession.

TO CORRESPONDENTS.

We have to intimate that, in future, all Communications for this Journal must be authenticated; gentlemen, therefore, who address us must favour us with their names,—certainly not for publication, but that we may be satisfied of their good faith. Henceforth, then, it is to be understood, that, when a letter is unnoticed, it is because the writer's card did not accompany it.

Gentlemen desiring personally to communicate with the Editor, on the business of the Journal, will find him during the Summer Months, on Tuesdays, Wednesdays, and Thursdays, between the hours of 12 and 2, at the Office, 46, Princes-street, Soho.

It is again requested that communications SHALL NOT BE OTHERWISE addressed than

To the Editor,
"Medical Times and Gazette" Office,
46, Princes-street, Soho,
London.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have read with much interest, in your Number of May 8, p. 473, some observations made by Professor Bennett on the exhibition of quinine in typhus and typhoid fevers. Dr. Bennett stated, that in none of the cases treated by him did the quinine shorten the disease, or in any way favourably influence its progress; but he says that the experience of other physicians had been more favourable. Dr. Graves, of Dublin, for example, had written to Dr. Dundas to that effect, &c. &c. My present object is to state, that there must be some mistake with regard to my experience, as I have never had an opportunity of testing the efficacy of the method of treatment recommended by Dr. Dundas.

Dublin. I am, &c. Robt. J. Graves.

We are unwillingly obliged to decline the communication of "M.D., and an Admirer of Religious Freedom."

Allopath will be published as soon as possible.

E. A.—Mr. Wiblin, of Southampton, has published (Renshaw) a work on the Parisian schools, to which we refer our correspondent.

No such "Students' Magazine" as our correspondent suggests, could exist more than a session.

A Subscriber.—We believe not. The subject is very nasty.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have lately been consulted by a gentleman for a varicose state of the veins of the penis, especially of those on the dorsum. When he first perceived it, two or three years ago, he derived temporary benefit from the use of some lotion. As such an affection is not alluded to in any work on surgery to which I have access, I shall be obliged if you or one of your Correspondents will suggest a remedy to An Inquirer.

[To the Editor of the Medical Times and Gazette.]

Sir,—As Mr. Sibley is not satisfied with Mr. Ward's experiments on the clavicle, and as he thinks those experiments do not explain why the bone was dislocated and not fractured, let us again turn to the case as reported by him. I have not a copy of your Journal with me to refer to, but I think it was stated that the injury was caused by a horse having planted its hoof on the girl's clavicle. Here, then, without calling in the aid of experiments, is, I think, sufficient cause to explain why the bone was dislocated and not fractured. A horse's hoof being nearly as long in the transverse direction as the clavicle, it would press on nearly the whole length of the bone. Again, the clavicle being a bone which has little to support it behind, and the ligaments which support the sternal end being less strong than those which support the acromial end of the clavicle, I conclude the bone must either have been dislocated or crushed. I leave it to Mr. Sibley to decide whether the bone were more likely to have been crushed than for a ligament or two to give way. I am, &c.,

A St. George's Student.

P.S. I must also beg to inform Mr. Sibley that the experiments of Mr. Ward do not demonstrate the strength of the clavicle (as stated by him), but the elasticity of that bone. I think he will come to the same conclusion, if he carefully reads Mr. Ward's experiments.

We dare say that Dr. Foote's proposed work on Lunatic Asylums will be very useful.

[To the Editor of the Medical Times and Gazette.]

Sir,—In your Notice to Correspondents, I shall be obliged for your opinion to the following:—

I attended a lady with peritonitis, and paid every attention. She recovered completely. Ten days after, from some imprudence in diet, had an attack of pain in the abdomen, arising from spasms, through irritation. I was sent for, and prescribed. Because she was not immediately relieved, sent for another medical man, without first mentioning it to me. I sent immediately my account, and declined attending her any longer after such treatment. Did I act professionally or not in the matter? I am, &c.

A Constant Subscriber.

[Perfectly professionally, as far as we can judge from the facts before us.]

COMMUNICATIONS have been received from—

Dr. Smith, of Cheltenham; Mr. Newnham, of Farnham; Dr. Maddox, of the British Seaman's Hospital, Constantinople; Dr. James Jones, of Judd-street; A Constant Subscriber (unauthenticated); Mr. Burford Norman, of Duchess-street, Portland-place; J. T., Edinburgh (unauthenticated); M. D., and An Admirer of Religious Freedom; E. A.; Messrs. ORIGINAL LECTURES.

CLINICAL LECTURE

ON AN

ERYSIPELATOUS AFFECTION OF THE THROAT,

DESTROYING OR GREATLY IMPAIRING THE POWER OF DEGLUTITION.

DELIVERED AT

King's College Hospital.(a)

By ROBERT B. TODD, M.D., F.R.S.,
Physician to the Hospital.

Gentlemen,—I shall beg your attention to-day to the particulars of an extremely interesting case, an affection of the throat, which interferes very much with the act of deglutition. The affection is a rare one, and, so far as I know, has escaped the notice of systematic writers. The case which I am about to bring before you is, therefore, the more deserving of your attention, and especially as it is a a good example of a disease of which I have myself seen only four other cases. The disease is of a very fatal tendency, if not at once treated with great decision. On this account it is of the last importance that you should immediately recognise it, as delay in the adoption of suitable treatment may be fatal to the patient. The cases are, if I may so speak, of the kill or cure class; the symptoms last but a short time, and the disease runs its course, whether for life or death, in a brief period.

The patient is a man named George King, in Sutherland Ward, aged 64; he is tall, and of spare build, and he looks much older than the age he gives, and appears as if he had been suffering for some time from illness. This condition, he tells us, results from a severe attack of rheumatic fever, under which he suffered about a year and a half ago, which was accompanied with cardiac affection.

Since that attack, he has been more or less an invalid, from a succession of catarrhal affections up to Friday the 26th of April, 1851, on which day, while he was crossing St. James's-park, he was suddenly seized with a sensation as if something had forcibly closed his jaws, and he found, to his alarm, that he could not open his mouth with the most violent effort. The affection at the same time seemed to attack the throat, and completely to prevent his swallowing. When he arrived at Pimlico he could not speak distinctly; he could not eat any dinner, and was unable to swallow some gin and water which he attempted to take. He could get it into his mouth, and it even reached the pharynx, but would go no further; it seemed, to use his own expression, "to stick in his throat," and was soon returned. He made frequent and ineffectual attempts to swallow, but, from this time till the following Tuesday, he remained without taking a particle of nourishment.

When he was admitted into the hospital, attempts were made to examine his throat, but, in consequence of the state of trismus which prevailed, the teeth could not be separated sufficiently far apart to admit of any examination being made. I will read you the following extract from notes made at the time of his admission, by Dr. Salter, the house-physician:—"On attempting to look into his mouth, I found I could not separate his jaws more than about one-eighth of an inch,—just a chink. I gave him some water, which he attempted to swallow. He performed the buccal and lingual, and, to a certain extent, the pharyngeal part of deglutition, but then, with a spasmodic effort to get it further, he choked, his eyes looked as if they would dart from his head, and up it came. Repeated attempts merely led to repeated failures. I could neither look into his throat, nor insert my finger to feel it."

When I saw him, on the afternoon of the same day, I found just the same state of things,—deglutition quite impossible, the attempt to swallow followed by the forcible ejection of the food through the mouth, and in some degree through the nostrils, by a spasmodic expiratory effort.

In considering what might be the affection calculated to give rise to these symptoms, I first thought of stricture of the œsophagus; but, upon inquiry into the history of the case, it seemed very unlikely that the difficulty of deglutition could arise from this cause. The affection came on suddenly, which is not the case in the ordinary stricture of the œsophagus. Stricture of the œsophagus generally results from cicatrization of ulcers and contraction of the tissues adjacent, and such strictures are most apt to occur in the lower part of the tube not far from the cardiac orifice. Did such a stricture exist, the dysphagia would have been of a different kind. Here matters were suddenly and forcibly rejected, while, in the former condition, the food is swallowed to a certain point, and seems to encounter an obstacle at a certain situation, to which the patient points with his finger; then it is either stopped completely, and afterwards ejected, but not with the force and rapidity which we observed in this case, or, by a considerable effort, it is made to overcome the obstacle. A spasmodic state of the œsophagus might create a dysphagia like that noticed in this case; but the symptoms would scarcely have come on so rapidly, nor would the danger of choking have been so imminent, as in our patient. It seems to me, that the seat of obstruction or difficulty was not so low as the œsophagus, but rather in the pharynx, and that the food encountered it immediately on passing from the mouth.

Difficulty of deglutition sometimes results from an affection of the medulla oblongata, but here it is produced by paralysis of the nerves which arise from the medulla and supply the pharynx, such as the vagus, or glosso-pharyngeal. In such cases, the dysphagia does not come on suddenly, and would not be accompanied by the acute symptoms present in this case. Aneurisms, again, frequently give rise to dysphagia. Difficulty of deglutition is often a most important diagnostic mark of thoracic aneurism; but this, of course, comes on gradually, as the dimensions of the aneurismal tumour increase.

Another cause to which we might refer these symptoms is, inflammation of the epiglottis, which is capable of producing great difficulty of deglutition; and, if we bear in mind the position of the epiglottis, we shall not be at a loss to conceive how this takes place. If the epiglottis be enlarged, it lies as a tumour between the rima glottidis and base of the tongue, and would not only form some degree of obstruction to the passage of the food down the pharynx, but it would prevent that perfect apposition of the root of the tongue to the rima glottidis which is necessary for the perfect closure of that chink. When the epiglottis is diseased, the difficulty of swallowing arises from the tendency of the food to pass into the larynx, the effect of which is, a violent spasmodic action of all the muscles of the part, and the food is forcibly projected upwards into the posterior nares. Thus this peculiar mode of regurgitation of the food becomes a most valuable point in the diagnosis of a diseased state of the epiglottis. For you will always find, that, where difficulty of deglutition arises from an inflamed or ulcerated state of the epiglottis, the food is thrown upwards into the nose, and is frequently forced out at the nostrils with considerable violence. In the present case, no such condition existed; the food was chiefly rejected through the mouth; only a small portion of it could have passed through the nostrils; but, to any one witnessing the man's attempt at deglutition, it was plain that the dysphagia was very different from that which characterises disease of the epiglottis. Moreover, in disease of the epiglottis, there is more or less of affection of the voice. In our patient that function was not impaired. Hence I was led to exclude epiglottidian disease from my diagnosis.

Again, it might have been a case of common cynanche tonsillaris. If we could have opened his mouth, this point might have been decided at once; but the complication of trismus hindered our efforts at diagnosis very much. However, I decided against cynanche tonsillaris upon the suddenness and force of the rejection of the food. In cynanche, the deglutition is extremely difficult and painful, and made with great effort and suffering; but it is not impossible, nor is the rejection of the food made in that violent, sudden way which we observed in this case, nor with the signs of choking.

If, then, there was no cynanche, no stricture, no laryngeal or epiglottidian disease, no aneurismal or cerebral affection, what could have caused this remarkable dysphagia?

When I had examined the patient, the existence of certain cases was brought forcibly before my mind, and I felt certain that the peculiar symptoms in the present instance resembled those which I had observed on some previous occasions with great interest. Four of such cases I have now seen. The

(a) Lecture XXXI., May, 1851.

first occurred to me many years ago in private practice. I was called to see a lady who had for some days been suffering from influenza. The principal affection, however, was great difficulty of deglutition. When she took any food, it evidently reached the isthmus faucium, but there it seemed to excite choking, in consequence of a portion apparently passing into the larynx, whence it was repelled with considerable force; so urgent was this difficulty of swallowing, that it was impossible to give her food, for fear of producing suffocation. When I looked into her throat, I saw that there was no mechanical impediment to the passage of the food into the pharynx; and all that I could observe was slight redness of the velum, and the mucous membrane of the pharynx was of a dusky hue. I found, also, that no amount of stimulation of the mucous membrane of the velum would excite contraction of the palatine or pharyngeal muscles. Believing that the phenomena depended upon an inflamed state of the mucous membrane of the throat, and not having yet learned that the proper antiphlogistic in such cases was support and nourishment, I was content to trust to leeches and blisters to the throat. But my patient became more exhausted, and rapidly sank.

The second case occurred in the person of a middle-aged woman, the wife of a respectable tradesman in Westminster. I had no difficulty in immediately recognising the similarity to the former case. The symptoms were just the same. If fluids were given they ran down into the larynx, and were expelled with cough; and any mechanical stimulus failed to excite contraction of the velum. There was dusky redness of the velum and pillars of the palate. Profiting by former experience, I determined to exclude all depressing treatment in this case. I ordered injections of strong beef tea with ten grains of quinine to be given every four hours, and I freely applied the solid nitrate of silver to the fauces. The injections were given regularly, and the next morning I found my patient much better. She could swallow a little, and appeared stronger. I now ordered her to take beef tea and wine cautiously by the mouth, in small quantities at a time, and the quinine was also given by the mouth. In less than forty-eight hours more she had completely recovered.

The third case was that of a gentleman of fortune, whom I attended at one of the hotels in my neighbourhood, in the month of March, when erysipelas was rather prevalent about town. The symptoms under which he laboured were very similar to those which I have just detailed in relating the other cases. There was great difficulty of deglutition, but he had some power of swallowing; there was also the same tendency for fluids to pass into the larynx; the muscles of the palate showed the same want of contractile power. The mucous membrane was of the same dusky red hue. This patient was treated by support and stimulants, and the local application of nitrate of silver. As he was in affluent circumstances I gave him turtle soup and port wine and quinine. He got quite well in two days.

Not long since I was called to see a woman who was suffering from symptoms of the same character. In this, as in the other cases, it was impossible, by any amount of stimulation to excite contraction of the muscles of the soft palate; and if we administered a small quantity of fluid, it ran down into the glottis, causing violent irritation and choking. She had been ill some days, and had been treated by leeching, blisters, and mercury, as in my first case, and was in a state of extreme exhaustion when I saw her. The isthmus was quite open, and there was no impediment to deglutition except the paralytic state of the muscles. This patient died after an illness of two or three days: she died, indeed, while I was in the house.

This was the fourth case, and the patient now under treatment is a fifth. You see that they are all very serious cases, and that I am justified in calling them kill or cure cases, so brief is the period of their duration, whether for weal or woe; and although they are rare cases, you will I am sure appreciate the importance of being prepared for them, so that you may not be at a loss if perchance one should fall to your care. Though these are formidable cases to witness, and run their course very rapidly, terminating in death or recovery within forty-eight hours, they are, I believe, if taken soon enough, perfectly amenable to treatment, and I feel persuaded that the first case which I described would have recovered if she had been treated on a different plan. At the time that it occurred to me, I was not familiar with the symptoms—I was not "up to the disease," if I may so express myself; and I hold the opinion, that such cases would almost always recover if subjected to proper treatment before extreme exhaustion had come on.

Now, believing that our patient up-stairs was suffering in the same way as those other patients whose cases I have related, I put him on the same treatment as that which I followed in the successful cases. Ten grains of quinine, diffused in two or three ounces of strong beef-tea, were administered every four hours, in the form of an enema. I should have also ordered the nitrate of silver to be applied to the throat, but that the state of trismus prevented his mouth from being opened.

On the following day, he was very much better, and his mouth could be opened to the extent of half an inch, and he could swallow a little liquid.

On the 30th, he could open the mouth sufficiently to enable Dr. Salter to examine his throat; and then, although considerable progress had been made towards recovery, the mucous membrane of the upper and back part of the pharynx was found of a purplish, dirty-red colour, indicating, as I thought, the existence of a low erysipelatous inflammation. There was no swelling of the mucous membrane, and no mechanical impediment to the passage of food into the pharynx, but the velum did not contract freely, as it does in health, upon the application of a mechanical stimulant. This condition of the velum depends upon one or both of two causes, viz., upon a benumbed or paralysed condition of the sensitive nerves of the pharynx, through which its muscular action is usually excited by the contact of the food; or upon the extension of the erysipelatous state to the muscles of the part, and a consequent paralysis of them.

The case of our patient King differed remarkably from the others, in being complicated with a state of trismus; which condition, however, I think admits of explanation, on the supposition that the principal source of irritation was the throat. If you call to mind the presence of the extensive nervous plexus lying outside the tonsils and isthmus of the fauces, which is called the pharyngeal plexus, and consider how this is formed, you will not be at a loss to account for this symptom. The pharyngeal plexus, as you know, is made up of fibres from the vagus, glosso-pharyngeal, and sympathetic nerves.

Irritation of theramifications of the two former nerves may be readily propagated to the medulla oblongata, so as to affect the motor portion of the fifth nerve, which is implanted there, and by which a convulsive state of the muscles of mastication may be excited and maintained.

Our patient, as I have said, recovered to a slight extent his power of swallowing the day after his admission into the hospital, and was able to open his mouth slightly. We now discontinued the quinine injections, and gave him wine and nutritious food, and quinine by the mouth. Under this plan, his power of deglutition was completely restored in two days; but there remained a catarrhal state of the mucous membrane of the trachea and large bronchial tubes, for which he was kept some days longer in the hospital.

Now, that this affection of the pharyngeal membrane was of the erysipelatous kind, I think I was justified in affirming, from the following considerations: 1. From the rapid invasion of the attack, and the great constitutional disturbance with which it was accompanied. 2. From the local redness; and 3. From the great prostration with which the attack was rapidly followed, which was sufficient to kill two out of five cases. Our patient King, as well as all the others whose cases I related to you, seemed to succumb at once under the influence of some powerfully depressing poison, just as patients attacked with external erysipelas do. Then, it is well known, that cases of erysipelas of the head and face often commence with sore throat, or that there are a soreness and redness of the fauces simultaneously with the appearance of the first patch on the face.

The marked difference in the treatment of the successful and of the fatal cases, likewise favours the opinion, that the affection was erysipelatous in its nature. The two fatal cases were treated by a depletory and depressing plan; the three successful ones by a supporting plan, which consisted in, first, the careful avoidance of everything tending to produce fatigue, or exhaustion, or depression; secondly, in the frequent administration of quinine in large doses, in beef-tea in the shape of enemata, and afterwards, when the power of deglutition returned, the exhibition of bark, ammonia, wine,

etc., according to the circumstances of the case; thirdly, in the local application of the nitrate of silver to the throat.

The erysipelatous character of the affection is further indicated by its extension to the trachea and bronchial tubes, giving rise to the bronchitis under which the patient subsequently suffered, and from which he is now recovering, having been subjected to a similar course of treatment to that at first adopted.

ORIGINAL COMMUNICATIONS.

CASE OF ACUTE RETINITIS, WITH REMARKS.

By ROBERT TAYLOR, M.D.,

Physician to the Central London Ophthalmic Hospital.

Mrs. Callaghan, aged 35, the wife of a cabman, applied at the Central London Ophthalmic Hospital, on the 10th January, 1852.

Two days previously, while walking along the street, she felt a sudden, severe pain in the left eye, as if she had been struck by a sharp-pointed stone; the pain continued and increased; in a few hours the right eye was similarly affected, the sight rapidly failed, and in the course of the same evening she was in a state of almost total blindness, and great agony. She took a couple of purgative pills, which acted freely on the bowels, and bathed the eyes with cold water, which gave slight relief.

She complained of intense, deep-seated pain in both eyeballs, darting to the top and back of the head; constant, but varying in severity; a feeling of tension in the head and eyes as if they were about to burst; excessive tenderness of the eyeballs and of the whole of the front of the head, so that she screamed out at the slightest touch; constant luminous and prismatic-coloured spectra, in the form of large rings; intolerance of light to such a degree that she could not bear to turn her closed eyes to the window, though the day was dull and foggy; constant spasmodic twitching of the muscles of the eye, which added greatly to her suffering, as the slightest motion was attended with pain. In the right eye vision was totally extinct; with the left, she could just discern large objects, as through a dense fog. She had had no rest since the commencement of the attack, and was worn out with pain and want of sleep.

The right eyelid was slightly red and swollen. With her back to the light, she could for an instant expose a very small portion of the left conjunctiva, which was moderately injected, but the iris was invisible, and the right eye could not be opened at all. The excessive tenderness and photophobia prevented any further examination. Her pulse was rapid and weak, and her tongue clean.

I ascertained that she was a woman of dissipated habits, and that she was seldom for more than a week or ten days free from a black eye or a bruise on the head, inflicted by her husband in their drunken quarrels.

℞ Hydrarg. c. cretâ, ext. conii. aa. gr. iiss. Ft. pil., ter in die sumend.

Unguent hydrarg. c. opio, temporibus infricandum; lotio belladonnæ.

She was directed to darken the room, to remain in bed, and to apply cold water so long as it afforded any relief.

12th.—Slight tenderness of the gums, and strong mercurial fetor of the breath. The pain was less severe, and she had slept a little during the night. With the blinds down, and the eyes turned from the window, she could for an instant expose the left pupil. It was about half dilated, and perfectly regular in form. A glimpse was also obtained of the conjunctiva of the right eye, which was more vascular than that of the left. During the first few days, she found relief from cold applications, but now cold increased, while warmth relieved, the pain.

13th.—Mouth sore and sub-maxillary glands swollen; great relief from the pain and photophobia; the luminous rings had also ceased, and were succeeded by frequent flashes of light, especially on moving the eyes; vision improved; pupils moderately dilated and regular; irides, so far as could be made out, free from inflammation.

Capiat pil. i. omni nocte; magnes. sulph. ℥ss. statim.

15th.—Vision so much improved that she could see small objects at the opposite side of the room, but as if through a thick fog, especially before the right eye, which was all along more severely affected than the other. She opened both eyes without difficulty. There was a very faint pink zone around the cornea, so slight that it could scarcely be perceived without a lens; irides of a light hazel colour, and free from the slightest appearance of disease; pupils well dilated, and of a clear black colour.

Contin. pil. omni nocte; capiat pulv. cinchon. et sodæ ter in die.

23rd.—Vision perfectly clear, but the eyes were weak, and could not be used for more than a few minutes at a time on minute objects. Slight tenderness of the right eyeball, and a little chronic inflammation of the lids. The mercury was discontinued on the 18th; her mouth was now well, and her strength improved.

February 4.—Two days previously the recovery was almost perfect, when a premature recurrence to the gin-bottle brought on a slight return of dimness and pain.

Emplastra lyttæ temporibus; contin. pulv. cinchon. et sodæ.

7th.—The symptoms were again subdued, and, with the exception of slight chronic inflammation of the lids, the eyes were perfectly well.

I saw her again about a month afterwards, and found that her vision was perfect in every respect, and her general health completely restored. The inflammation of the lids had been removed by a slightly astringent lotion.

Remarks.—Diseases of the eye, not being of themselves fatal, we have rarely an opportunity of making a *post-mortem* examination where the morbid process has been still in a state of activity at the period of death; we can only trace the effects of previous disease, often with a very imperfect account of the symptoms by which it has been accompanied during life. Hence the pathology of the deep-seated tissues of the eye is, to a considerable extent, conjectural; and we find the greatest discrepancy in the opinions of authors as to the precise pathological value to be attached to the groups of symptoms which are combined in various forms of what is comprehensively termed amaurosis.

The chronic and subacute affections of the retina have been especially elucidated by the labours of Mr. Lawrence, Mr. Tyrell, and Dr. Jacob; but considerable confusion appears still to prevail with regard to acute inflammation. The term "acute retinitis," is applied by several of our best authors, for example, by Dr. Mackenzie and Mr. Tyrrell, to that form of disease in which the whole contents of the globe are simultaneously involved, and to which the term "ophthalmitis interna," originally proposed by Beer, appears to be much more appropriate; that form in which the inflammation is limited exclusively to the retina, and to which alone the term "retinitis" applies, has been by them entirely overlooked, or, what is more probable from the extreme rarity of its occurrence, has not been observed.

The recorded cases of simple acute retinitis are exceedingly few in number; others may probably exist, but I have only succeeded in discovering two in which the conditions of acute inflammation and absence of complication are combined. One of these is recorded by M. Cunier, in the "Annales d'Oculistique," Suppt., Vol. 1.; and the other, which occurred in the practice of Mr. White Cooper, is given in the *Lancet* of 1844. In both of these cases, the symptoms and appearances exactly resembled those of the case above detailed, and seem to afford sufficient warrant for preserving the distinction which has been drawn between the two diseases. These symptoms can be satisfactorily explained only by referring the seat of the disease to the retina, while the clearness and unaltered form of the pupil, and the absence of any discoloration of the iris show that the other tissues could not have been engaged to any appreciable extent.

The researches of Professor Van der Kolk as to the peculiar arrangement of the blood-vessels of the interior of the eye, throw considerable light upon the pathology of these obscure affections, and seem to explain how inflammation, especially of a chronic character, may remain confined to the retina for an indefinite period; whereas, when it attacks the iris or anterior chamber, this tunic is generally, to a greater or less extent, involved.

The retina is supplied by the arteria centralis retinæ, which breaks up into numerous ramifications, forming a fine capillary plexus which terminates in a marginal vessel just within the ora serrata. Here it was formerly supposed that its connexions ceased, and that the retina was thus cut off from any vascular communication with the rest of the eye; but Professor Van der Kolk has succeeded in demonstrating a set of very minute vessels which pass off from the vascular wreath formed in the zonule of Zinn by the terminations of the ciliary arteries, to supply the hyaloid body and the anterior capsule of the lens, and to communicate with the vessels of the retina. This vascular circle, therefore, in the zonule of Zinn, forms a bond of union between the choroid, iris, capsule of the lens, retina, and hyaloid body; it is in the very focus of inflammation when this attacks the anterior parts of the eye; so that the various communicating vessels necessarily participate in the increased action, and convey the disease, in greater or less intensity, to the whole of the globe. In those cases, again, in which the posterior part of the retina is attacked, these vessels are, from their situation, exempt from the excitement, and the disease thus remains insulated, unless it should gradually extend to the anterior margin, when they become involved, and the barrier is at once overcome. This seems to be the explanation of what is observed in certain cases of internal ophthalmia. There is rapid extinction of vision, intense pain, photophobia, and photopsia, but no external appearances commensurate with the severity of the symptoms; this continues for a longer or shorter period, during which we may suppose that the inflammation, having commenced at the deepest part of the retina is gradually travelling forwards; and accordingly, the period at which it attains the anterior limits is marked by the almost simultaneous implication of the whole of the contents of the globe.

The diagnosis of acute retinitis is sufficiently simple, the symptoms being so strongly marked that they cannot be mistaken; but it is impossible, at the commencement of the attack, to predict whether or not the inflammation will extend to the other membranes. This information, could it be gained, might modify the prognosis, as the complicated form seems to be much more intractable and fatal to vision than the simple; fortunately, it is of no importance as regards the treatment, which ought to be the same in both forms of the disease.

From the extreme intolerance of light and tenderness of the eyeball, it is impossible to make a minute examination without employing considerable force, and subjecting the eye to much rough handling; this is attended by great pain to the patient, and probably, also, by serious injury to the retina from the sudden access of the light; therefore, as the information it would convey is of no practical value, it would appear to be better practice to rest content with the occasional glimpse that may be obtained by the voluntary efforts of the patient in a darkened room. It is true, that the pain and spasm might be overcome by the employment of chloroform, but it is questionable whether the retina might not suffer an equal amount of injury from exposure to the light, though the patient might be in a state of unconsciousness.

It will be observed, that, in the treatment of this case, notwithstanding the severity of the symptoms, neither general nor local bloodletting was employed; that reliance was placed exclusively upon mercury, and that recourse was had to tonics at a very early period. The same general plan was adopted by Mr. Cooper, and with equally fortunate results.

This is not in accordance with the views of the great majority of authors upon this subject. Free local and general bleeding, even "coup sur coup," after the manner of M. Bouillaud, and general antiphlogistic measures, of the most energetic character, are almost universally enjoined. Mr. Tyrell and Dr. Jacob are almost the only British writers on ophthalmic disease who have pointed out in strong terms the injurious consequences of copious depletion, and the advantages to be derived from an opposite plan of treatment, especially among the class of hospital patients. I believe I am correct in stating, that these views have now been adopted by the great majority of those who have an opportunity of seeing much of the diseases of the poor in large cities; and that the sanguinary measures which may have been required by a more robust generation have been now completely abandoned.

M. Desmarres strongly recommends in these cases the repeated evacuation of the aqueous humour; but, as he does not speak from experience, the propriety of this plan may be questioned.

82, Guildford-street, Russell-square.

CONTRIBUTIONS TO DENTAL SURGERY.

By C. SPENCE BATE, Esq.

ON IRREGULAR TEETH.

Perhaps, in order to derive the greatest advantage, in a practical point of view, there are few departments of dental science which more require the combined research of a large number of the Profession than that which is the subject of this paper.

The knowledge which we have of the history of the teeth, and the lesions to which they are liable, teaches us that much of their beauty, health, and permanent durability depends upon the position which they respectively hold in relation to one another in the jaw, and that much of the grace in the expression of the human countenance is the result of a set of well-developed teeth, forming a perfectly normal arch. Then valuable indeed must those researches prove which assist towards an approximation of overcoming the difficulties which interfere with such result.

That much yet the most skilful have to learn, I think the following history of an anonymous case will show,—anonymous both as to patient and parties consulted, for it is not pleasant to mention names unless we can do so with praise. It alludes to a young lady of very prepossessing appearance, except for a most unsightly disarrangement in the placement of the teeth.

Unfortunately, she is the member of a family, though amiable and pleasant in all the duties relating to social intercourse, yet incapable of placing confidence beyond the limits of their own small conception, and to this, I believe, is due much of the result which still leaves a shade upon the value of the opinion of more than one who had been consulted.

The jaw was always cramped and narrow, and the teeth large and well developed, and was precisely one of those cases wherein much attention was necessary; the permanent teeth cut the gums in every instance without absorbing the fangs of the deciduous set; and, if my memory is not peculiarly treacherous, nearly all the deciduous teeth were removed in order to permit the others, already grown, to fall into their more regular position. The laterals, as may be seen from the adjoining figure, (*Fig.* 1), made their appearance behind

Fig. 1.

the normal arch; the result was, that the deciduous lateral incisors were removed, and not at all improbable that the deciduous canines were also taken out. The bicuspids next came into sight, holding their natural position, but approximating so near the lateral incisors that the canines could possibly have no room to permit them to occupy a position in line with the rest, and therefore were driven through the gums external to the arch, tusk-like and unpleasing. This position of the canines must have been the great impediment which precluded the laterals from being forced by the natural pressure of the tongue into regular line with the two central incisors.

It is not my intention to discuss how far it might have been within the reach of other treatment to have precluded such a relative position of the teeth; but, since such was the case, faithfully to record the history of the treatment pursued, and the result attained.

The teeth were in the position as shown in the cut when she was about 12 years of age, with the exception that the two first bicuspids were not removed when the child was

brought to me, after a long absence, for my opinion, which was, without hesitation, "the removal of the first bicuspids, together with the adaptation of mechanical means," which should be so employed as to force the lateral incisors forward, and at the same time bring the canines back.

The sound of a plate was intolerable, and the idea shook the confidence of my hearers as to the value of my opinion.

At their request, I took an impression of the child's mouth, and the model was sent to town, and a "most decided opinion" obtained, that, upon the removal of the first bicuspids, nature had sufficient power to restore the deformity to its normal regularity, even though, as was the case, the anterior face of the lateral incisors struck posteriorly to the opposing teeth in the under jaw.

A year passed away, and I again saw the child; when I was told by her friends, that I might do what I liked, except put a plate into the mouth. But I saw no reason to change my opinion, which had been strengthened by that of a dentist whom I had consulted, and in whose judgment I have great confidence; and, besides, I would not accept a case trammelled by similar conditions; and so a second year was allowed to pass, with only the additional assistance of a long stick or pole (recommended by the party previously consulted) to be used to push back the canines.

Time told its tale; the stick failed in its work; and a doubt sprang up as to the correctness of the opinion given.

Another was consulted, and pronounced (so said the child's father) the capability to restore the teeth to regularity not to exist, the child now being 14 years of age. This or a similar opinion was given by one or two others of equally high repute; and the result was, that the lateral incisors were removed, and now the mouth exists with four teeth in the front, to occupy the place where eight usually stand. I see her often, but always with regret and reproach; regret, that a face otherwise so pleasing should be in this way spoiled; reproach, that we are still so far behind that we should not have known there was but one right way, and that our judgment had failed because it had not been unanimous.

My own connexion with this affair is such, that none but the most illiberal will see aught but honesty of purpose by the detail. That I wish to press strongly on the minds of the Profession, that much is yet done, even under the direction of the most experienced practitioners, (for they all stand high, none higher, in reputation, and justly so too, who were consulted,) which cannot, judging by the result, be pronounced either skilful or correct. Then would it not be wise, nay, is it not a duty which each owes his neighbour, that all should combine, that each should dot down his own experience, and so enlarge his sphere of doing good.

I have seen a child take up a stone and fail to hit the mark at which it aimed; I have seen it followed by another from a man's nervous arm, while emulation still made others repeat the act, until the mark was struck, and so success resulted from the young child's first endeavour.

If this small cast of mine be just as fortunate, it will afford a little pleasure to remember.

It is not my intention to speak of any cases of ordinary regulation, such as those which occur when children shed their teeth, and is corrected by the removal of those teeth which, in the ordinary course of nature, should have been previously dislodged by a more speedy absorption of their fangs.

I believe the opinion is fast gaining ground, that much more injury of a permanent character is done by the too early than the too late removal of the deciduous teeth.

It should be remembered, that bones only grow at the extremities, and that the simphysis of the lower jaw has become obliterated by ossification, and the right and left bones unite to form one; thus no growth can take place except at the posterior extremities of the jaw.

But nature has ordained, that the space occupied by ten deciduous teeth shall, upon their being removed, be replaced by the same number of a more permanent character; but although this may be the case as regards the whole, it is not correct in relation to each separate tooth, some of which are larger, while others occupy less room; and the object of the dentist is so to economise the space that the new ones may be enabled to take possession of the whole; for this purpose, with discretion, it may be said, we can scarcely keep the deciduous teeth in too long, for the fangs, by their position, act as wedges between the new developed teeth, and preclude a too great tendency of compression from the lateral pressure of the posterior teeth.

This, which appears to me to be a sound reason for precluding too early an interference with the incisor teeth, becomes increasingly so in relation to those teeth which are later in their progress through the gums, insomuch that the evil is extended over a larger space in the jaw, and a greater extent in relation to time.

Independent of the advantage which the presence of the fangs may have in a mechanical point of view, as above stated, it can scarcely be expected that the deciduous tooth can be forcibly removed from its position, which is in immediate contact with soft vascular tissues connected with the new organ, without a liability to interfere with its healthy action, even in single teeth; whereas, in the double teeth, any irregularity or distortion of the fangs may so hug the new incomplete organ, as to bring away the permanent tooth in its grasp. *Fig.* 2.

It is such a case I figure here, which could not have occurred had time been granted, so that the natural absorption of the fangs had not been interfered with.

In this case, the tooth was not, I believe, removed with a view to accelerate the regular position of the teeth, but was demanded in consequence of great suffering on the part of the child; and the practitioner who sent me the specimen is by far too careful an operator, and stands too high in reputation, to suppose that less than the greatest caution and skill had been exercised. But still I contend, that the result proves, that the tooth was removed earlier than was conducive to the normal character of the permanent set. Although, happily, such accidents are not of frequent occurrence, yet the possibility shows the liability; and when this has once been demonstrated, he who risks the chance must undergo the charge of rashness.

But it must sometimes occur that caries has so early progressed, that the pulp of the deciduous teeth may become liable to the influences of external agencies. It is a great comfort to remember, that odontalgia in children is generally of so mild a character, that fomentation of hot water and a mild aperient will seldom fail speedily to remove it, and that it is of the highest importance that they should be preserved as soon as relieved, by being filled; but, in case of failure, or the tooth being in a state too carious to bear the force necessarily required for such an operation, I believe the most proper and scientific mode of proceeding is to excise the crown, and leave the fangs behind; these act the part, as I have before observed, of wedges, and prevent the posterior teeth from dropping into the alveoli, rendered vacant by their removal.

It may be brought in argument, against the plan of excision, that it has been found, as in cases of pivotting a new crown on the fang of a permanent incisor, that much pain and suffering may follow the operation. It may be also said, that when a tooth has been broken in the operation of extraction. Great inflammation and worse pain often follow than existed before the operation was attempted.

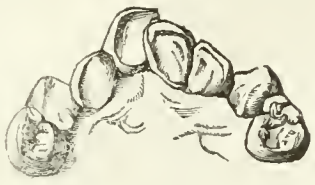
These are cases of failure, and not the evidence by which a successful operation should be tested. If excision of the deciduous teeth, such as under certain circumstances I recommend, be performed upon a similar plan, the result will be the same; but, if the operation be performed so as to remove the crown with a clean division, so as to bisect the nerve pulp nearer to the roots of the tooth than its bulb, so as to carry the latter clean away with the chamber in which it exists, at the same time no splinter of the tooth be allowed to remain,—if this be done, and the operation performed with a steady hand, so that no dislocation be given to the fangs in their connexion with the walls of their alveoli, experience has taught me through the last twelve years, that no disagreeable result will follow as a consequent of the operation in deciduous or permanent teeth.

Still there are cases where even this cannot be recommended; for instance, where the teeth are loose, or the source of irritation to the surrounding tissues. The surgeon must judge of the influence which local irritation may have upon the general system, and not forget that much of the future health of the teeth depends upon that of the whole body.

The power which the posterior permanent teeth, during their development, exercise upon those which are situated anteriorly to them in the jaws is shown to commence at an

early date, by the history of the following case, represented by the subjoined cut.

Fig. 3.



It is that of a child about five years of age, in whom, as its mother tells me, the teeth were originally developed in their regular or normal position; but about twelvemonths since she observed the central incisor to be pressed forwards, which continued to increase until it became as at present figured. The permanent molars will not cut the gum, most likely for a couple of years, and it is not improbable that the irregularity may still increase; the projecting incisor is loose, and will certainly be displaced before its permanent successor has sufficiently progressed to supply its place. What may be the future history of the case we cannot tell; but a serious disarrangement of the second set will most probably be the result.

The whole of this compression of the teeth I think must be attributed to a want of corresponding growth in the jaws to admit of the presence of the permanent teeth, the molars of which press so strongly against the anterior teeth that they are driven out of their position.

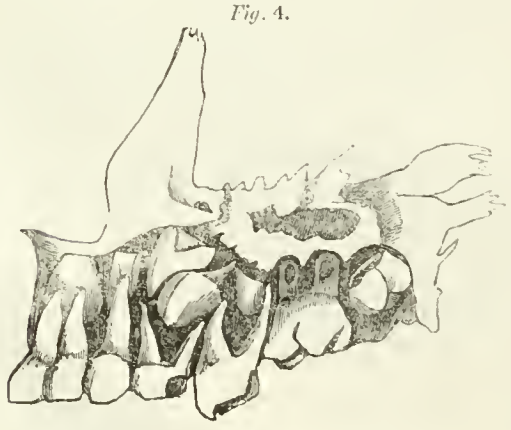
The child is healthy, but of a very peculiar countenance, probably arising from the great projection of the brows over the eyes.

After the first molars, the teeth of both the upper and the lower jaws which make their appearance through the gums are the central incisors, and these are followed so quickly by the laterals, that should they (the centrals) be at all irregular in their position, the short time which the deciduous laterals would retain their place can have no comparative influence upon the whole, equal to the advantage gained to these teeth by the regularity obtained through their removal; but the probability is, that in consequence of such a proceedure being necessary, the lateral will be jammed between them and the canines, and driven out of the line of regularity in the dental arch; this the more readily, since the normal position of the tooth when in progress of development within the jaw is diagonal on its own axis, as compared to that which it will assume when permanently developed.

Where such is the case, the usual practice, almost I believe universally adopted, is the removal of the adjoining tooth, viz., the deciduous canine, which produces the desired effect, and the irregular lateral drops into line with the teeth already developed.

The next in order which nature produces are the bicuspids, the permanent canine being deeply imbedded in the jaw. (*Fig.* 1.) These have a tendency to press forwards, owing to

Fig. 4.



the pressure of the teeth which are in progress of development at the rear of the jaw; unfortunately, the removal of the deciduous canine at a period long anterior to that when its permanent representative can occupy its place, by rendering vacant so large a chasm as its own alveolus becomes, must tend to accelerate this evil; and it results as a natural sequence that the permanent bicuspids and the lateral incisors will closely approximate each other; later in the history of the teeth (about two years after the incisor) the canine will be found pressing to come through; but finding its natural position pre-occupied, by force of its own growth, it is driven within or without the arch, which latter is the most common form of irregularity which this tooth assumes.

Not only the position which the bicuspid and incisor teeth hold in relation to each other, induces this displacement of the canine, but tends greatly to retard it from completing its full development; and thus it is not unfrequently the case, that the canine shall not progress beyond a mere protrusion through the gum, existing a tooth in name, but useless as an organ, or, in the most favourable of cases, can only be restored to the line of beauty and usefulness by the loss of some other permanent tooth. In order to preclude such consequences, it becomes a scientific dentist to adopt those means which shall best preserve intact the space allotted to the new teeth, upon the removal of their former representatives. This has, no doubt, occupied the attention of many; and Mr. Bridgeman, of Norwich, has suggested the application of mechanical means, ("Forceps," Vol. II., p. 58,) in order to keep open the space left by the removal of the deciduous canine; but this must naturally be ineffective in its result, inasmuch that the pressure required to fulfil such a purpose must either preclude the lateral from assuming its normal position, or it must encroach upon the space left, to admit of which encroachment the canine tooth had been previously removed. M. Toulon, in a memoir read at a Session of the Royal Academy of Medicine, Paris, suggested the application of pressure to the whole series of teeth, so as to enlarge the arch of the teeth and the dimensions of the palate, until it was of sufficient range as to grasp all the teeth in an even line. (Forceps, Vol. I., p. 69.)

The plan which I adopt, and which, although it originated independently, and had been carried out in my practice previously, with cautious timidity, being then a young practitioner, still it would be unjust not to acknowledge the confidence I received from a short paper in the "Forceps," Vol. II., on the same subject, published by Mr. Lintot, wherein he states, having pursued an important portion of the treatment which I propose, although the remainder, to which he has not applied, I contend to be equally essential to the successful issue of the case.

Nature should be followed, and it is the discovery and close approximation to her plans that is the path of science.

The succeeding tooth which is shed to that of the incisors is not the next in position, but the two molars, which are posterior to it in the jaw. If nature plans it so, is science to contest the law, and try to rule it different? He who does, may regulate the incisors, but he will render distorted the relative position of the others.

We can scarcely do better than follow the order of succession; and when the lateral incisors of either jaw be compressed, or distorted from their natural position, the right tooth to remove is one of the deciduous molars, the most useless, either from caries or other causes, reserving in preference the posterior.

This, so far, agrees with Mr. Lintot—nature being left to fulfil the rest. But my own experience teaches me, that they who expect a happy result to follow with no other artificial interference, will risk disappointment; for the posterior teeth are more apt to be pressed forward from the growth of the permanent molars than the canines to yield their position to the lateral pressure of the growing incisors.

Believing this to be the case, it is my usual rule to slip a ring, made of vulcanized India-rubber, over the canines, and, if possible, over the second deciduous molar; thus assisting the pressure of the growing incisor to push the canines away, which, upon being sufficiently removed, the band should be transferred from the canine to the incisor, taking care that it should pass the canine, so as to make it serve as a pulley on that side which shall force the irregular tooth into its normal position. Caution should be taken whenever an India-rubber ring is used that it be not too strong, since the pain and inflammation which would

thereby ensue is liable to prove of great inconvenience as well as suffering.

I have found this a simple, easy, and safe mode of treatment; the bicuspids now develope themselves in their natural position, while the deciduous canines reserve a place between them and the incisors for development of the future permanent canines. Thus regularity of position is obtained by a far more certain and less painful process than the one usually adopted.

[To be continued.]

THE LONDON PRACTICE OF MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

By HARVEY LUDLOW, Esq., M.R.C.S.E.,
Late House Surgeon.

ON INJURIES OF THE ARTERIAL SYSTEM.

The following cases have occurred in the practice of the hospital during the last three years, and may, perhaps, be considered not unworthy of attention, as they illustrate points in surgery neither surpassed by any in importance or inferior to any in interest.

COMPOUND COMMINUTED FRACTURE OF THE LEFT SUPERIOR MAXILLARY AND MALAR BONES, FOLLOWED BY PROFUSE ARTERIAL HÆMORRHAGE FROM THE PTERYGO-MAXILLARY FOSSA.

Case 1.—Harry Dicketts, aged 34, was admitted May 28th, 1850, at 5 p.m., under Mr. Stanley, with severe contusion of the whole left side of the face, and an irregular wound over the zygoma, attended with laceration of the deep tissues, and with fracture of the malar and superior maxillary bones. The injury was occasioned by a blow from the iron handle of a powerful crane, whirling round with terrific force under the traction of a heavy carriage, whose weight had overpowered the arms of himself and a companion engaged in lowering it. He was knocked down, and blood issued so freely from the wound in his face, that he soon felt faint. No time was lost in bringing him to the hospital; but, on his admission there, the bleeding had ceased, and a deep wound, or rather a complete smash of the upper and posterior part of the left cheek, comprising the posterior portion of the malar bone, zygomatic process of the temporal, and tuberosity of the superior maxillary, was all that appeared. The contusion attendant on so violent a blow had produced great swelling of the face, and such ecchymosis of the lids, that the eye could not be opened.

His occupation was that of a coach-painter; his habits were temperate, and constitution vigorous.

Shortly after admission he was put into a warm bath, in accordance with the rules of the hospital; (a) but, he had scarcely entered it, when the wound began to bleed with great freedom, and continued to do so for five hours, notwithstanding incessant attention.

Removal of the clots, and exposure of the bleeding surface to the air, the application of ice, and compression of the common carotid in the neck, (a proceeding which caused great pain,) were all ineffectually tried. At length, however, the house-surgeon, Mr. Archer, succeeded in arresting the hæmorrhage by plugging the wound with pads of lint, steeped in the tinct. ferri sesquichlor. The patient lost a large quantity of blood, his shirt and bed-linen were quite saturated, and his pallid face and feeble pulse told how great had been the drain on his system.

29th.—No bleeding occurred in the night; his pulse was very feeble; countenance pale and covered on the left side with black masses of dried blood. There was great swelling of the face, and both eyes were closed from swelling, and ecchymosis of their lids. He complained of feeling very weak.

Ordered milk diet, with two pints of beef-tea daily.

About the middle of the day there was slight recurrence of the hæmorrhage, and, as it had not ceased at 5 p.m., Mr. Stanley directed the plugs of lint to be removed, and the wound to be exposed. When this had been done, the impossibility of securing the bleeding vessel by ligature, or torsion, was apparent, for the blood welled up from the bottom of a deep pit, in which no object was distinct. The wound was filled with crumbled leaves of matico, over which pads of dry lint were placed, and tightly secured by strapping. By this method the hæmorrhage was controlled.

As the act of mastication necessarily interfered with the tranquillity of structures adjacent to, and involved in, the injury, he was not permitted for two days to take any food by the mouth, being nourished by injections of strong beef-tea.

Fortunately there was no return of the bleeding. In three days the wound began to suppurate, and discharge escaped from beneath the dressings. These, however, were not touched till June 1, when the exterior pad of lint was removed and a bread poultice applied over the left side of the face. The remainder of the lint and the matico were gradually discharged, and, on June 3, the wound was seen to be clothed with granulations, and secreting a quantity of strong-smelling pus.

The wound filled up, and the swelling of the face subsided. Three days after admission an attack of inflammation came on in the right forearm, around a slight wound which was inflicted simultaneously with the injury to the face; this, however, readily yielded to leeching and poultices. During the first week of his sojourn in the hospital, some difficulty occurred in overcoming the constipation of the bowels, and it was found necessary to relieve them by injections of gruel. A nutritious, unstimulating diet was allowed him, and though his debility was such, that on rising from the bed four days after the accident, he fell back and fainted, yet he made rapid progress to recovery, as the following note, taken on the 18th of June, will testify:—

"His condition is in every way satisfactory. The wound has nearly filled up, and is much contracted in superficial extent. He can move his lower jaw pretty well, and without much pain."

He left the hospital at the end of June, quite restored to health.

In the above case, the operation of securing the bleeding vessel at the point of injury would have been impracticable, and had the hæmorrhage continued, Mr. Stanley was resolved to tie the common carotid artery, believing that the patient would receive more complete security from such a proceeding than if deligation of the external carotid were practised. The case also affords an example of the constipation following large losses of blood, alluded to by Mr. Skey in his Work on "Operative Surgery."

SMALL PENETRATING WOUND OF THE FOREARM PIERCING THE ULNAR ARTERY, AND CAUSING EFFUSION OF BLOOD.

Case 2.—Thomas James, aged 15, was taken into St. Bartholomew's Hospital, November 16, 1850, on account of a diffused swelling of considerable size, which existed along the inner side of the right forearm, and was placed over the upper two-thirds of the ulnar artery. The tumour was felt to fluctuate obscurely, and slight ecchymosis was manifested in the skin that covered it. The cicatrix of a small wound was visible about midway between the bend of the elbow and the wrist, corresponding almost exactly to the middle of the ulnar artery. Not the slightest pulsation was perceptible in the tumour, nor was any bruit audible on the morning of his admission, although, in the afternoon, after the arm had been freely handled, many gentlemen heard one distinctly.

The boy was a doll maker, and, a fortnight before his admission, while engaged in his work, he wounded his arm at the spot indicated by the cicatrix with a long narrow knife, which pierced, according to his statement, to the bone. Very little bleeding ensued. A week elapsed from the injury before the arm began to swell, and then a gradual enlargement took place, which went on increasing for four days, since which time he considered it had been slowly diminishing, and, at the period of his admission, he believed that it was subsiding.

By this history the case was rendered very obscure; a consultation was held respecting it, and several examinations of the arm were made. Both radial arteries were found beating with equal force, but the pulsation of the ulnar in the affected arm, though evident, was much enfeebled. Shortly after his admission, the boy was seen by Mr. Hodgson, and that gentleman came to the conclusion, that the main artery had not been wounded, for the following reasons:—1st. Because the hæmorrhage following the infliction of the wound had been so trivial. 2ndly. Because the tumour did not pulsate. 3rdly. Because the swelling did not begin till some days subsequent to the injury, and latterly had rather diminished than increased. Mr. Hodgson felt disposed to think it was an abscess. Both Mr. Stanley and Mr. Skey expressed themselves as quite uncertain respecting its nature. Mr. Lloyd was inclined to believe the ulnar artery had been punctured, but, considering the doubtful nature of the case, he determined to wait till the following day before adopting any decisive treatment respecting it.

In the evening, no increase of the swelling had taken place, but an aneurismal bruit was distinctly audible, so that it now seemed pretty clear that the artery had been wounded. Still there was not the least pulsation of the tumour.

On the following morning, the bruit was again clearly heard; the lad was, therefore, brought into the theatre, in order that the wounded vessel might be secured.

(a) Every patient, on admission, has a bath, unless his medical attendant forbids it.

Mr. Lloyd made an incision into the tumour, three inches long, over the course of the upper third of the ulnar artery. A large quantity of coagulated blood was exposed, and cleared out from beneath the integument and between the muscles; after which the artery was found at the bottom of the wound, and seen to present anteriorly a small aperture, at a point corresponding in situation to that of the cicatrix in the skin, secured above and below the puncture. The vessel was in its wall. The wound was brought together by sutures, and water-dressing applied to the arm.

The next day, faint pulsation could be felt in the ulnar artery below the ligature. Numbness in the fingers, supplied by the ulnar nerve, existed for two or three days. Both ligatures came away eight days after the operation. The wound healed by granulation, and the lad left the hospital December 19th.

PENETRATING WOUND OF THE FOREARM—PUNCTURE OF THE ULNAR ARTERY.

Case 3.—William M'Kenzie, aged 28, was admitted January 20th, 1852, under the care of Mr. Paget.

The left forearm was much enlarged anteriorly, and an oblique wound existed on the ulnar side, corresponding to the upper ulnar border of the pronator quadratus. A dirty grumous clot protruded through the skin, pulsation was evident in the swelling, and a bruit could be heard with the stethoscope. The man was pale and weak from repeated losses of blood.

Three weeks before admission he wounded his arm, while cutting a piece of holly. A jet of blood followed the knife, and the arm began to swell rapidly. He bound his handkerchief tight round the wound, and so prevented the loss of more than a teacupful of blood. Afterwards he applied to a surgeon, who directed him to bathe the arm in warm water and use poultices. All went on well for a week, but at the expiration of that time bleeding from the wound occurred, and he lost half a pint of blood before the hæmorrhage could be controlled. The arm, which had almost regained its natural size, again became largely swollen. On the arrival of a surgeon, a compress and bandage was applied. Subsequent to this date, however, hæmorrhage occurred repeatedly; for whenever the bandages became slack, owing to the diminution of the swelling in the arm, blood issued freely. During the third week after the accident he lost in the middle of one night more than two pints of blood.

Having squeezed out a quantity of grumous clot, Mr. Paget made an incision upwards from the wound, along the course of the ulnar artery, about four inches in length. The loose coagula which everywhere pervaded the inter-muscular spaces and muscular tissue rendered it extremely difficult to discover the vessel. It was found at length, pushed quite out of its course by the clotted blood in its vicinity, and itself plugged by a coagulum for some distance upward, so that no pulsation was perceptible in it. Mr. Wormald, however, having succeeded in finding the aperture in its wall, passed a probe into the interior of the vessel, and displaced the clot. Arterial blood freely followed. Double deligation of the artery was then practised.

For some days after the operation, the man complained of coldness and loss of sensation in the ring and little fingers, extending thence to the wrist. Indeed, more than three weeks elapsed before the natural sensibility returned. The wound threw up granulations, and quickly healed, and, though the movements of the fingers were for some time greatly interfered with, the patient gradually regained their free use, and left the hospital, Feb. 22, quite well.

PUNCTURED WOUND OF THE RIGHT FOREARM, FOLLOWED, AFTER THE LAPSE OF A WEEK, BY PROFUSE ARTERIAL HÆMORRHAGE. — DELIGATION OF THE ANTERIOR INTEROSSEOUS ARTERY.

Case 4.—William Griffiths, aged 23, was admitted April 26th, 1852, under the care of Mr. Lloyd, having an oblique wound in the right forearm, corresponding in situation to the middle third of the ulnar artery. The injury had been inflicted four hours previously by a chisel an inch broad. There was no bleeding from the wound at the time of his admission; he was therefore sent to bed; the limb was kept in an elevated position, and water-dressing applied.

History.—A carpenter by trade happened to be carrying a chisel in the outside pocket of his shooting-coat, and, while in the act of jumping from a cart, drove it deeply into his arm. A stream of red blood spurted from the wound. Being at the time four miles from London, he bound up his arm tightly with a handkerchief, and went to a surgeon, who applied strapping and bandage. On arriving at his home, the wound bled again through the bandages, and he was therefore advised to seek relief at the hospital.

Eight days after his admission, profuse and alarming hæmorrhage occurred, which was commanded by the application of a tourniquet to the brachial artery, and a bandage to the forearm. The following day the tourniquet was removed, but no blood issued from the wound; the forearm was swollen and tense, and the man looked very pale, and was much enfeebled.

Bleeding took place on the 7th and 8th of May, though not to a large extent. The wound in the forearm now presented a sloughy aspect, and its edges were separated by a grumous, dirty-looking coagulum.

On the 8th of May he was brought into the theatre, and an incision made along the course of the ulnar artery, extending upwards from the wound. The clots were sponged away from the infiltrated muscles, and search made for the wounded vessel. Blood continued to rise from a point deep in the middle of the forearm, when pressure was withdrawn from the brachial artery. In this direction, therefore, the dissection was pursued. The median nerve, which appeared to have been wounded, was drawn to the radial side, and, at a little distance beneath it, the bleeding vessel was exposed, having a slit in its anterior wall, through which a probe was easily passed. Ligatures were applied above and below the wound. The depth at which the vessel was placed from the surface, and its situation in the middle of the forearm, proved it to be the anterior interosseous artery beyond a doubt. Water dressing was applied to the wound, and the man sent back to his bed.

There has been no recurrence of bleeding since the operation. Both ligatures came away in a week. The wound soon began to discharge and granulate actively. Neither before nor since the operation has it been possible to feel any pulsation of the ulnar artery in the injured arm.

The patient is still in the hospital, and has nearly regained the use of his fingers, whose movements suffered considerable impairment in consequence of the injury. The wound is contracting day by day, and its cicatrization advances with rapidity.

These three cases admirably exemplify the important fact, that wounds of the arterial system are not always immediately followed by profuse hæmorrhage,—such hæmorrhage as would indicate at once and conclusively the full extent of the injury. This circumstance is insisted on by Mr. Guthrie, and ably illustrated by numerous cases reported in his valuable work. The lesion of a large trunk, such as the femoral, is, indeed, almost invariably followed by immediate and abundant bleeding—bleeding which declares unmistakeably the nature of the injury, and which, unless promptly controlled, is soon fatal. The slight muscularity possessed by the walls of large arteries, and the force of the blood-current moving within them, fully account for the alarming hæmorrhage which occurs instant on their lesion. Devoid, or almost devoid, of contractility, and distended by a current of blood strong with the last impulse of the heart, they are able to offer no effectual resistance to hæmorrhage, or even to lessen the effusion of blood by contractile diminution of their tubes. But arteries of inferior size, in whose coats there is less of the elastic and more of the muscular tissue, are able, by virtue of the latter structure, to diminish their calibre, or even for a while to close themselves completely, under the circumstances of injury. Thus the flow of blood is lessened, and perhaps wholly checked; but general excitement of the system, either from the injury itself, or from some other cause, sooner or later supervenes, the circulation is carried on with stimulated vigour, while the muscular coat of the wounded vessel, fatigued by long action, becomes now altogether unable to withstand the increased impetus of the blood, relaxes its opposition, and hæmorrhage is the result. Now, if it were possible, by artificial means, to check or lessen, for a time, the stream of blood through a wounded artery, an opportunity for reparation would be afforded it, such reparation as, if completed, might restore the part to a condition of nearly perfect integrity, and render a long, tedious, and difficult operation unnecessary. In injuries to the radial or ulnar arteries, for example, a graduated compress applied to the brachial, and the pressure of a moderately tight bandage, from the fingers to the axilla, would, in all probability, succeed in establishing so desirable a termination; and, should they fail, the patient will be in no worse condition for the performance of an operation than before the attempt. Of course, it is not to be expected, that where a long slit has been made in an artery, spontaneous reparation will ensue; but the treatment by pressure is applicable especially to those cases in which the artery has suffered only a small puncture, or in which its penetration is suspected rather than known. I fully believe, that the timely and efficient application of compresses and bandages in cases of this description, would prevent the formation of false aneurism in many instances, and consequently the necessity of the operation adopted for its cure.

ST. GEORGE'S HOSPITAL.

By Dr. BARCLAY,
Medical Registrar.

SECONDARY DEPOSITS.

This denomination is perhaps objectionable as applied to the defined abscesses found in different parts of the body in fatal cases of suppurative fever, because it is apt to suggest the thought of syphilitic poison, of which the various events have been called, according to their acknowledged sequence, secondary and tertiary affections; and it might be advantageous to define this condition more precisely as secondary purulent deposits. The term in itself is a rational one, because it conveys a just idea, and serves to impress upon the mind the true nature of the disease; not that the whole abscess is nothing more than a deposition of pus from the blood, but that it owes its origin to this cause.

The true relations of this subject were first observed with reference to the consequences of operations, where it was shown, that on some occasions during the progress of suppuration the whole blood became tainted with pus, to which the name of "pyæmia" has been applied, and that the pus-globules were very apt to become impacted in the minute capillary vessels, and there become foci of inflammation and suppuration. That these are not the only circumstances in which such events occur, the subjoined cases must prove; although we have yet to learn the causes which determine, in these and similar instances, the presence of pus in the blood, while others apparently similarly situated escape.

Case 1.—The first case here detailed appears to have commenced as subacute rheumatism. Several similar instances have occurred while I have held the office of Registrar at this Hospital, in which the patients were admitted with inflammation attacking several joints at the same time, and therefore believed to be rheumatic, which has gone on to the formation of pus in and around the joints, and not unfrequently to the formation of secondary abscesses in various parts of the body. Most of these have presented acute symptoms; they have chiefly occurred in persons of dissipated habits, and have always been attended with great prostration, excessive perspiration and tremor of the limbs, and not unfrequently with delirium, which has borne a strong resemblance to delirium tremens. The present case was of much milder character, and there was no reason whatever for supposing that suppuration had occurred in the joint previous to the inflammation and suppuration of the testicle, and yet the section of that organ indicated just such abscesses as we find more commonly in other parts of the body when the presence of pus in the blood, and its detention in the course of the circulation is the known cause of the secondary suppuration, and precisely similar to those found in this case also in the larynx and in the lungs. The case derives great interest from the rarity of secondary deposits in these two situations, viz., the testicle and the larynx.

Michael H., aged 28, was admitted into St. George's Hospital, under the care of Dr. Bence Jones, on August 6th, 1851. He reported, that, after exposure to cold and wet, he had suffered from pains of a rheumatic character, which were chiefly confined to the left shoulder during a fortnight previous to his admission. He appeared to have been a man of rather intemperate habits, and generally not of strong health. When admitted, his pulse was rather quick, and the tongue furred; the shoulder was tender, and moved with difficulty; but there was externally no inflammation or swelling. In this state he continued during the first four or five days, no acute symptom manifesting itself, and the pain being confined to the left shoulder; his tongue, however, continued foul, and he had some degree of sickness. On the 12th, the surgeon was called to examine the right testicle, which was swollen and tender, when he was ordered calomel and opium every six hours, and he expressed himself on the 16th as feeling much relieved, especially as regarded the pain in the shoulder, but the testicle was still much swollen.

On the evening of the 18th he had a distinct rigor, after which he sweated profusely; the pills were left off, and a saline draught with excess of ammonia given, and wine allowed him. Next day some abscesses formed on various parts of his body, two of which on the leg, and one on the left arm, were opened on the 21st. On the following day he was much lower; difficulty of breathing, with a sort of stridulous hoarseness, evidently referrible to the larynx, supervened, but not to such an extent as to threaten suffocation. The breath-sound in the lungs was loud, harsh, and bronchial, especially on the right side. The tongue was dry, pulse rapid, and he began to be delirious at intervals. Pustules formed over different parts of his body on the following day: his prostration greatly increased, consciousness was obscured, his breathing oppressed and heaving, pulse frequent and feeble. He sank rapidly, and died on the evening of the 24th.

Post-Mortem Examination Forty-three Hours after Death.—The body was not emaciated. On the outer side of the right elbow there was a small superficial abscess; and several pustules on the neck, body, and lower extremities; one or two small abscesses on the leg were open.

Left Shoulder-joint.—The capsule was slightly thickened; the synovial membrane contained some slightly turbid fluid, with small flakes of lymph and slight mixture of pus. A small spot of pus was found distinct in the substance of the left pectoral muscle.

Larynx.—There was considerable ulceration of the larynx, immediately below the true vocal chords, extending chiefly backwards, and also upwards, so as to implicate the aryteno-epiglottidean folds; around this ulcerated surface, which did not penetrate beyond the sub-mucous cellular tissue, were several spots of pus imbedded in the sub-mucous tissue; one of these was on the posterior surface of the epiglottis.

Thorax.—On both sides the pleuræ were firmly adherent for the greater part of their extent. The right lung was much congested throughout; on the posterior surface of the upper lobe were found spots of lymph and pus immediately under the serous covering. In the left lung, one or two spots of a similar character were also seen, but this lung was much less congested than the other.

Abdomen.—The viscera all healthy.

Scrotum and Testis.—The right half of the scrotum was very œdematous and dark-coloured; the right testis was enlarged to double the size of the other. The tunica vaginalis was slightly distended with straw-coloured serum, and the opposed surfaces were adherent through masses of recent lymph. The testis was much congested and inflamed, and in its substance were deposited small masses and spots of pus.

Case 2.—In the second case, the secondary suppuration had commenced before the patient's admission; but, from the history of the case, it was evident that uterine phlebitis had been the primary cause of the absorption of pus; and the case is interesting, as showing how the ordinary white-swollen leg of childbed may pass into a much more formidable and fatal disease, when the whole blood becomes poisoned by the presence of pus-globules, and these become the foci of secondary suppurations throughout the body.

C. W., aged 22, married, was admitted on the 17th February, three weeks after her confinement. She had been suffering ever since from severe pain in the abdomen, with rigors and copious perspirations; the right leg had become painful a week after her labour, the right hand and arm a week before admission, and the left hand only three days ago. The lochial discharge had ceased. Her face was emaciated, and the expression rather anxious; pulse 160. There was a large slough on the dorsum of the right foot, and pain, increased by motion, was complained of in the knee and ankle of the same leg, which was swollen throughout. The left knee and ankle were also slightly swollen, and were very much more painful than the right. On the back of the right wrist there was an abscess, which was opened soon after her admission into the hospital, and contained a quantity of greenish pus and a large slough—a few days later a similar one was opened on the left arm. She had been occasionally delirious during her illness. She had been under treatment, and, in addition to internal remedies, she had had fomentations, sinapisms, and blisters, the last giving her most relief. An attempt had also been made to limit the inflammation in the leg by the application of caustic, but ineffectually. Opium was given her at bed time, and bark with acetate of ammonia three times a day; wine and nutritious diet.

The tongue became more dry, the face was yellowish, she complained of nausea and thirst, and her cough was urgent, in consequence of which the bark was omitted on the 19th, and saline draughts, with excess of ammonia, substituted. But the respiration became more hurried, the face flushed, the tongue dry, and there was occasional delirium. On the 22nd, diarrhœa set in, but was checked for the time by chalk mixture and opium; and on the 25th, another abscess, which had formed over the right shoulder, was opened. There seemed to be some disposition to rally, and a drachm of the compound tincture of bark, and three grains of ammonia, were given in camphor mixture three times a-day.

She went on rather favourably for a few days, when diarrhœa again set in very severely on the 1st March. The abscesses which had been opened showed no tendency to heal: the tendons on the back of the wrists and feet were exposed, the tongue became aphthous, and the dyspnœa urgent; the body was covered with cold perspiration, the face became sunken and anxious, and she died exhausted on the 4th March.

Post-mortem Examination Thirty-two Hours after Death. — *Articulations.*—The left knee was enlarged; it contained a large quantity of darkish purulent looking matter, and at the inner side was an opening which communicated with a long sinuous abscess reaching as far as the upper third of the thigh under the muscles. In both ankle joints was much purulent matter, without much sign of inflammation; the cartilages were much absorbed, and on the denuded bone were one or two small vascular patches. The left wrist was similarly affected; the right wrist and ankle were healthy.

Thorax.—The left pleural contained a small quantity of serum, and some shreds of recent lymph; the membrane was very vascular. The lung was pale and emphysematous anteriorly, but congested behind, and the lower lobe and part of the upper lobe were inflamed and consolidated. The divided terminations of the small bronchi poured forth purulent fluid, and, being surrounded by portions of yellowish consolidated lung, gave the appearance, at first sight, of minute purulent deposits. The right pleural cavity contained some soft yellowish lymph, with one or two adhesions. The lung was pale and emphysematous anteriorly, and, on section, was found full of frothy serum and crepitant throughout, except at the margin of the upper lobe, where it was somewhat consolidated, and presented a portion, to the extent of about a shilling piece from which much purulent matter exuded on pressure. At the upper part of this lung some of the bronchi presented the same appearance on section described as found in the lower part of the opposite lung. The heart was healthy.

Abdomen.—Several old adhesions existed in the peritoneal cavity. The broad ligament and the peritonæum in the pelvic cavity were much congested, and the ovaric veins enlarged and tortuous, the right one being surrounded by a quantity of purulent matter in the sub-peritonæal tissue at its lower part, and filled with coagulum. The ovary on this side and the Fallopian tube were closely matted together, and there was pus in the sub-peritonæal tissue around the ovary, which was itself healthy. The tube itself also contained purulent fluid. The left ovary and uterine appendages were only congested. The uterus was large; its walls were thinned, and contained pus in its structure in the vicinity of the right cornu. Its cavity was dilated, and the lining membrane intensely congested, and covered by a watery bloody fluid; its anterior portion was shreddy and vascular.

The intestines presented patches of vascularity in the ileum, and several ulcerations in the cœcum of various sizes, with great vascularity. The kidneys were very vascular, and some yellow deposit was found at the apex of one of the pyramids in each; it was firm and striated, and seemed to be deposited between the tubes. The spleen was very soft. The large veins contained much coagulated blood.

THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

NEWCASTLE-ON-TYNE INFIRMARY.

By G. A. HUTTON, Esq.

CASES OF ANEURISM TREATED BY PRESSURE.

Case 1.—J. B., aged 48, blacksmith, admitted October 30, 1850; a pale, sallow-looking man, a hard liver and drinker; has popliteal aneurism of the right extremity, which commenced six months ago as a small pulsating tumour. He did not pay much attention to it, until pain and numbness of the limb and increase of the swelling obliged him to lay up.

At present, the foot and leg, up to above the knee, are much swollen and cold; the knee is a good deal bent and fixed. The limb around the tumour measures in circumference 20½ inches. The opposite limb at the same part 12½ inches.

To be kept quiet, and a cold lotion applied to the part.

Nov. 3.—The screw tourniquet of Weiss applied to the femoral artery.

4th.—The leg is more swollen; there is some ecchymosis over the tumour, and at one side of the patella. The leg and foot are quite warm. He bears the pressure tolerably well. Two tourniquets are in use, which are slackened alternately, in order to avoid pain and excoriation.

The increased swelling and ecchymosis appear to have been caused by the pressure produced when making a cast in plaster of Paris of the tumour.

15th.—The ecchymosis is fading; he now bears the pressure much better.

The limb to be firmly bandaged from the toes, and the pressure continued as before.

20th.—Mr. Bellingham's instruments for applying pressure were substituted for those of Weiss.

29th.—The tumour is diminishing in size; the patella is more defined, and the ecchymosis nearly gone; general health improved.

Continue as before.

Dec. 13.—The bandages removed from the limb. The tumour continues in the same state as at last report; has no pain; bears the pressure well.

Continue as before, but the pressure to be relaxed a little.

Jan. 10, 1851.—Compression removed altogether; no pulsation can be detected in the tumour; the articular arteries are felt distinctly pulsating. The tumour is not much diminished in size, but it has a soft, elastic feel.

An elastic bandage to be applied to the limb.

24th.—Since last report, he has continued to improve; complains of no pain; gets up and walks about on crutches. The tumour remains in the same state.

Feb. 4.—He is very unwell; erysipelas commencing about the knee of the affected limb.

9th.—The limb is much swollen; the erysipelas now extends from the toes to above the knee. The tumour fluctuates distinctly.

12th.—The tumour burst to-day, and about 12 ounces of dark matter, resembling coffee grounds, were discharged, but there was no hæmorrhage.

23rd.—He feels much better; considerable discharge from the opening in the tumour. Several portions of firm coagula of blood have been evacuated; no hæmorrhage.

March 16.—Since last report he has considerably improved; scarcely any discharge now; sits up and walks about occasionally.

21st.—He is very unwell again this morning; erysipelas present from the toes to above the knee; breathing with difficulty. These symptoms increased, and he sank and died on the 22nd.

Remarks, etc.—Previous to the examination of the limb, the femoral artery was injected with plaster of Paris. On dissection, the femoral artery was found injected down to the sac; the sac itself was filled with injection, lacerated in several places, and the injection extravasated into the surrounding tissues. The posterior tibial was partially injected. This case presents us with an instance of popliteal aneurism cured by pressure, but the ultimate result was unfortunate, the patient sinking at length from repeated attacks of erysipelas prevalent at the time. The patient was not a very favourable subject for any mode of treatment; his constitution had been injured by hard living; the tumour itself had attained great size, and interfered with the circulation of the limb, which was greatly swollen and cold. The complete cessation of the pulsation, however, and the absence of hæmorrhage when the sac gave way during the first attack of erysipelas, show that a coagulum must have formed at the entrance of the artery into the sac, thus cutting off its cavity from the general circulation. The coagulum was not probably very firm, as the injection was found after death to have found its way into the sac by the main artery. No conclusions adverse to the pressure treatment can be drawn from this case; erysipelas, indeed, would have been even more likely to have attacked the limb had a wound been made and the artery tied. In the broken down constitution, too, of this patient, the risk of purulent infection, which we sometimes see follow the most insignificant wound, would have been very great. The *post-mortem* examination shows that, as Mr. Bellingham has already stated, the artery is not obliterated at the point where the compression is applied.

Case 2.—The following case, which I have taken from Mr. Heath's Case-book, occurred before I became dresser.

E. O., aged 41, labourer at the Glass Works; healthy man, of temperate habits; admitted August 4th, 1848, with pain of the left knee, and swelling of the leg from the middle of the thigh down to the toes. The leg is very œdematous, and colder than the other. There is a tumour extending from about the lower third of the femur to two inches below the popliteal space, with distinct pulsation and bellows murmur in it. The circumference of the limb around the tumour is 20 inches; the opposite limb, at the same part, 15¾ inches. It was observed only a fortnight ago, and was then a considerable size. He knows no cause for it. General health good.

9th.—Pressure applied to the femoral artery with Weiss's screw tourniquet.

15th.—The tumour feels softer; the pulsation is much diminished; the circumference 19¼ inches.

22nd.—The tumour, and the general swelling and œdema of the

leg diminishing. The temperature of both limbs is now about the same.

Sept. 1.—Can now get up and walk about a little. No pulsation can be detected in the tumour. Popliteal space much more defined. Pressure removed.

29th.—Greatly improved; has no pain; the swelling is much diminished; can walk well now.

Oct. 15.—The circumference of both the limbs the same; a little hardness remains in the popliteal space. Cured.

This man remained perfectly well in the autumn of 1850.

Remarks.—This case affords a striking contrast to the preceding one, and presents us with a very favourable specimen of the pressure treatment. The patient, seven years younger than the subject of the first case, was of sound constitution and temperate habits. The case was so far complete at the end of three weeks, that the pressure was then safely removed, and the patient might have left the hospital a month earlier than he did, had it not been thought right to detain him for a time, with the view of watching the diminution of the sac. The cure of the disease was here effected as rapidly, with as little pain, and certainly with less danger than if the operation of tying the artery had been performed.

LIST OF SCIENTIFIC MEETINGS FOR THE WEEK.

This Evening,	June 5.	Royal Institution. *Subject:*—Prof. Faraday, "On Points Connected with the Non-Metallic Elements." Three o'Clock.
Monday,	June 7.	Royal Institution. *Subject:*—J. Conolly, M.D., "On Insanity." Four o'Clock.
——	——	Chemical Society. Eight o'Clock.
——	——	Epidemiological Society. — *Subjects:* —1. C. Finch, M.D., "On the History of the Introduction of Vaccination into India." 2. H. J. Stewart, Esq., Assistant-Surgeon Bombay Army, "On Vaccination in the Bombay Presidency." Half-past Eight o'Clock.
Tuesday,	June 8.	Royal Institution. *Subject:* — E. Lankester, M.D., "On the Physiology of Plants." Three o'Clock.
——	——	Royal Medical and Chirurgical Society. Half-past Eight o'Clock.
Wednesday,	June 9.	Royal Institution. *Subject:*—J. Conolly, M.D., "On Insanity." Four o'Clock.
Thursday,	June 10.	Royal Institution. *Subject:* — R. Westmacott, Esq., R.A., "On the History and Practice of Sculpture." Three o'Clock.
Friday,	June 12.	Royal Institution. — *Subject:* — Professor Faraday, "On the Physical Character of the Lines of Magnetic Force." Half-past Eight o'Clock.

Medical Times & Gazette.

SATURDAY, JUNE 5.

THE BOARD OF HEALTH AND YELLOW FEVER.

We were among those who expected great results from the establishment of the Board of Health. The formation of the Board gave a public expression to views widely diffused, yet scarcely recognised by the nation at large; and it appeared likely to direct scattered, and therefore comparatively useless, efforts into one uniform and useful channel. That these expectations have not been realised is owing to deficiency in the machinery, and not to want of truth in the subject. The members of the Board of Health, after nearly four years of office, have not advanced Sanitary Reform one *iota;* but have, on the contrary, disconcerted ardent friends, created powerful enemies, and damped the enthusiasm of the public.

That these results are in part owing to the mental character of the men who work the Board of Health, we have little doubt; but they are, no doubt, in part, attributable to the original constitution of the Board. We have repeatedly contended, that such a Board should not only be entirely medical, but should include within itself, either as actors or advisers, the highest medical science of the time. We did not say this from any narrow professional feeling, but from a profound conviction of its truth. The course of events has verified our anticipations.

The last Report of the Board of Health cannot be accepted by the Profession. With many points of good about it, bearing evidence of much thought and labour, it is yet vitiated throughout by one grand error. It starts from a pre-arranged hypothesis; its conclusion forms its foundation; it is not an inquiry, but a thesis—not the calm summing up of a judge, but the one-sided pleading of a counsel. Resolutely determined to reject *in toto* the theory of contagion, and the possibility of importation, the Board *huddles* together all the evidence it can collect for its own view, and carefully leaves out of sight the witnesses who are waiting to be called, and who are to present the other aspect of the case.

Dr. M'William's re-statement of the case of the Eclair, and the fever introduced by her into Boa Vista, is, for the most part, a summary of the evidence contained in his well-known Report. The case may be said to be re-argued from its old premises, and the former conclusion is re-affirmed. Dr. M'William proves, that the Board of Health have omitted evidence when they pleased, and have misrepresented it when it did not tally with their case. The exposure damnifies altogether the character of their Report, and is the most serious blow the Board of Health have had to sustain.

With what name shall we characterise this disposition of the Board to overlook incontrovertible facts and to set aside inconvenient testimony? Is it dishonesty, or is it ignorance, or is it partisanship?

Clearly the latter. The Board of Health fancy that the progress of modern doctrine is to do away with the theory of contagion. They perceive the absurdities of the modern system of quarantine, founded upon obsolete notions and dogmas of the Middle Ages, and they desire to abolish it. Both opinions are equally erroneous. The progress of science will certainly define more clearly the notion of contagion, but it will not undermine it. The wants of society demand a modification of quarantine, but they do not necessitate its abolition. The great object of medical science in this direction, is to learn how most safely as well as most expeditiously intercourse between nations can be carried on. This object will never be accomplished by the assertion of crude views, the adherence to unstable doctrines, or the proposal of unsafe rules of intercourse. Medical science will expose the falsehood of the one, and the national common sense will detect the danger of the other.

To deny, with the case of the Eclair before them, that yellow fever is sometimes contagious, and that it can be imported, is

to commit an equal error with Dr. Whyte, who denied the contagion of plague; and to omit all precautions in yellow fever countries would be as suicidal an act, as the inoculation which proved fatal to that unfortunate individual. There may be some Medical men who would not agree in this opinion, and who, with Drs. Gilkrest and Burrell, will ride to death their hobby of non-contagion; but it is indeed unfortunate that the responsible advisers of the Government in matters of health should hold such opinions,—opinions which we must stigmatize as erroneous, and condemn as dangerous.

Turning from the general question to one feature of it, nothing has more dissatisfied us in the Report of the Board than the way in which the Board, and those who have communicated their opinions to them, speak of the labours of Dr. M'William.

For ourselves, we hold that Dr. M'William, by the care and impartiality with which he investigated the Boa Vista epidemic, has laid, for the first time, a sure foundation for a true judgment. No criticism, however one-sided or however subtle, can destroy the simple evidence he has recorded; and no injustice on the part of individuals can affect the reputation which an investigation so masterly and complete has earned for him. That he is able to support his own ground, his excellent papers in these columns sufficiently show. We can only hope, that he may be tempted to analyse the other portions of the "Report," and let us know at what value we are also to rate them.

DISTRIBUTION OF MEDICAL APPOINTMENTS IN THE EAST-INDIA COMPANY'S SERVICE.

Within the last few weeks three appointments have been made in the medical staff of the East India Company which have afforded us considerable gratification, as they show how strong the tendency is becoming towards a faithful and honest distribution of the patronage in the hands of that powerful Company. A fortnight since the Assistant-Surgeonship bestowed upon the Medical School of St. George's Hospital, by Sir Benjamin Brodie, was awarded to Mr. George Nayler, and about the same time similar appointments, given to the respective Schools of Guy's and King's College Hospitals, were awarded to Messrs. William Bateson and Francis Macnamara. In all these cases, a very rigorous examination was undergone by the respective candidates,—a more severe one, indeed, than they would perhaps have experienced at either the Hall or the College; and it cannot, therefore, be doubted, that those who succeeded in distancing their competitors are really able young men, thoroughly versed in their profession.

Whilst we congratulate those gentlemen who were successful in carrying off what we trust will prove a golden prize, and open up to them a career of usefulness in our great Eastern empire, we cannot help, at the same time, congratulating the Profession upon the system of competition for such appointments, as its manifest tendency is to send forth young men to our distant possessions of far higher qualifications than the old method of private favour or *furtive* purchase was likely to do. And it was really high time that such high qualifications were demanded of our young military surgeons; for it must be remembered, that the army is no longer what it was. The examination passed by ensigns is so stringent, that every officer must now possess a scientific education, and, in many cases, the Military Colleges turn out young soldiers whose attainments would entirely throw into the shade those of the old school of military surgeons. For the sake of our own laurels, therefore, we must insist upon the thorough education of those students who receive either naval or military appointments; unless we wish to see the medical officer the most ignorant man in the mess-room, the system of private appointments of under-educated young men must no longer obtain. For the sake of the comfort and honourable position of the medical man himself, so much might be urged; and, on the part of the soldiers under his care, it might be still further demanded, that only the highest medical labour should be employed. The soldier, unlike the civilian, has no right of appeal, if we may so term it, for what he might consider the improper treatment of his medical attendant; he must die as unflinchingly and as uncomplainingly under the pills of his medical man, as under the bullets of the enemy. The medical officer has, indeed, the power of life and death over a thousand men; the very existence of such an authority ought to force upon those who have the means of conferring it, the necessity of providing that it shall not be abused, by ignorance at least. What we have said with respect to students receiving the appointments of military Assistant-surgeons, applies with equal force to those destined to fill the like situations in the sister Service. If the Government neglect to treat her officers with that regard and respect due to gentlemen, the Medical Profession must not, on that account, neglect to fit themselves in every respect for a position in itself so honourable, and involving so much responsibility. We hear that the Duke of Northumberland, the First Lord of the Admiralty, has placed at the disposal of the Middlesex Hospital a great many of the Naval Assistant-Surgeonships in his gift; and we trust, that, in future, the private and promiscuous distribution of this kind of patronage will be entirely abandoned.

THE CANCER HOSPITAL.

We took occasion to advert, a short time since, to the recommendation of the Committee of the Common Council to grant Dr. Marsden's petition for a hundred guineas towards his Cancer Hospital. When the matter came on for discussion in the usual form, it was only the accident of but one Alderman being present that prevented the recommendation of the Committee from being agreed to; and we were informed that, at the next Court, the sum would be certainly voted. The next Court was held on Thursday, May 27, and the recommendation on that occasion, after some little discussion, was *negatived*. This was no more than we expected; we knew it was sufficient simply to explain that the Profession were totally opposed to any such grant, and that the establishment of the proposed Institution would act injuriously on the Medical Schools of the Metropolis, and the large hospitals at present in existence; such an explanation we knew would set the matter right, and stop, *in transitu*, what seemed a job. Dr. Marsden was surprised, no doubt, to find this time the Common Councilmen fully understood the question. It was distasteful enough to hear Mr. Elliot say, "He thought if a medical gentleman, who was already connected with a large establishment for the treatment of diseases, was possessed of a specific for the awful malady of cancer, it would not only be an act of humanity, but an act of policy in that practitioner to exercise his skill in that establishment, and to communicate the invaluable secret to all others. He did not believe that Dr. Marsden had a specific for the cure of cancer, or had greater power over cancer than the Corporation itself had."

Mr. Anderton again sent a shaft to the very heart of the

question when he said, that "it appeared to him that there was nothing to prevent the reception of cancer-patients in that hospital (the Royal Free), and that, while funds were actually wanted for the support of that Institution, it would be unwise to agree with the Committee in their Report. * * *He apprehended, that the encouragement of local and partial institutions would tend to the injury of science*, by checking the practice of those who were endeavouring to excel in the Profession." Dr. Clark, to whose amendment the Profession owe the refusal of the grant, and [to whom we return our sincere thanks for the able manner in which he fought the motion in the Council, said rightly, that, by supporting such an Institution, the Court "would offer the greatest possible insult to the Profession."

The unoccupied condition of the Royal Free Hospital, at the very moment when its founder is begging funds to establish another medical charity, has struck most people as extraordinary. By one of those unlucky accidents which do sometimes happen at unfortunate moments, only a few days since, the advertisements of the two institutions were to be found in the *Times*, one over the other. First came the Royal Free, with the simple statement, that the hospital was capable of holding 500 beds, whilst it had the means of maintaining only 135; the public were accordingly moved in piteous terms to contribute to the furnishing of the odd 365 beds. The very next appeal to the public was in favour of the building fund of the Free Cancer Hospital, which is to contain only 50 patients. Why, in the name of common sense, exclaims every one, does not Dr. Marsden turn the Free Cancer Hospital into a *ward* of the Royal Free Hospital, seeing that he has such ample room? What right has he to hold out a couple of hats to the public, when the money he has got is sufficient for all purposes? If the Royal Free is such a rickety progeny, would it not be much more honourable towards the charitable and advantageous to the Profession, to nourish and support it with the means in his power, rather than to cry for help to enable him to give life to a second, and, in all probability, a less sound child? We do not think that Dr. Marsden's mind is thoroughly closed to conviction, and we put this question to him in a friendly spirit; indeed, we know that he is amenable to reason, for he has condescended to profit by our advice respecting the advertisements of the Cancer Hospital, to be seen from day to day in the *Times*. Really, it is astonishing to see the rapidity with which our strictures acted as a remedy in this case. We can only liken it to that striking pictorial Advertisement, in which, in one department, a poor wretch is drawn suffering from excruciating agonies in the tooth, and, in the other, is all happiness and joy, dancing about, and crying, "Ah! Ah! Cured in a moment!" or to the instantaneous effect of the operation for strabismus; or to the miraculous results arising from the simple cutting of a tendon in club-foot. In the first Advertisement, the reader will perceive certain statements (*italicised*) which give a painful aspect to it, and which we took occasion to comment on in a late article, (May 15).

Here it is, as before treatment:—

"FREE CANCER HOSPITAL, 1, Cannon-row, Parliament-street, London.

President.—The Right Hon. the Earl of Airlie.
Treasurer.—John Parkinson, Esq., 66, Lincoln's-inn-Fields.
Bankers.—Messrs. Coutts and Co., Strand.

This Institution has now been in existence twelve months, during which period a larger number of patients suffering under this dreadful malady has been brought together than at any other period, clearly showing the necessity there is for an Institution exclusively devoted to the treatment of *this hitherto-considered incurable disease*. Although many deaths have occurred out of the 206 cases which, up to the present time, have been under treatment, it is highly gratifying to report, that a large number have been greatly alleviated, and *several incipient cases discharged completely cured*," etc.

As after treatment:—

"FREE CANCER HOSPITAL,
1, Cannon-row, Parliament-street, London.
President.—The Right Hon. the Earl of Airlie.
Patronesses.

The Rt. Hon. the Marchioness of Downshire.	The Rt. Hon. the Dowager Lady Kinloch.
The Rt. Hon. the Dowager Countess of Carnwarth.	The Hon. Lady Eliz. Moore.
The Rt. Hon. the Countess of Cottenham.	The Lady Louisa Cator.
The Rt. Hon. the Countess of Roseberry.	The Lady Jane Charteris.
The Rt. Hon. the Viscountess Combermere.	The Lady Dalmeny.
The Rt. Hon. the Dowager Lady Grey.	Lady Gipps.
The Hon. Lady Pepys.	Lady Morgan.
	Lady Nightingale.
	Lady Mary Singleton.
	Lady Palmer Ackland.
	Miss Burdett Coutts.

Treasurer.—John Parkinson, Esq., 66, Lincoln's-inn-fields.
Bankers.—Messrs. Coutts and Co., Strand.

This Institution has now been opened fourteen months, during which period a large number of patients from all the Metropolitan parishes, and from distant parts of the country, have been received. Although some deaths have occurred out of the 210 cases which, up to the present time, have been under treatment, *it is highly gratifying to report, that in several instances such relief has been afforded that many patients have been restored to their homes, and enabled to return to their usual occupations," etc. etc. etc.*

Really, the change from one to the other is quite pleasant. In his *second manner*, it will be seen, he begins by "join hands and down the middle" of the double row of noble Lady Patronesses of the Institution;—not a word now about this "hitherto-considered incurable disease," which conveyed the idea, that he had discovered its specific; not a word about "incipient cases discharged completely cured;" but we get instead, the strictly modest statement,—with which we find no fault,—that, "in several instances, such relief has been afforded, that many patients have been restored to their homes, and enabled to return to their usual occupations."

Of course, the innocent complicity of the Lady Patronesses in Dr. Marsden's scheme we can only lament. They know not what they do; we trust, however, that they are as amenable to a plain statement of facts as the Common Councilmen proved to be. After having pulled out such an ample stone as the 100 guinea grant for this Institution,—an Institution which it is so necessary to level for the good of Medical Science, and "*pour encourager les autres*" of a similar injurious tendency,—we have more room to introduce our hands, and, with the aid of the Profession, we doubt not that we shall in time bring the whole superstructure, *as at present based*, to the ground.

THE APOTHECARIES' LICENCE.

We understand, that it is the intention of the Court of Examiners of the Society of Apothecaries to make such modifications in their examination as will remove the difficulties now felt by gentlemen who are rather advanced in years, and who may wish to procure the licence of that court. We believe that surgeons in the Army or Navy, graduates of any British University, and members of the College of Surgeons who have attained the age of forty, and can produce evidence of a regular medical education, will be subjected to an examination on practical points chiefly, and will not be required to read Gregory and Celsus, or to possess the

knowledge of chemical minutiæ which is—wisely or unwisely we will not now consider—exacted from younger students. We think that this is a fair concession to the circumstances of many gentlemen who desire to settle as general practitioners, but who did not think it necessary to go up to the Hall in the earlier part of their career.

BITTER BEER.

We publish to-day a letter from Baron Liebig to Mr. Allsopp on the subject of the adulteration of Bitter Beer. It was owing chiefly to our instrumentality, that the extraordinary assertions of the French chemists were brought prominently before the British public; and we have, therefore, extreme pleasure in publishing the conclusive and satisfactory letter of the most illustrious chemist of the day. The investigations which have been undertaken by Messrs. Graham and Hofmann, and by Baron Liebig, are amply sufficient to reassure the public, and to prove that M. Payen, whatever may have been his grounds for the statement he made, was in total error. That either Mr. Allsopp's or Mr. Bass's beer is adulterated, we hold to be impossible. Moreover, although there is no direct evidence on the point, the reasons against the supposition that any kind of beer is adulterated with strychnine appear to be conclusive.

We cannot quit the subject without expressing our great satisfaction at the open and honest course adopted by Mr. Allsopp. We foresaw that the only way to avert the suspicions which the French statement excited, would be a full and complete investigation. In justice to Mr. Allsopp, we must state, that he has made this inquiry as strict and searching as possible, and has succeeded triumphantly in justifying himself and the important trade of which he is one of the principal members.

BYE-LAWS OF THE ROYAL COLLEGE OF SURGEONS.

The following Bye-laws of the Royal College of Surgeons, relating to the election and admission of members of Council, received the sanction of the Secretary of State for the Home Department on Tuesday last:—

1. The place and time appointed for every meeting of the Fellows for the election of members or a member of the Council shall be announced in the *London Gazette*, and in two London daily newspapers, not less than thirty days and not more than forty before the day of meeting.

2. Every Fellow desirous of a seat in the Council shall, within ten days from the publication of the *London Gazette* in which the day of meeting for the election shall be announced, transmit to or deliver to the Secretary of the College or person acting for him, a notice and declaration signed by himself in the following terms:—

I, A B, of C, Fellow of the Royal College of Surgeons of England, do hereby declare, that I am a candidate for a seat in the Council of the said College; that I am in the *bonâ fide* practice of the profession of a surgeon, and that I do not practise as an apothecary.

Together with a nomination signed by six Fellows of the College in the following terms, viz.:—

We, the undersigned Fellows of the Royal College of Surgeons of England, do hereby certify, that A B, of C, is in our estimation a fit and proper person to be a member of the Council of the said College; and we do hereby nominate him a candidate for a seat in the said Council.

And also a certificate signed by three Fellows, in the following terms, viz.,—

We, the undersigned Fellows of the Royal College of Surgeons of England, do hereby certify, on our own personal knowledge, that A B, of C, is in the *bonâ fide* practice of the Profession of a surgeon, and that he does not practise as an apothecary.

3. The names of the eligible Fellows (who shall have been nominated as candidates for the Council in the manner required, and who shall have complied with the provisions and conditions respecting the said notice and declaration, nomination and certificate,) together with the names of the six Fellows by whom they shall respectively have been nominated, shall be published in the *London Gazette* and in two London daily newspapers not less than ten days before the day appointed for the election.

4. Members of the Council retiring from office by rotation and desirous of re-election, shall intimate such their desire in writing, addressed to the Secretary or person acting for him, within ten days from the publication of the *London Gazette* in which the day of meeting for the election shall be announced; and the names of such members shall be published in the *London Gazette* and in two London daily newspapers, at the head of the list of the names of the several other candidates to be published as aforesaid.

5. At every meeting for election into the Council, not less than fifteen Fellows being present, the Chairman having declared the business of the day, the Secretary or person acting for him shall proceed to announce to the meeting the names of the several candidates so published as aforesaid, in the order in which such names were so published, except the names of such of the said candidates as shall previously have signified to the Secretary, in writing, his or their desire not to proceed to the election, whereupon a ballot shall be forthwith taken for the election of such number of members as shall be required to fill up the vacancies in the Council; and such ballot shall be kept open for three hours, unless for the space of ten minutes after notice from the Chairman of his intention to close such ballot, no Fellow shall actually ballot, in which case the Chairman shall declare such ballot to be closed; and at the expiration of such three hours, or on such previous closing of the ballot, as the case may be, the balloting-box shall be opened by the Chairman, who shall ascertain the result of such ballot, and shall forthwith declare the names of the Fellows elected into such vacancies, and thereupon the election of such Fellows to be Members of the Council shall be deemed complete. But if, after the result of such ballot shall have been so ascertained, and the names of the Fellows elected shall have been declared, it shall appear that the number of Fellows shall, from any cause, not be sufficient to fill up all the vacancies, the proceedings of the meeting shall be continued, and the ballot taken again, until all the said vacancies shall have been filled up by the election of sufficient Fellows for that purpose.

6. When there shall be any vacancy in the Council by the death or resignation of an elective member, the Fellow of those elected who shall have been so elected by the smallest number of votes shall be the substitute-member of Council in the room of such elective member; and when more than one such vacancy shall be required to be so filled up, the Fellow elected by the smallest number of votes shall be the substitute in the room of that member whose period of office would have first terminated, and so in regard to each of such vacancies respectively. And if it shall at any time happen that more than one member shall be elected by the same number of votes, being with reference to the other Fellows elected the smallest number of votes, the youngest in standing as a Fellow of the persons so elected by such equal number of votes shall be the substitute member; and so in regard to each of such vacancies respectively.

7. Every member of the Council shall, prior to his admission, subscribe his name to a copy of the bye-laws, in testimony of having engaged himself to the observance thereof; and upon his neglect or refusal so to do his election shall be void.

8. Every member of the Council shall, prior to his admission, pay twenty guineas; but which sum shall be paid on his first admission only.

REVIEWS.

On Diseases of the Liver. By George Budd, M.D., F.R.S.; Professor of Medicine in King's College, London, and Fellow of Caius College, Cambridge. Second Edition. 8vo. Pp. 486. London: Churchill. 1852.

The Medical Press of this country has never, perhaps, been more prolific than during the last quarter of a century; and though, among its numerous productions, we often find much to condemn, still we cannot but be sensible, that, notwithstanding the numerous temptations to acquire shallow and glittering rather than profound knowledge,—notwithstanding the disheartening encouragement so freely bestowed upon every quack and knave of the hour,—notwithstanding the patronage conferred upon every absurdity,—notwithstanding these drawbacks, and in spite of the anxieties and hardships of the honest medical man's career,—we still receive contributions to our literature, proving, that in our ranks are to be found many whose main desire is to mitigate

the pains and sufferings of our afflicted fellow-creatures, and to establish our daily practice on the firm foundation of scientific truth.

Dr. George Budd is known as a scholar, an accomplished physician, and an assiduous and successful teacher. In 1845 he published his work on Diseases of the Liver; and his reputation is now increased by the appearance of a second edition, in which our knowledge of the physiology and pathology of this gland is brought up to the requirements of the present day. Few diseases, as a class, stood more in need of investigation than those on which Dr. Budd has thrown the light of his experience; and we cannot but feel grateful to him for the use he has made of his former position as Physician to the Seamen's Hospital-ship, the Dreadnought, where he enjoyed opportunities for investigating the nature of diseases of the liver which rarely fall to the lot of practitioners in this country. At the same time, we must remember, that many of the difficulties which stood in the way of earlier observers had been removed by the publication, in the "Transactions of the Royal Society," of Mr. Kiernan's admirable papers on the anatomy and physiology of this organ, as well as by the subsequent researches of Bowman, Henle, and others.

The first edition of Dr. Budd's work is too well known to require comment or criticism from us; we shall, therefore, confine our observations to the new matter now brought before us, commencing by a few remarks on the state and relations of the organic constituents of bile,—to which the attention of chemists has, for the last few years, been actively directed. To make a perfect analysis of bile is a matter requiring great care and labour, and few complete analyses have been performed of human bile owing to the difficulty of procuring it in a proper form and in sufficient quantity; in the gall-bladder, also, the bile loses by absorption some of its more watery parts, and is further modified by the addition of the proper secretion of that cavity.

Fresh, healthy human bile, when taken from the gall-bladder, is found to be of a greenish-yellow colour, possessing a scarcely perceptible faint odour, a nauseous bitter taste, with a sweetish after-flavour, and a more or less viscid, unctuous feel, with many physicial properties in common with soap. It is heavier than water, that from the gall-bladder of the ox having a specific gravity between 1·026 and 1·030; it is often of an alkaline re-action, but if perfectly fresh is neutral. As it is found in the hepatic ducts it is less viscid, less bitter, and of a golden-yellow colour; and in such specimens Dr. Budd has never found plates of cholesterine, whereas in cystic bile they are numerous, being there formed by precipitation, or being derived from the coats of the gall-bladder itself. The analysis of this fluid generally referred to, and quoted by Dr. Budd, is that made by Berzelius of the cystic bile of the ox, which consists of

Water	90·44
Biliary matter, with fat	8·00
Mucus of the gall-bladder	0·30
Osmazome, chloride of sodium, and lactate of soda	0·74
Soda	0·41
Phosphate of soda, phosphate of lime, and traces of a substance insoluble in alcohol	0·11
	100·00

In subsequent researches, Berzelius separated from his biliary matter a green and a yellow colouring matter, a small quantity of fat and fatty acids, and a peculiar substance, which he termed biline, and which he regarded as the chief constituent of bile. This latter substance has since been found to consist chiefly of cholcic acid; and, in 1838, the opinion was promulgated by M. Demarçay, that the essential principles of bile consist of this resinous acid combined with soda, forming a substance analogous to soap. He consequently considered it to consist of little more than cholcate of soda.

Previous to these researches the biliary secretion was regarded as a much more complex fluid; and this appears to have been due to the fact, that the organic substance in combination with the soda is very readily decomposed:—

"It was found by Mulder," says Dr. Budd, "that when ox-bile undergoes decomposition spontaneously, or by the prolonged action of hydrochloric acid, it is resolved (with the exception of the fats, colouring matters, and salts,) almost entirely into three products—taurine, ammonia, and a substance which forms various acids, differing from each other merely in containing different proportions of the elements of water. All these acids pass into a well characterised acid, choloidic acid, (Demarçay), and as the ultimate product of decomposition into dyslysine."—P. 29.

After making a few remarks upon the ultimate composition of these substances, Dr. Budd continues:—

"Some researches on ox-bile, recently made by Dr. Strecker in the laboratory of Liebig, have given us more insight into its constitution. They have shown that the biliary matter which is combined with the soda (the cholcic acid of Demarçay) may be resolved into two acids, both containing nitrogen, and one of them containing sulphur.

"The acid that is free from sulphur (C_{52} H_{43} NO_{12}) may be further resolved into glycocol, the sugar of gelatine (C_4 H_5 NO_4), and an acid, which contains no nitrogen, to which Dr. Strecker has given the name, *Cholalic Acid*. This acid, which is the *cholic acid* of Demarçay (C_{48} H_{40} O_{10}), when boiled with strong hydrochloric acid, or when exposed to a high temperature, is converted, by the loss of part of its water, into choloidic acid, and ultimately, by a still further loss of water, into dyslysine.

The sulphuretted acid of ox-bile (C_{52} H_{45} NO_{14} S_2) may, in manner, be resolved into cholalic acid and taurine. It has, therefore, a similar constitution to its fellow acid, with taurine in the place of glycocol. When acted on by strong acids it yields taurine, choloidic acid, and dyslysine.

"If we use the simpler term, *cholic acid*, to express the cholalic acid of Strecker, the two acids above mentioned, of which glycocol and taurine are respectively the adjuncts, may therefore be termed, *glyco-cholic* and *tauro-cholic* acid. Tauro-cholic acid contains 6 per cent. of sulphur. Now, as the dried and purified bile of the ox contains only 3 per cent. of sulphur, it follows that, in ox-bile, glyco-cholic and tauro-cholic acids exist in nearly equal proportions. Dr. Strecker has further shown, that tauro-cholic acid and its compound with soda dissolves cholesterine very readily; while glyco-cholic acid has very little solvent action upon it. He has thus rendered it probable, that tauro-cholic acid is the chief solvent of the cholesterine of the bile."—P. 31.

A full account of the researches of Strecker will be found in Lehmann's work on Animal Chemistry, a translation of which is in progress of publication by the Cavendish Society.

As before remarked, few perfect analyses have been made of human bile; there appears, however, every reason to believe, that it resembles ox-bile in its physical qualities, and that on decomposition it yields the same products. The green colouring-matter of ox-bile has been shown by Berzelius to be identical with chlorophyl, the green colouring-matter of plants; and there is every reason to believe, that the brown bile-pigment of other animals is also a modification of this substance. As Dr. Budd well remarks:—

"The successive shades of blue, green, and yellow, which are seen in a bruise-mark on the skin, and which are so like the tints of the bile, long ago suggested the hypothesis, that the colouring matters of bile are derived immediately from the red colouring matter of the blood. Late researches tend to confirm this hypothesis, and thus render it probable that the peculiar colours of bile, urine, and blood, result from different modifications of the same pigment."—P. 34.

Many other important points are discussed in the introductory chapter, especially in reference to the facts, that the proper principles of bile are in great part derived, like those of the urine, from the waste of the tissues; and that the liver by its secretion purifies the blood, separating from it those noxious and effete matters which result from this waste. The debatable ground, as to whether the peculiar principles of the bile are formed in the liver, or whether they exist ready made in the blood, and are merely separated by this gland from it, is also entered upon, although no satisfactory data are given for the complete solution of so difficult a question. The chapter is closed by a discussion on the uses of the bile, followed by some practical remarks on the treatment to be adopted in those cases where, from different causes, the liver becomes inadequate to its office, a more abundant secretion of bile being requisite to purify the blood:—

"In the management of such cases we have two objects to fulfil; first, to enjoin those conditions and rules of life, that render a plentiful secretion of bile less needful; and, secondly, to endeavour to render the liver itself more active.

"The chief conditions to diminish the quantity of matter which the liver is called on to excrete, are, a light diet, with water for drink, active exercise, early rising, and a cool or temperate climate. Acids have been supposed to act in the same way, and

have been much in repute as a remedy in liver disorders, particularly in India, where, from the circumstances mentioned, a remedy having this mode of action is especially required.

"Various medicines seem to fulfil to a certain extent the second object, that of rendering the liver more active, and increasing in this way the secretion of bile. Mercury, iodine, the salts of soda, muriate of ammonia, and taraxacum, have undoubtedly an action of this kind. The first and last of these medicines, especially, have long been in this country the chief resources of the physician in the treatment of chronic hepatic disorders. The marked temporary benefit often resulting from mercury given for this effect has, from the difficulty of distinguishing the various diseases of the liver, and the consequent indiscriminate use of the drug, led to great evils. This medicine was at one time, by English practitioners, given almost indiscriminately, and long persevered in, for disorders of digestion, many of which did not depend on fault of the liver at all, but on local disease of the stomach or intestines, or on faulty assimilation, the result of debility, which the prolonged use of the mercury but too often increased."—P. 51.

The limits within which it is necessary to confine this review, prevent our following Dr. Budd through the successive divisions of his work with that minuteness which we could desire. We must, therefore, pass by the chapters on Congestion of the Liver, on the Inflammatory Diseases of this organ, on the Diseases which result from its Faulty Nutrition or Faulty Secretion, and on its Cancerous Diseases, in order to notice briefly the section devoted to the consideration of Hydatid Tumours, which, like cancerous growths, are more common in the liver than in any other organ, but the nature of which we do not think is as clearly understood. These tumours in the liver consist of a sac of variable thickness, formed of condensed hepatic tissue, with the remains of obliterated vessels, and lined by a thin membranous bladder or cyst, containing a colourless, limpid fluid, in which are generally found floating a variable number of similar globular bladders, of sizes varying from a pea to a walnut, or even larger. To these bladders, Laënnec gave the name Acephalocyst—a bladder without a head (ἀκεφαλὴ κύστις). The acephalocyst, lining, but not adherent to the sac, is composed of finely laminated, friable coats, about the firmness of coagulated albumen: its layers can only be distinguished by the microscope. Sometimes (almost always in the lower animals,) this cyst contains no floating hydatids, or only a very few; in other cases it is literally crammed with them; and these, again, it is said, may contain another generation. To distinguish these different kinds, as well as to mark the mode of their increase, naturalists have divided these productions into two species: 1st, the *acepholocystis endogena* of Kuhn, likewise called *socialis, vel prolifera*, by Cruveilhier; the "pill-box hydatid" of Hunter, which is the kind most commonly developed in the human subject, and in which the fissiparous process takes place usually from the internal surface of the parent cyst, the progeny being sometimes successively included; and, 2ndly, the *acephalocystis exogena* of Kuhn, *eremita vel sterilis* of Cruveilhier, which developes its progeny generally from the external surface, and is found in the ox, and other domestic animals.

In reply to the question, What is the nature of hydatid tumours, and how do they originate? Dr. Budd remarks:—

"By some, acephalocysts were supposed to be true parasites, having independent vitality, and propagated by germs introduced from without. By others, they were supposed to result from depraved nutrition of one of the normal constituents of the body. A few years ago, this latter opinion was expressed in more definite terms by the most eminent of our anatomists,(a) who imagined them to result simply from unnatural development of the nucleated cells, which perform such an important part in the nutrition and growth of all organised bodies. The question seems at length in the way of being settled by the interesting discovery to which attention has lately been recalled by a French physician, M. Livois, that acephalocysts are the dwelling place of those microscopic animalcules to which Rudolphi gave the name *echinococcus*, from the cylinder of hooks which surrounds the head. It has long been known that echinococci occasionally exist in countless numbers in acephalocysts; but such instances have been regarded as exceptional, and the echinococci have been regarded as parasites of the hydatids. The researches of M. Livois, however, have led him to the conclusion, that these animalcules exist in all acephalocysts.

He states, that among more than eight hundred hydatids from man and other animals, he did not meet with a single one without them."—P. 417.

Dr. Budd confirms these observations, which we can also do from some researches on a smaller scale. At the same time, we believe these views are not universally entertained by anatomists. The effects, symptoms, diagnosis, and treatment of these tumours, are then fully described; and the work concluded by a chapter on Jaundice, which, though only a symptom of disease, (*i.e.*, of some impediment to the flow of bile into the duodenum, and the consequent absorption of the retained bile, or of defective secretion on the part of the liver, so that the principles of the bile are not separated from the blood,) is, nevertheless, such an important and frequent symptom, that it well merits separate consideration, and forms, as it were, a useful summary of the whole work.

From the foregoing remarks, our readers will perceive the high value which we set on Dr. Budd's work; we will only, in conclusion, add a word of praise to Dr. Beale, for some excellent chemical analyses performed by him for the author; to Dr. Westmacott, for some graphic illustrations; and to the publisher, for the beautiful way in which the work is "got up."

GENERAL CORRESPONDENCE.

EVIDENCE OF DR. M'WILLIAM ON THE YELLOW FEVER IN THE ECLAIR AT BOA VISTA.

[To the Editor of the Medical Times and Gazette.]

Sir,—That part of the Second Report on Quarantine by the General Board of Health which refers to the alleged importation of yellow fever into Boa Vista in 1845 has, it appears, given much umbrage to Dr. M'William, the promulgator of this story of contagion.

The doctor had imagined this matter had long since been at an end, (though, on the presentation of his Report on the case, his medical chief, who probably took the trouble to examine the value of his so-called facts, condemned his conclusions,) because *three* reviewers, representing in this instance "the united voice of the Medical Press, with one exception," in Great Britain and America, confirmed, as he considers, the justice of those conclusions.

One feels inclined to ask, whether Dr. M'William ever heard of the manner in which, of necessity, from his manifold engagements, a reviewer reads a book; and, further, whether he ever felt the force of the expression, "silent contempt."

If I remember aright, Sir, it was once observed by the immortal Cherviu, that, if you believed the statements of M. Pariset to be true, you must be a contagionist; but, when you became aware that the statements of the latter gentleman were altogether false, you would become of a totally different opinion on the question at issue. So, in the present instance, I take it, that, while these representatives of "the united voice of the Medical Press" believed that the conclusions of Dr. M'William were founded on evidence, they could not avoid believing, also, that such conclusions were sound; but I submit that it becomes a different matter when the careful analysis given by Dr. Browne in the Appendix to the Report of the Board of Health, proves beyond all question, that there is nothing furnished by Dr. M'William which any Court of Judicature, or any man of common sense, would accept as evidence at all. It literally is not worth a rush; for the leading witnesses contradict each other, while they are chiefly selected from an interested class of low Portuguese, never celebrated for a regard for truth.

After reducing "the united voice of the Medical Press" to four for want of space,—not being able to find room even for reference to the others,—Dr. M'William amuses us with a reprint of the opinions of a Board of Officers assembled at the office of the Army Medical Department, 1849-50; and also with an opinion from a Committee of the College of Physicians: but, as no examination made by either of these bodies of the papers relative to the Eclair is given, we have no means of knowing that they did not each also take for granted that the stories collected by Dr. M'William were worthy of the name of evidence.

We are not informed whether any examination of medical men conversant with the disease was made by the latter body; nor the grounds on which a majority of the former gentlemen delivered opinions directly at variance with the greater part of the medical evidence taken by themselves; nor whether *their* Director-General entertained any decided views on the subject. If he did, the perusal of pp. 130-31 of the "Second Report on Quarantine" will materially modify our opinion as to the value of an inquiry from

that source; especially when it is observed, that no medical officer of the first rank, of which there must be many unemployed, was upon the Board. The members were all subordinate officers, eligible for promotion on the favourable recommendation of their superior; or liable to service in a tropical climate, did he imagine their experience on the subject insufficient.

Without questioning the competency of other bodies, the nation must be much indebted to the gentlemen who have undertaken the labour of sifting such a mass of contradictory rubbish as the examinations on which Dr. M'William's conclusions were founded.

I need hardly say, that the time has passed when the public is to be called on to bow before the dictum of any College, Board, or Review whatever, on a question of so much importance to international intercourse as Quarantine. It has been too much the practice to settle such matters by simple authority; and, if the whole voice of the Medical Profession were agreed, the public would nevertheless demand reasons, and very efficient reasons, for the conclusions at which they had arrived.

Dr. M'William, in his "Observations," unnecessarily confuses the subject, by prominently introducing the question of contagion. But the present question is, not whether the fever of the Eclair was contagious, but simply whether it was imported into Boa Vista. After having read the evidence adduced, not in the light of any theory of contagion or the contrary, I must confess to be one of those who consider that Dr. M'William has failed to prove his allegations. I have read his official reports, and, on such loose statements, people could launch any theory. If there be any considerable number of medical men who are convinced by such statements, the worse for the character of the Profession, and the more need for including the study of logic in the curriculum.

Dr. M'William ought to be well aware, that the introduction of names to back opinions is of no use. It only proves what the parties thought, not what was true. I could overwhelm him with names. Has he, then, in his Official Report, made out his case? I at once say, No! Even in his "Observations," (*Medical Times and Gazette*, p. 542,) he admits what is tantamount to a giving up of the whole question. Probabilities may be very well in discussing scientific questions, but they cannot be admitted as weighing against the evils and cost of Quarantine.

The best way to decide these cases would be, to bring all the witnesses, medical or otherwise, before a legal tribunal, to sift the facts, and reject the opinions. This constitutes the value of the Report of the General Board of Health. It is not a medical Report, but simply an examination as to the credibility of testimony.

Dr. M'William now adduces new matter as evidence. That is, matter not official, which cannot be admitted into court.

If the Board of Health had done nothing more than call in question the complacent conclusions of bad observers, it would merit eternal gratitude from the Medical Profession as well as from the public.

The error committed by Government in the Eclair question was in not sending out two or three clever barristers to ascertain questions of fact. They would have disposed of Dr. M'William's 1600 replies in a very summary fashion. Even the Doctor's new version and evidence in these "Observations" is fatal to the whole inquiry.

As to the fever at Porto Praya, there is difference of opinion admitted, and the Board of Health were quite justified, considering Dr. Stewart's high position, in preferring his testimony to the bad evidence of Dr. M'William.

It is perfect burlesque to talk of the "clear and satisfactory adjustment" of points which our complainant settles at once on the authority of his own assertions, backed by his friend John Jamieson, (a convenient witness, by the way, and most conveniently at hand,) against any amount of respectable evidence which can be adduced.

For myself, I confess that I am unable to discover at what the good Doctor is driving. Does he wish to prove that the disease at Boa Vista was a disease *sui generis*, or not? If an exaltation of the endemic remittent, as he affirms, of what possible value are his puerile contradictions of its existence at the same time at Porto Praya? If he is right on this point, the College of Physicians, Sir William Burnett, some, at least, of the army medical officers, Dr. King, Captain Simpson, and a host of others, besides the Board of Health, agree with him. But, if it was a disease *sui generis*, Dr. M'William must resign the glory of the discovery to the disciples of the now illustrious Chisholm, and Dr. Nunes.(a) For the Chisholm school have always contended that the endemic remittent is not contagious.

By the way, it were well that we should be informed whether Dr. M'William considers small-pox may be non-contagious at one place, contagious at another, and again non-contagious at a third; or prevail only during the usual endemic season, as in the case of the Eclair fever at Boa Vista?

Mr. M'Clure's case falls under the same class as those of the guards at the fort. Moreover, the Growler herself had fever on board, and two cases from her actually died in the Woolwich Infirmary.

As to the overcrowding at the Fort, Sir William Burnett has already, as quoted in the Report on Quarantine, expressed an opinion, that it was capable in itself, at least when coupled with the intoxication and high temperature, of producing a fever of the worst kind, in which black vomit and yellowness of skin would be prominent symptoms. Did Dr. M'William really never hear of the "Black Hole" at Calcutta?

I need hardly tell the readers of the *Medical Times and Gazette*, that the influence of sanitary conditions on the propagation of epidemics is now known in this country, far beyond the limits of the Medical Profession; and it behoves all medical men writing on such subjects to be fully acquainted with them. So long as the hypothesis of contagion is used as a kind of "*pons asinorum*," to get over the difficulties of a more searching inquiry, so long will false opinions be afloat, and commerce have to pay their cost.

But as to the fever at Porto Praya, and the epidemy among the cattle,—can it be imagined that the bare assertions of an officer, without any evidence beyond inquiries among the class of persons on whom Dr. M'William appears, according to his own confession, to have relied, will be deemed sufficient to overbalance the testimony of his superiors in age, rank, medical and official experience? Or that an "intelligent and keen observer," a civilian residing at St. Nicholas, will outweigh the recorded observations of a naval commander, reported soon after his arrival from the scene in question, which happened at Porto Praya in 1845? Or that the veracity of John Jamieson(a) is to disturb the balance when weighed against the evidence of Dr. King?(b)

In the second portion of his "Observations," Dr. M'William lays great stress on the unfairness of supposing, that, if the Eclair fever was contagious, fomites must have been capable of introducing it into Boa Vista. But, in his alleged case of importation into Bahia in 1849, (see *Medical Times*, 19th April, 1851, p. 424,) the whole story *originally* rested on the supposed introduction by fomites from the captain of a ship,—having then, at least, no cases on board,—who had been about a month in the town before the appearance of the first case, and was himself never affected. And I mention this to show the utter impossibility of fixing this careful, laborious, and distinguished observer, to any one point. For, in 1851, as in 1852, show him the untenable nature of any particular piece of evidence, and, "presto, change!" he immediately produces a different version.(c) The disease is exalted endemial remittent, yet was never seen at Boa Vista before; at Brazil, it may be communicated from the jacket of a healthy sailor, but the inhabitants must be actually sick to convey it from Boa Vista; and the foul linen of the "Hankey" and the "Dygden," which so long befriended the contagionists of former days, is thrown overboard in more ways than one(d) by the skilful examiner of the "Eclair."

(a) The estimate of the value of Dr. Almeida's opinion would appear to be from the pen of Dr. Gillkrest, not Dr. King.

(a) The credibility of this immaculate witness is illustrated by the following story, related to me some weeks since by Dr. King:—

In the year 1846, reports reached the Admiralty of a second severe outbreak of fever at Boa Vista, and Dr. King was despatched to the relief of the distressed inhabitants. On the passage out, the Sphynx, in which he sailed, touched at Madeira, where the reports concerning Boa Vista were confirmed. Again, at St. Nicholas, Captain Cragg was assured, that the fever was raging on the island of Boa Vista to a frightful extent. Arrived at the harbour of Porto Sal Rey, a boat put off from the shore, containing this very John Jamieson, who, on being questioned by the captain and Dr. King, declared, that the people in the town and on the island were dying off in great numbers. Dr. King at once left the ship, and, on arriving at the port, found—what does the reader think, who relies on the veracity of John Jamieson?—*two* cases of fever, one of which was rheumatic, in the whole town! And the Doctor subsequently found, during his stay of upwards of a month, 14 or 15 slight cases within the circumference of the island.

(b) The epidemy among the cattle is very happily disposed of by Dr. M'William and his friend Jamieson; but, as the same causes exist every year, it may be well to inquire whether the epidemy be of annual recurrence? On his opposite tack, the Doctor appears to *doubt* any great mortality, because he did not observe (and "no place could escape *me*") the cattle lying dead; but, as dead animals are usually buried, or cast into holes,—without the nose of a carrion crow, they might escape even the most diligent of doctors.

(c) "*Since this paper was written*," (and since the discussion at the Epidemiological Society also.) "I have heard from Dr. Paterson's brother, (etc.,) now in this country," (our Doctor is never without a witness at hand,) "that the case of the Brazilian boy, though his brother's first case, was not the first case in the town"—*Medical Times*, p. 424 (1851).

(d) "So that in none of these cases" (the washerwomen) "can the occurrence of fever be fairly attributed to infectious matter conveyed by the linen."—Dr. M'William's "Report," p. 82.

"*I have since ascertained*," (indefatigable inquirer!) "that the gunner's

Nobody finds fault with the generosity of Great Britain in relieving the necessities of a poor Portugnese settlement; but they do complain of alms, whether needed or not, being obtained under false pretences.

Nobody doubts that Dr. M'William made excellent use of his "very useful and willing assistant," John Jamieson; or that both these philanthropists worked very hard to obtain the end they finally gained.

It would be a perfect waste of time to handy further about evidence, for Dr. M'William evidently does not understand the meaning of the term. The fact of his witnesses contradicting each other does not detract from the value of their testimony one jot in the Doctor's estimation, who considers such discrepancies very natural and highly satisfactory; indeed, they would appear to make the conclusions more valuable. In very truth, here is a Daniel come to judgment!

Then, again, the evidence seems much enhanced by resting on the foundation of the Doctor's 1600 questions,—and, with some exceptions, his 1600 answers; for, let it be remembered, the queries were for the most part put to illiterate Portugnese, whereas the replies appear in the very best of the Queen's English, on the interpretation of Dr. M'William and his friend, who are thus self-constituted counsel, witnesses, judges, and reporters. But it has been well observed by Mr. Howell, that the value of evidence depends on the credibility, not the extent, of the testimony.

Nobody has denied the comparative healthiness of Boa Vista immediately before the arrival of the Eclair. It is equally undeniable, that local causes existed on the island sufficient to have produced fever(a) had the Eclair never touched there.

With reference to the vessel herself, after all the egotistical lucubrations of Dr. M'William, there remain—

1. The boating at Sherboro.
2. The rainy season and drunkenness at Sierra Leone.
3. The green wood taken on board for fuel.
4. The thermometer at 86°.
5. The putrid mud under the boilers.
6. The overcrowding and increased drunkenness at the Fort.
7. And the final sacrifice of seven lives to the quarantine regulations of Great Britain.

While, as to the inquiry, there remains the fact, that not only Sir William Burnett, but Dr. King, who examined the circumstances at Boa Vista, and reported officially upon them, and who is, to say the least, as able an officer as Dr. M'William, arrived at the conviction, that Dr. M'William was wrong in all his conclusions.

I am, &c. THOM. BAKER.

St. John's-road, Fulham.

[After our article on the Report of the Board of Health was in type, we received Mr. Baker's letter. It has not induced us to alter a single word of what we had previously written; but it has still further excited our disgust at the manner in which the Board of Health are attempting to set aside the most important evidence that has ever been adduced in support of the contagion of yellow fever. We shall not enter, at present, into the argumentative merits, or rather, demerits, of Mr. Baker's letter. We shall now only remark, in the first place, that we consider the proposal to send out barristers to investigate a medical question, to be of a piece with that philosophy which has made barristers both head and tail of the Board of Health; and, secondly, we must inform Mr. Baker that, knowing nothing of Dr. M'William, we analysed his Report, when we received it, with as much care and anxiety to arrive at the truth as any barrister could have bestowed on it, and that we are prepared to uphold the conclusions we arrived at against Mr. Baker and all the gentlemen of the long robe together.—ED. *Medical Times and Gazette.*]

clothes were not taken ashore. Those who know anything of men-of-war are aware, that the clothes of the crew are washed and scrubbed on board."—*Medical Times and Gazette*, p. 541 (1852).

Surely this is a second edition of Cafliero and Villalunga!

(a) "But the soldiers had, only a week before they were seized with fever, come from Porto Sal Rey, where, at least in a theoretic point of view, the condition of the soil, during and after the rainy season, is such as may cause fever. Assuredly many bad fevers have been attributed to less obvious causes."—Dr. M'William's "Report," p. 105.

Lind, some eighty years ago or more, warned navigators against remaining at Boa Vista in the rainy season.

"The heat is extreme from November to July, and for the rest of the year storms and fogs are prevalent, and the climate is exceedingly unhealthy."—M'Culloch's "Geological Dictionary," Article, Cape de Verd Islands.

EXTRAMURAL INTERMENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—As you have kindly taken upon yourself the advocacy of the abolition of interments in populous places, on account of the unhealthful tendency of the practice, I venture to offer you a slight sketch of the history of the burial of the dead in this country, which may not be uninteresting to your readers.

This practice, which has such an evil tendency, is peculiar to Christian countries; and its introduction seems to have arisen from the circumstance of the clergy being interred within the churches or monasteries to which they were attached while living, or in chapels built as monuments to perpetuate their names. Persons of note, such as kings and nobles, and others of distinction, claimed a licence to be thus interred; then the wealthy purchased the right of burial within the Galilee and the church; and the poor then were interred within the precincts of the boundary, as being considered most sacred (next to interment within the walls) for such a purpose as the depository for the remains of the dead. But this system of interment early grew into a custom, fraught with many evils to the health of the living; and there were many edicts, and other prohibitory Acts, passed to prevent interments in populous districts, accompanied with heavy penalties for any infringement of the law; while, in the United Kingdom, the Government, till the subject was forced upon them by Mr. G. A. Walker, never interfered in the matter, from an apprehension on their part, that they would be interfering with the vested rights of the clergy.

The proximity of the graves to the churches, afforded the clergy great facilities in performing the rites for the dead, and contributed not a little to the introduction of intramural interments as a general custom; and the emoluments arising from the burial, together with the vanity or religious enthusiasm of relatives, assisted to continue this system of interment, fraught so much with evil and disease.

Evelyn (speaking of the great fire of 1666, "Sylva,") says: "I cannot but deplore, that when that spacious area was so long a rasatabula, the churchyards had not been banished to the north of the walls of the City, where a great inclosure, of competent breadth, for a mile in length, might have served as a universal cemetery to all the parishes, distinguished by the like separations, and with ample walks of trees, the walks adorned with monuments, inscriptions, and titles apt for contemplation and memory of the defunct." Nearly two hundred years have passed, and yet little has been done to raise the subject of interment of the dead in the midst of the living beyond the standard of speculation or private enterprise.

In 1814, the then Commissioners of Improvements of Westminster reported to Parliament that St. Margaret's churchyard could not, consistently with the health of the neighbourhood, be used much longer as a burying-ground, for that it was with the greatest difficulty a vacant place could, at any time, be found for strangers; the family-graves, generally, would not admit of more than one interment, and many of them were too full for the reception of any member of the family to which they belonged. The churchyards are, many of them, raised several feet above the level of the adjoining streets by the continual accumulation of mortal matter; and there are others in which the ground is actually probed with a borer before a grave is opened. The refuse of the churchyards are disposed of either "as bones," which are sent every opportunity to be crushed in the mills of the North for manure, or by fire, when "the flesh" is actually destroyed in masses taken from the "decayed and fresh corpses," and the "coffin-wood is used as fuel" to consume the pestiferous mass; this is done nightly in densely populated districts. Yet, with all this clearance, the number of the dead increases in such frightful disproportion to the space allotted to them, that it is a matter of serious thought whether, without any enactment, the magistrates of each district could not interfere and prevent the injury done by the burial of the dead, under such circumstances, so unfavourable to health. Scenes like those described are alike revolting, whether considered with regard to the decency and respect with which the surviving friends desire that the remains of the dead should be treated, or considered in regard to public health, and have led to that attention being drawn to the matter which otherwise might have remained unminded still longer; but the passing of the Act for a General Cemetery Company, in 1832, changed the public mind from the facts, that the poor could not pay the high rates of charge exacted at the cemetery, and that they must still be interred in the Metropolis, and perpetuate the evil. The rich do not live in the vicinity of the grave-yards, but they often take their seats in churches ventilated through the vaults in which the dead are decaying, giving to the living a lesson of pestilence at prayer-time. Yet the poor live, and disease is created, year after year, in the

neighbourhood of the grave-yards, under the names of cholera, fever, etc., or any other epidemic which the effluvia therefrom may cause. The number of cemeteries has increased, and there are six chartered companies now in existence; yet it was not till Mr. Walker took upon himself the arduous and ill-requited task of proving that we were creating a pestilence around us by the practice of the interment of the "dead in the midst of the living," because the evil which Mr. G. F. Carden thought could be remedied by private speculation in cemeteries, after the model of "Père la Chaise," only increased the number of grave-yards, without advancing the object intended, of decreasing the number of burials in the Metropolis, from the heavy expenses attendant on the funeral; and the heavy charges incurred at the cemetery, which are far beyond the limited means of the poor, who incur two taxes thereby,—that of the old parish fee, as also the new ground,—are preventives to many persons.

The new scheme for a cemetery at Woking-common, as the "Necropolis," may be but a perpetuation of the evils of heavy charges and high remuneration for the shareholders, and will require the strict surveillance of the Government, both in their valuation for purchase, and the limits of the schedule charges for interments.

In all other countries, the burial of the dead is in the Government; in this country, it is in the possession of those whose business it is to make great overcharges, and preclude the possibility, with many, of even decent interment.

The great pestiferous evil is, I trust, about to be remedied, and the charges for interment will be regulated by a scale at once fair and moderated to the trouble given, not left to the mercies of the undertaker or speculator.

Excuse the length of my communication; yet it is but the mere heads of the subject, as considered relatively with the many and persevering attempts made at different times by philanthropic individuals, who perceived the destructive tendency of the custom of intramural burial, and sought to prevent, by some means, a repetition of the annual malaria caused by the practice; and it has been found that, even while in the hands of the Government,—even in the hands of the Ministry,—pecuniary and private interests have stepped in to mar a public good, and the general health might have been sacrificed for private benefit or emolument.

I am, &c. WM. J. HUGHES.

MEDICAL PROVIDENT INSTITUTIONS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Though I am no controversialist, and, if I were, though I have no disposition to enter the arena with Mr. Grainger,—yet I do think it desirable that men should be able fully to make up their minds as to the kind and degree of support which they ought to give to the several schemes now afloat for the benefit of medical men or their families. Of these, a general impression seems to have got abroad, that the British Medical Fund will not be able to keep its ground, and that it will give place to its more fashionable junior, the Medical Benevolent College. I confess I shall see its extinction with regret, for, although it originated in miscalculation and error, and although the supposed benefits of its originator, Mr. Daniell, had no foundation in fact; yet, when it was taken up in a business-like manner by Dr. Forbes and others, I heartily wished it success as a good provident institution, and as such supported it. As a quiet looker-on, I regret it should be superseded by an Institution which promises highly, but which I do not think calculated to be useful in nourishing and educing provident habits. You see, Sir, that I place the Medical Benevolent College under the head of "Provident Institutions," and, as such, class it with the local provident institutions of the kingdom, with which it is more nearly allied, and with which it has been recently proposed, by Dr. Soulby, that it should be in some measure amalgamated. Now, perhaps, I shall be here met with a flat denial; but it will be seen, that its constitution is really such, and that in one way or other its advantages will be given, not to the most distressed objects,—not to any who have not fifteen pounds a year; and that this annuity can only be conferred by election—by election of subscribers at large—thus subjecting the candidate to all the degrading process and anxieties of a canvass, and introducing the traffic in votes, the bartering of votes, the purchase of votes, and finally giving success to those who have the largest number of friends, and of wealthy friends, at command. I confess I cannot look upon these results without pain, because, by a misnomer, the charitable mind has been taken away from the only really benevolent fund in the kingdom, and has given its aid and its influence to a fund which contains within itself the elements of so much painful feeling. I do not wish to put these two institutions in opposition; they admit not of comparison; and, though they may go on together, the latter Institution will always be found necessary to relieve the truly destitute, or the parties suffering from temporary distress, who cannot be relieved from the College. It is to be remarked, that all the support afforded to the Benevolent College is not purely disinterested. Within my own knowledge, one gentleman has avowedly exerted himself in its favour, in order that he may stand well with the Committee, and gain such influence with them as may be useful in obtaining for his children the benefits of education. But, for a moment, let us consider the question of annuities. And here it may be remarked, as in a recent paper of the Benevolent Fund Committee: "That it must be obvious to every reflecting being, how infinitely superior are the blessings conferred by these small annuities, enjoyed at home, and surrounded by all the charities of life, to those which could be obtained in any other less private way, and without these advantages." In fact, the attempt at centralisation in the Benevolent College is to be looked upon as an evil, not as a good. Human nature is the same everywhere,—imperfect; and experience has shown, that these asylums are, in fact, anything but the little heavens upon earth which are represented, and that they commonly form the nuclei for jealousies and ill-will in a thousand different shapes, which embitter the lengthening shadows of the evening of life, and that, though they may furnish bread and exterior comforts, they are mingled with the wormwood and the gall of irritated feelings, roused into action by the provocatives of society. The Benevolent College, with all the kind feelings of its most worthy projectors, is, in fact, attempting too much, and would have been more useful and more efficient had its objects been more limited,—had it, for instance, been confined to an educational establishment. Now, with its present multifarious objects, it will require an enormous outlay to complete the necessary buildings; and its present collected fund of 10,000*l.*, however liberal, will be small, compared with the sum that will be required; after which comes the necessary endowment to secure the annual income, which must be permanent, and not dependent upon annual subscription, which cannot be relied upon after a few years. Mr. Grainger's admiration of the Benevolent College arises from the multitude of its objects; my own apprehension of its ultimate failure arises from the same cause. True, that it professes to provide a home for the widow, or the disabled, worn-out practitioner, if they have 15*l.* a-year to live upon; but how many there are who have no such sum, those only can tell who are familiar with the distress brought constantly before the Benevolent Fund,—after all, the only fund which can relieve the casualties of life—which can provide for temporary distress, which can reinstate the ruined man in a position of self-respect, and restore him to provide for his own family,—which can assist the widow in her exertion to support herself and orphans—which can aid the education of these orphans without ostentation, and which can shed the blessing of annuities upon the hearth of home, and in the narrow circle where grow the moralities of life. Think not, Sir, that I am opposed to the Benevolent College; I wish for, and would forward, its success. But, while I see so many individuals bruiting its advantage, I do wish that the *audi alteram partem* should be observed, and that men should not give themselves *tête baissée* to its support, without having the opportunity of considering, that the plan before them is not perfection; and of deciding, whether it is not in their power to approach nearer to that most desirable attribute, or of realizing more of its power, by attempting less.

Far be it from me to damp the ardour of pursuit in any of the friends of the Benevolent College; but it is my duty to remind them, that there remains a purely charitable, unostentatious institution, which, for seventeen years, has gone on quietly, diffusing its blessings around it—without an expensive establishment—without large funds; but earnestly applying those funds with the one simple object of doing all the good they can accomplish in the sphere within their reach. It is my earnest desire, that every individual contributor to each of these institutions should also contribute to the other; and sincerely do I deprecate, that any one should excuse himself from such subscription, by the fact, that he had contributed to the other. Let every one subscribe to the Benevolent College, because he has been charitable in aiding the Benevolent Fund. Let every one subscribe to the Benevolent Fund, because he has been provident in aiding the finances of the Benevolent College. I am, &c. W. NEWNHAM.

SKODA'S THEORY OF CONSONANCE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have read with surprise, in your Number for May 8, an article by Dr. Walshe, controverting Skoda's theory of bronchial

respiration and bronchophony, in a way showing, as I think, a misconception of the meaning of that distinguished auscultator in his use of the term consonance. It is well known, that when a distinct note is sounded, a vibration is often set up in any body in the neighbourhood, such as a tight string or enclosed column of air capable of sounding in unison or in the harmonic of that note, and thus an independent repetition of the sound is produced that may even be louder or continue longer than the original. It is also well known, that the box of the guitar, violin, or piano, by inclosing a body of air which sounds along with the strings, increases the intensity of the sound; also that the human voice, or any other sound is rendered louder in a roomwith solid walls than in the open air or in a tent, etc. All these phenomena are included by Skoda under the term consonance. Whether they are all fundamentally the same in origin, I must leave it to those more learned in mechanical philosophy to decide; and it is not very clear what Skoda's opinions are on that point, but he rather speaks as if they were. At any rate it is in that wide sense that he uses the term.

But in arguing the question, Dr. Walshe restricts Skoda's meaning to the first alone, namely, that in which there is an independent focus of repetition of the sound, and certainly succeeds in raising considerable difficulties in the way of its being a complete explanation of the phenomena of bronchophony. However, in attempting to solve these difficulties himself, he is obliged to fall back (at, 2ndly, p. 462) upon the principle of reflection, which apparently does not differ at all from what is included by Skoda under the term consonance.

Taken in its broad sense, I do not think Dr. Walshe has shaken Skoda's position, "that the varying conducting power of the healthy and diseased lung-substance cannot be taken as a basis of explanation of the auscultatory phenomena of the respiratory organs," as opposed to the theory of Laennec, who makes that circumstance a cardinal point in his explanation of many of the phenomena of anscultation. It would take up an unwarrantable portion of your time and space to go into all the arguments on both sides; but I may just allude to one which Dr. Walshe overlooks, and which appears all but decisive—namely, that founded on the occurrence of bronchial respiration in a hepatized portion of lung. The common explanation of that phenomenon—namely, Laennec's—is, that the solidified lung being a better conductor of sound than the healthy tissue, allows the rushing of the air through the bronchial tubes to be more distinctly heard. Now we know, that the more any portion of the lung is capable of expansion during inspiration, so much the quicker and stronger must be the stream of air through the bronchial tubes of that part; but it is precisely when the cells of the lung are impervious to air in a hepatized portion of lung, and therefore no perceptible stream of air can be passing through the bronchial tubes, that the bronchial respiration is heard. This is apparently quite decisive against the theory of conduction. The explanation of Skoda is as follows—(Die Percussion und Auskultation, 1st Edit., p. 81)—"When the walls of the bronchia ramifying in the portion of the lung-substance become sufficiently solid to reflect the sound, the respiratory murmur of the larynx, the trachea and the bronchi consonates in the air contained in the bronchial tubes so situated." In fact, the bronchial ramifications in a hepatized portion of the lung become, for the time, an instrument like the speaking-trumpet, or the sounding-box of the guitar or violin. I am, &c.

Liverpool. J. Drysdale, M D.

ENTROPIUM.

[To the Editor of the Medical Times and Gazette.]

Sir,—I have read with great interest an article on "Entropium," in your last number, by Mr. Haynes Walton. Although I do not, by any means, agree with the talented writer, that entropium invariably depends on one and the same cause, namely, erroneous muscular action, yet I have long been of opinion, that entropium is dependent, in many instances, on excessive and faulty action of the orbicularis muscle. ("Treatise on Diseases of the Eye," London, 1835, Vol. II., p. 795.)

In my treatise on the diseases of the eye, I have treated very fully of the various forms of entropium, and have described, as a leading variety of the disease, that which Mr. Walton represents as its sole form. Having, in various other parts of my treatise, represented the frequent occurrence of entropium, (temporary or permanent), in consequence of erroneous and excessive action of the orbicularis muscle, and suggested operative proceedings, founded on this view of the pathology of the disease—operative proceedings, the same in principle as those suggested by Mr. Walton, I do not think he should have omitted all reference to my views and opinions.

I will conclude my communication with the following extract:—

"*Entropium produced by Spasm and Hypertrophy of the Orbicularis Muscle.*—Sometimes the orbicularis muscle is irritable and spasmodic in its action, or, from an increase in its volume, its power may be much augmented. A spasmodic state of the orbicularis palpebrarum is generally produced by an increased sensibility of the retina to light, and ceases on the restoration of the natural sensibility of this delicate texture; so that the treatment of entropium, thus produced, is, in fact, but the treatment of the ophthalmia with which it may be associated. The method of curing entropium arising from hypertrophy of the orbicularis muscle, consists in cutting through the palpebral integument quite down to that muscle, and removing with the curved scissors a portion of its fibres corresponding the extent of the entropium."—*A Treatise, etc.*, Vol. II., p. 795.

It will thus be seen, that, in the year 1835, I described a frequently-occurring form of entropium dependent on increased power and on erroneous action of the orbicularis muscle, and suggested, as the surgical remedy adapted to the cure of the disease, the removal of a portion of the fibres of the muscle.—I am, Sir, &c.

Birmingham. Richard Middlemore, F.R.C.S.

CHLORIDE OF ZINC PASTE IN FISTULA IN ANO

[To the Editor of the Medical Times and Gazette.]

Sir,—Allow me space in your Journal to request my surgical brethren to try the effect of the chloride of zinc paste in fistula in ano, having been successful in treating three cases by its use, which, otherwise, would have required the bistonry.

The ordinary paste, (chloride of zinc, water, and flour,) being entangled in a grooved probe, is passed up to the opening in the rectum. The point of a second probe or instrument is then placed in the groove, and passed just sufficiently high up, that, by its being retained in that position while the armed probe is withdrawn, the groove may be cleansed of the paste. This may be repeated every second or third day. I am, &c. E. Lacy.

Poole.

BITTER BEER.

[To the Editor of the Medical Times and Gazette.]

Sir,—You have already acquitted me of being "guilty of any kind of falsification," and express your pleasure that I came forward in a decided way to clear myself from even the suspicion of being a party to adulteration. With this, perhaps, I ought to rest satisfied; still, after the articles which had appeared on the alleged adulteration of pale ale, I considered it my duty to put myself in communication with perhaps the greatest authority of the day in matters connected with scientific research. Baron Liebig has long been interested in our peculiar system of brewing pale ales, and we have not unfrequently availed ourselves of his great knowledge in endeavouring to produce that which is the height of our ambition, a faultless pale ale.

The interval of distance has prevented my sooner sending to you Baron Liebig's opinions upon this question.

The subject of adulteration is, I hope, entirely set at rest. It will, however, be very gratifying to me if you will allow this eminent man to give the final blow, by inserting in your columns his letter to me, which I now enclose. I am, &c.

Henry Allsopp.

"The unguarded remark of a French chemist, that the strychnine imported into England is employed, in part, as a substitute for hops in the manufacture of beer, has lately spread alarm among the lovers of pale ale. Having been appealed to by you, to express my opinion on this subject, which appears to me to be, in a dietetic point of view, one of considerable public interest, I now offer the following brief statement:—

"About a quarter of a century ago, a brewer in Westphalia fell into the practice of adulterating his beer with nux vomica, from which it is well known that strychnine is obtained. The peculiar morbid symptoms, however, which resulted from the consumption of this adulterated beer, speedily led to the detection of the fraud. The effects produced by nux vomica and strychnine are so characteristic, that every medical man will readily detect their origin. The French novelist, Alexandre Dumas, has described them, though with more imagination than truth, in his romance of "Monte Christo." It is possible that the Westphalian case, which, from being made the subject of a criminal trial, obtained great notoriety,

has given rise to the assumption, that in England the strychnine imported is used for the purpose of mixing with beer. But nobody at all acquainted with the great breweries of that country, could seriously entertain the suspicion of an adulteration of beer with strychnine or any other deleterious substance. It is practically impossible, that any operation of a doubtful character could be carried out in these extensive establishments, on account of the large number of workmen employed in them. Any attempt on the part of the brewer, to impart qualities to his beer in an illicit manner, which are not to be obtained from malt or hops, would necessarily lead to his ruin; as he would be obliged to communicate his secret to too many persons, and to employ too many accomplices. The draymen themselves, as good connoisseurs in beer, would protest against any manipulation of a suspicious character. The case has even occurred, of an eminent brewer not venturing to make use of a method suggested to him, for the purpose of clearing his beer more effectually, because the addition of a new material to the wort might have induced a suspicion in the minds of his workmen, that it was an illicit proceeding, and this would have endangered the good reputation which his beer enjoyed. He stated to me, at the same time, that no improvement could be introduced into a brewery, the object of which was not perfectly evident to everybody.

"During a sojourn of several days at Burton-on-Trent, I had an opportunity of becoming intimately acquainted with the method pursued in the manufacture of pale ale. I convinced myself that the qualities of this excellent beverage depended mainly upon the care used in the selection of the best kinds of malt and hops, and upon the ingenuity exhibited in conducting the processes of mashing and fermenting. Our continental brewers have much to learn in these points to come up to the English brewers. I have no hesitation in saying, that England possesses the greatest adepts in malting. I know positively that the chief brewers of Munich, who, undoubtedly, produce the best beer in Germany, have gone through an apprenticeship in Burton. This may account for the predilection entertained by the general public, as well as by medical men, for these varieties of beer; for the instinct of humanity and experience appear to be as good guides in the choice of things that contribute to health and enjoyment as the profoundest philosophy.

"Professors Graham and Hofmann, in the excellent Report already addressed to you upon the alleged adulteration of the pale ale by strychnine, have indicated a very simple process for detecting the most minute quantity of strychnine contained in beer. I have satisfied myself of the great convenience and accuracy of their method, and have further assured myself, by an analysis of several specimens of pale ale obtained from London houses, supplied by your establishment, of the utter groundlessness of the imputation, that this beer was poisoned with strychnine. I am positive, and am supported in my views by the concordant analyses of all chemists who have occupied themselves with the examination of beer, that the poisoning of pale ale with strychnine has never occurred. I believe I may safely add, that it never will take place; for, although an ignorant brewer might be induced, from interested motives, to add nux vomica to his beer, the word strychnine so forcibly suggests one of the most virulent poisons, that whoever has heard anything about strychnine at all, is sure to be aware of this. By adulterating his beer with strychnine, the brewer would be knowingly committing a crime which, in the present state of science, must be followed by immediate detection and punishment.

"Mr. E. Merck, of Darmstadt, one of the most extensive strychnine manufacturers in Europe, informs me that this substance is peculiarly adapted to destroy vermin of all kinds. In many parts of Germany, it is the popular poison for rats and mice. This fact fully accounts for the large amount of the drug that has lately been introduced into commerce.

"The specimens of your pale ale sent to me, have afforded me another opportunity of confirming its valuable qualities. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust. "JUSTUS LIEBIG.

"Giessen, May 6, 1852."

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Comments have often been made on the new "dodge,"—shall I term it so,—of prolonging the debates at this Society for only one half hour after the usual time of closing; indeed, I have frequently heard medical men complain of the injury this habit does them in practice, as they never know now when the debate will be finished, as there are always some there who will talk for the sake of talking, and of seeing their names in print, tacked on to a larger or smaller amount of nonsense, as the case may be. But matters on Tuesday evening last transcended all others: a long and interesting paper by Dr. Kirkes was read; the lecture concluded at ten minutes to ten, and a short debate followed, which closed at ten minutes past. But the President was not satisfied, and he called upon some one to propose, as usual, that the debate be continued one half hour longer. No one answered the appeal, and he commenced dismissing his audience, when one of the fellows arose and began speaking to the question. At this, the President informed him he must first move the proposition just stated, and then, if carried, he might continue to chat about fibrin. This was done, and a seconder was found, but the motion was defeated, on a show of hands, by a majority of nearly two to one. Of this, however, the President took notice, nor would he have done so, but for a whisper from one of the Secretaries, startled at finding a large number of fellows on the point of leaving. After a little private conversation, when the greater part of those who were opposed to the continuance of the debate had left, the President called for another show of hands, and, I believe, carried the day.

Now, Sir, is this fair to the Fellows and visiters? They make their arrangements to stay till 10 p.m., and perhaps have appointments, or patients to see afterwards, or may have friends waiting for them at home, or may be desirous of rest after the toils of the day, but are called to stay out a discussion of another half hour, in order to give some gentleman an opportunity of having his speech reported in the medical journals. My life on't, if there were no reportings, we should not have any prolonged debates.

Yours faithfully, M.R.M.C.S.

THE CLAIMS OF HOMŒOPATHY TO THE CONSIDERATION OF ITS OPPONENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—In requesting the favour of the insertion in your periodical of the following remarks, I rely upon that spirit of fair, open, and honest inquiry which has always characterised it, and which has gained for it the admiration of so many members of my Profession.

When medical men are asked by the public, what they think of homœopathy, their universal reply is, "Humbug!" and this, too, when they have never taken the pains to study its principles or observe its practice. Does not this imply, that they are satisfied with the old system,—that it has, in their opinion, reached something like perfection, and is not, like other systems of old, susceptible of improvement? And yet, if we watch the bedside practice of these men, what is the result? Let any candid student, in quest of a rational system of physic, attend carefully to the practice of our great hospital physicians, and he cannot fail to be convinced, by their various and opposite methods of treating the same diseases, that they are inwardly conscious of the defective state of therapeutics, and of a sad want in this respect of something like a fixed, guiding principle. In proof of this, I might adduce many cases; but let it suffice, that I have myself seen cases of pleurisy, pneumonia, and acute rheumatism, under the care of the most eminent physicians in London, treated by lemon-juice, which cases, by other eminent physicians, or by themselves at other times, would be treated by bleeding, cupping, calomel, opium, and tartar emetic. I have also seen all the cases in a clinical ward indiscriminately treated for weeks by a quack medicine called "Warburg's Tincture," the composition and properties of which were totally unknown to those prescribing it. I say, then, that, when we see the leading men in our Profession deserting the old and more generally received methods of treatment, for others which are new, or opposite, or unknown, it is fair to conclude, that they are either guilty of wanton cruelty to their patients, or, as I believe, that they are conscious of the defects of the present system of therapeutics, and anxious to discover a better. Adopting, then, the latter supposition, I shall proceed to show, that they are bound to consider the system of homœopathy, and put it to the test of practice.

There are but two kinds of truths,—(*a*) those which may be discovered by *à priori* reasoning, which are implied in what we already know, are elicited by reasoning alone, and not by observation or testimony; and (*b*) those which are commonly called "matters of fact," which, before they were discovered, were absolutely unknown, and not implied by anything we previously knew; these we could never possibly arrive at by the internal workings of our own minds;

we gain them by observation, experiment, and testimony; and if the observations and experiments have been carefully conducted, and the testimony respectable, we assent to the truths. To the former class belong the truths of mathematics and metaphysics, which a man may reason out in his arm-chair. To the latter belong most of the truths in medicine, which can only be arrived at by experience and observation. These two classes of truths are well illustrated in the well-known and often-quoted words of Sir J. Herschel:—"A clever man, shut up alone, and allowed unlimited time, might reason out for himself all the truths of mathematics, by proceeding from those simple notions of space and number of which he cannot divest himself without ceasing to think; but he would never tell, by any effort of reasoning, what would become of a lump of sugar, if immersed in water, or what impression would be produced on his eye by mixing the colours yellow and blue—results which can be learnt only by experience." Now, it requires no argument to prove, that homœopathy belongs to the class which we call "matters of fact." No *à priori* reasoning, therefore, can possibly decide whether or not globules produce the effects attributed to them. A long series of experiments, carefully conducted by men of intelligence and good character, alone can decide this point; in short, in order to pronounce upon homœopathy, we must put it into practice. I am consequently at a loss to conceive what has become of the philosophy, the logic, and even the common honesty, of those members of our Profession, who boldly pronounce upon a "matter of fact" without consenting to fulfil those conditions which are essential to the settlement of all such questions. In this particular, the public are their superiors in intelligence. They well know, and feel, that there is no force or conclusiveness in the reasonings of a man upon a "matter of fact." Their plain question is, "Have you tried it?" or "Have you seen it tried?" and, if the reply is, "No," then all their subsequent arguments have not the slightest weight. To all this it may be objected, that, upon precisely the same grounds, medical men are bound to try "Holloway's Pills," or, indeed, any and every other quack remedy. To this I would reply, that, in the case of "Holloway's Pills," the conditions, (viz., respectable testimony and carefully conducted experiments,) essential to the settlement of questions of "matter of fact," are wanting; whereas, in the case of homœopathy, we see a large hospital devoted to its practice, supported by some of the most logical, intelligent, and honest among the public, and superintended by medical men of eminence, intelligence, and respectability. We have, then, in homœopathy, a question of a "matter of fact," with all the conditions necessary for its determination; and I say fearlessly, that the physician who refuses to apply himself to the subject, and put the system into practice, or watch the practice of others, is not a worthy member of his Profession, because he omits a duty which he owes to himself, to the public, and to his Maker!

I have been, and am still, strongly opposed to, and prejudiced against, homœopathy; but I see clearly, that I committed a great mistake in endeavouring to settle the matter off-hand, by *à priori* reasoning; and I would now approach the subject in the true spirit of Lord Bacon, who says: "All idols must be abjured and renounced, with firm and solemn resolution, and the understanding must be completely freed and cleared of them, so that the access to the kingdom of man, which is founded on the sciences, may resemble that to the kingdom of heaven, where no admission is conceded, except to children."

Trusting you will oblige me by an early insertion of these remarks, I enclose my card, and remain, &c.

London. ALLOPATH.

[We publish this letter because it has been sent to us by a regular practitioner; but we do so with some scruple, as it is evident that the writer is not conversant with the subject. No one ever pretended that homœopathy is to be refuted by *à priori* reasoning; it has been refuted by direct experiment, as in the Paris hospitals many years ago, and by analysis of the dogmas on which it is based. Our correspondent appears to us peculiarly unfortunate in his illustration of the different kinds of method of investigation. Mathematics and metaphysics are, equally with medicine, founded on experience and experiment.

As to ordinary therapeutics, no one ever pretended that the subject is perfect. Medicine, like all sciences, is to be advanced by experiment and observation. We treat rheumatism now with a certain degree of success; there is no reason why we should not endeavour to find out a better method.

If medical men are so little conversant as is our correspondent with the true foundation of therapeutics, and with the true method of advancing the art of healing, we do not wonder that they find themselves beaten in argument by the homœopaths. "Allopath" is even apparently ignorant of the derivation of the signature he adopts; otherwise, we think, so close a reasoner would scarcely have employed it.—ED. *Medical Times and Gazette.*]

NEW CHARTER OF THE COLLEGE OF PHYSICIANS.

[To the Editor of the Medical Times and Gazette.]

SIR,—As a draft of a new Charter of the College of Physicians is before the Profession, I take the liberty of asking you, whether "such testimonials of character and professional qualification as shall be satisfactory to the said Censors," have any reference whatever to professional character, as involved in a total departure from the customary fees of physicians, fellows, and members of the College?

Will the M.D. be admitted a member who accepts a single fee of 5s., whose visits are made at the paltry rate of 2s. 6d., or it may be for 2s. when the florin comes into use, and journeys, and even journeys in consultation, as I have heard, at the charge of 1s. per mile? There can be no honourable competition, much less friendly co-operation, where such professional delinquency is found.

If a bond of union is wanting, made up, not of written rules and regulations, but of unwritten, but well-understood and honourably-practised observances, as a portion of the medical ethics by which our Profession should be governed, there is very little hope of advantageous union for the moral, material, or social welfare of physicians.

The lawyer's charges are regulated by law; the barrister's fees by custom, which, in the absence of law, binds an honourable profession; among clergymen there is a customary remuneration.

Is the cutting system of the tradesman to be forced upon the physician? The physician whose privilege it has been to do much gratuitous service, taking from those only who can afford a fee in gold, but an *aurea mediocritas*, as the Property and Income-tax Commissioners well know. I am, &c.

M.D. EDIN.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

JOHN BISHOP, ESQ., F.R.S., President, in the Chair.

CASE OF GANGRENE OF THE LUNG.

Dr. Halley read an extract from a letter, giving an account of an interesting case of gangrene of the left lung, which occurred at the Merchant Seamen's Hospital at Hong-Kong, under the care of Dr. W. A. Harland, of that Hospital:—"An American sailor was brought to the hospital in such a condition as almost to preclude all hope of his surviving beyond a few days. On the second day after his admission, he fell out of bed, and on being raised up again, he complained of severe pain under the left mamma. Dr. Harland immediately examined the part, and found a swelling of considerable size, with distinct fluctuation. With some hesitation, he made a small incision, and finding an escape of pus only, he enlarged the opening to about an inch and a half in length, when upwards of half a pint of extremely fetid pus, with small shreds of gangrened lung, were evacuated, the discharge being suddenly stopped by a mass of the dead lung itself protruding through the orifice. By gentle traction with the forceps, he was enabled to withdraw this to the extent of nearly two inches; but finding it not yield any further, and afraid of hæmorrhage if he cut it, he applied a poultice, which was renewed every three or four hours, and at each dressing pulled out the lung a little more as the opening increased in size by ulcerative absorption. On the third day after the incision was made, the protruding mass became so troublesome and offensive, besides exhibiting some appearance of spontaneous separation, that Dr. Harland removed it with the knife. No hæmorrhage occurred, and the opening appeared to be filled up by the pericardium, (as by a valve,) which gradually became thickened, and adherent all round to the parietes of the chest. The detached piece of lung would scarcely go into a pint measure, and weighed

nearly a pound. The man rapidly recovered, and about three months afterwards shipped again as a seaman, in a vessel bound to New York." Dr. Harland subsequently writes:—"Last month (Dec. 1851), I was agreeably surprised by a visit from my old patient, who came to show me that he was alive and quite strong and hearty again. It appears, that, in consequence of the ulceration having exposed a part of one rib, some discharge continued to ooze from the wound for some months after he left me, on which account he went into one of the hospitals on his arrival in New York. Under medical treatment for a short time, the wound soon healed, and his case excited considerable interest, almost all the principal medical men there having visited and examined him. From New York he went to sea again, and then to the mines in California, where he worked as a gold digger for above a year, and at last he returned to Hong-Kong, where he arrived last month. He told me he could work as well as ever, and had never been troubled with cough since he left me; the only difference he could perceive was, that he thought he was rather shorter breathed than before, if he had to exert himself strongly for any length of time. A marked difference, too, is at once perceptible in the relative dimensions of the two sides of the chest. He went back to California a few days ago (Jan. 29, 1852)." Dr. Halley regretted, that more particulars were not added in regard to the subsequent physical and auscultatory signs, but hoped, at a future time, to lay them before the Society; at the same time, he thought the case so remarkable and unique as to be well worthy their attention, even in its present form.

Dr. Cotton brought under the notice of the fellows

A NEW MODE OF APPLYING TOPICAL MEDICATION TO THE LARYNX.

After adverting to the subject as recently discussed by the Society, and repeating his conviction, that the ordinary practice of passing a sponge into the larynx was not only in the majority of cases practicable, but also unproductive of injury; he had, nevertheless, felt that it would be desirable, should it prove equally beneficial to the patient, to apply the solution of nitrate of silver without actually introducing the sponge. He believed that there were many practitioners who, whilst admitting the great probability of local applications proving useful in certain laryngeal diseases, were unwilling to employ them, from a fear of the operation. The introduction of the instrument was also frequently alarming to the patients themselves; and there was the chance, although a slight one, of the sponge being pulled off by spasm of the larynx. To remedy such inconveniences, Dr. Cotton had requested Mr. Coxeter to make the simple instrument he now exhibited, and which he had successfully employed in a number of cases at the Hospital for Consumption. It consisted of a pair of curved forceps with flattened blades, to one of which was fixed in a peculiar manner a small piece of sponge, intended to contain the solution. The tongue being depressed and drawn forwards, as in the other method, the forceps are introduced into the mouth, and, at the proper moment, the contents of the sponge squeezed into the larynx. It might be supposed, that the solution would sometimes fall into the trachea without touching the mucous surface of the larynx; but this could seldom, if ever, happen, for a small portion is almost sure to come in contact with the latter, and the cough and spasm, which always immediately ensue, must effectually scatter the application. Several patients, upon whom the other instrument had been previously used, had greatly preferred the employment of the forceps. Dr. Cotton hoped to bring this subject more fully before the Society at a future period; in the meantime he would commend its consideration to the fellows.

Dr. Camps inquired the strength of the solution used by Dr. Cotton. He understood him to say, a saturated solution; was it so, and did he use it in all cases of phthisis?

Dr. Payne Cotton replied, that if he used the phrase "saturated solution," it was an error; he should have said, the sponge saturated with the solution. He did not know, in fact, what the strength of a saturated solution would be. He had, at first, employed a solution of the strength of ʒss. to ʒi. of distilled water, but this he found caused too much irritation; and he now employed a solution, varying in strength according to the circumstances, from gr. v. to ʒj. to the ʒi. of the solvent. He did not use it in all cases of phthisis; in very advanced cases the chances of relief being afforded by it were so slight, that he did not think it right to subject the sufferer to the annoyance of the application; but in early instances of laryngeal phthisis, and in cases of laryngeal disease, independent of phthisis, and also in the aphonia to which hawkers are peculiarly subject, its application was very beneficial, and such as to warrant its employment. He should, with the permission of the Society, bring the subject before them some time during the next session.

WHAT IS METASTASIS?

Mr. Pilcher stated, that his object in selecting this subject for his address to the Society was to afford an opportunity for the fellows to determine whether such a condition as that generally understood by metastasis really existed; and if so, to more accurately define and limit its meaning,—the more particularly as, upon the term being used during a former discussion, a distinguished member of the Society frankly declared he did not know what metastasis meant. The term—from *μέτασταω*, "I transfer"—was employed by the ancient physicians to designate the transposition of a disease, its nature remaining the same, from one organ to another. They designated, under the name of diadosis—*διαδοχή*—the transformation of a disease into an affection of a different nature, and occupying another organ. Thus, when hæmoptysis replaced a suppressed hæmorrhoidal hæmorrhage, it constituted metastasis; when a disease of the skin terminated in chronic inflammation of the chest, it formed diadosis. The moderns have united these two orders of phenomena under the single term metastasis, which expresses indiscriminately a change, whether in the seat only, or at the same time both in the seat and in the character of the disease. Does metastasis occur independently of fixed rules and general principles? Is it not, in fact, an aggravation of the general laws of disease, which is for the most part secondary, or even ternary, and not infrequently quaternary, and when fatal, is generally consecutive of a preceding affection; of which abundant examples are presented in internal inflammations, and in fevers, both idiopathic and symptomatic, of which Mr. Pilcher mentioned several instances. The difference between symptomatic or sympathetic disease and metastasis is very slight, if it exist. Mr. Travers, in his work on Constitutional Irritation, appears to consider them as identical. There are three modes, certainly, in which symptomatic or secondary diseases arise—first, continuity or contiguity of structure; second, association by means of the nervous system; third, similarity of function; and perhaps fourth, unity of an apparatus of dissimilar organs to produce one function; and fifth, identity of structure and function, though in health producing a different result, and the organs situated at a distance from each other. Of each of these causes of secondary disease—or of metastasis, as it is sometimes called—several examples were given; among others, of the first, erysipelas was noticed, extending to the structures beneath, to the fasciæ and the muscles, through the scalp to the pericranium and bone, and on to the cerebral membranes and brain; also from the face along the entire alimentary canal; or in the reverse direction. Of the second, the known sympathies between the stomach and brain, between the kidneys and the thighs; between the hip and the knee, the liver and the shoulder or neck; between the intestines and the spinal marrow, through the medium of the great sympathetic; and probably, by these means, between every part of the animal economy. Of the third, similarity in function, perhaps the most interesting of sympathies, examples were noticed in the skin and lungs, the skin and the kidney, the skin and mucous membranes, the lungs and the liver,—the last so well seen in the effects of temperature upon the two organs, the cold climate requiring an inordinate action of the lungs to furnish the requisite caloric, and thus necessarily disengaging the carbon from the system; the more elevated temperature demanding a less amount of respiratory function, calls upon the liver to secrete a proportionally larger quantity of carbon; hence the greater or less degree of action in the two organs augments or diminishes the predisposition to disease. Of the probable fourth mode of sympathy in disease, the examples of the digestive apparatus, of the circulatory, and of the urinary and generative, were afforded. It was certain, also, that the other three kinds of *modus operandi* exerted their full influences in producing consecutive affections, as stricture of the urethra, destroying, through disease in the bladder, the ureters, or the kidneys; yet disease of the kidney will irritate the urethra, without producing apparent affection of the ureters, or the bladder, and the reverse; likewise affections of the stomach excite disease in either extremity of the digestive canal, leaving the intermediate portions healthy, as far as symptoms allow the recognition; affections of the liver being followed by disease of the spleen, and the reverse. Of the fifth mode, examples may be adduced in the association existing between the voluntary muscles and the heart, the voluntary muscles and the diaphragm; the former indicated in muscular rheumatism affecting the heart; the latter seen in the spasm of cholera alternating between the external muscles and the diaphragm. It is difficult to account satisfactorily for this metastasis of disease from the voluntary to the involuntary muscles upon known physiological principles; yet it must be similar to that from one fibrous structure to another, which is so constantly witnessed. The difference in function between these two sets of muscles is

proved, by the excito-motory doctrine, not to be so great as formerly imagined, since all muscles possess an involuntary action, and the different arrangement of their fibres may be insufficient to lessen their general predisposition to disorder; these facts being allowed, it may be readily comprehended that the inordinate action of the great engine of circulation should, during the fever of rheumatism, place it in a condition peculiarly liable to be secondarily affected by the existing general disease. Metastasis is not unfrequently confounded with coincidences in disease; different affections occurring at the same time, either from the same or from different causes; and likewise proceeding from the same cause, though developed at a distant period of time; examples of which are frequently seen in instances of mechanical accidents, and in affections arising from poisons, and particularly from poisoned or malarious atmospheres. In many such cases, diseases of different organs may have no other relation than that of similarity of predisposition and of cause. Counter-irritation affords one of the best examples of the so-called metastasis, though, being usually excited artificially, it is denominated a devitant; hence exists the marked difference in the two conditions. A "materies peccans" is supposed to account for the transference of disease; and, in many instances, a morbid state of the blood gives rise to affections consecutively occurring in distant organs or tissues; but so far from being cases of metastasis, these blood diseases are continuations of the same affection, locally developed here and there, and at various times, as predispositions and existing circumstances may determine. At present our knowledge of this "materies peccans" is too vague and speculative to justify the foundation of a pathological doctrine. Among the examples of metastasis were mentioned: first, that of arthritic rheumatism to the heart or to the brain, accounted for by a like structure (the fibrous) in each being affected, and the then existing peculiar predisposition in the relative organ to be influenced by the general disease. It is also most frequently an addition to the inflammation of the joint or joints, and not a substitution, the original local affection continuing its course. Preparations illustrating this condition were shown, in which the inflammation of the knees suddenly subsiding, the pericardium became acutely inflamed, and proved rapidly fatal. Gout passing from one joint to another, and from the joints to the viscera, obeys the same laws as rheumatism, though appearing most capricious in its relations and in the rapidity of its transposition; more frequently than otherwise occurring as the consequence of a local cause. A gentleman had gout in the right great toe, with a red spot on its side, no other symptom existing. Upon leaving a warm bath, he struck the left great toe; instantly the gout left the right, and appeared with a similar spot in the left toe. A martyr to the gout was persuaded against his judgment to take a glass of champagne; before he had half emptied the glass the gout appeared in his foot. Gonorrhœa producing epididymitis is merely an extension of inflammation along the vas deferens; the occasional non-appearance of disease in the spermatic cord is no proof of its non-existence. Gonorrhœal ophthalmia can generally be traced to direct inoculation, and most probably always so arises. Gonorrhœal rheumatism and gonorrhœal lepra are most probably blood diseases. The secondary and ternary diseases of syphilis are certainly the results of a poisoned condition of the blood. The metastasis of mumps to the testicles, and to the mammæ in girls, possess a considerable apparent peculiarity, both in their great frequency, and in the dissimilarity of the affected organs in their structure and functions. The idea of this peculiarity may be lessened, though it may not be accounted for, by the fact, that the metastasis usually occurs when the testicle or breast is especially predisposed to inflammation, it then being in a state of almost, but not quite, complete development; besides which, there appears reason to believe that an association exists between the development of the salivary glands and that of the generative organs, as well as between the latter and the organs of voice,—an interesting circumstance occasionally exemplified in man, and constantly in the varied development of these glands in the entire and castrated neat animals. Purulent deposits, or secondary suppuration in distant tissues, cannot be accounted for on the supposition of absorption only, either through the medium of the lymphatics or of the veins, or of both, though it is not to be denied that pus-globules are occasionally received into the blood. Dr. Froriep is of opinion, "that the materials going through the capillaries to the blood are in a state of solution, and do not contain globules, for the porosity of the membrane is not sufficient to permit the passage of globules of pus, so that the appearance of such globules must be co-existent with the effusion of matter. Hence it is incorrect to suppose that a direct discharge of globules of pus takes place into the sac of the pleura, the peritonæum, or the cavity of the arachnoid, as it is said in purulent metastasis; and it is equally erroneous to imagine that, where pus ceases to be secreted from the surface of a sore, it has been transported in the current of the circulation, and deposited in some internal organ where inflammation is going on." It must, however, be conceded, that these "depôts of pus" are the result of a morbid state of the blood, derived from the original abscess or suppuration, and the localization of the new inflammation and its consequences is determined by peculiar local conditions. In most cases, and perhaps in all, the metastatic affection occurs in similar structures, though it may be in dissimilar organs; nor does it necessarily terminate in suppuration or purulent deposit, though originating from that source. A young man was inoculated with glanders from a dead horse; suppuration of the joints occurred, first in one, then in another; the external inflammation suddenly subsided, and he rapidly died from suppuration of the peritoneum. A post-boy had an abscess in the axilla; in a moment he became raving mad; a drachm of laudanum was administered, the abscess was opened, and he at once recovered. A man with a cavity in the lung suddenly became deranged; the disease of the lung was arrested; he was committed to prison in consequence of his violent actions, and thence sent to a lunatic asylum; when the mind was restored, the lung renewed its diseased action, and quickly proved fatal. A boy, 10 years old, struck his left leg on the 22nd of January, but did not much complain till the 25th, when he went to bed. On the 27th, he was admitted into St. Mary's Hospital, complaining of great pain in his leg, which was swollen, and very tender. Upon examination, he was found to labour under pericarditis and pleurisy, from which he died on the following morning. The *post-mortem* examination showed periosteal abscesses of the left leg and thigh; recent pericardial and pleuritic adhesions; purulent deposits in the lungs, heart, and kidneys, and thickening of the popliteal vein. The metastasis of disease from the skin to the lungs, and almost invariably to the mucous membrane, however it may afterwards extend to the other tissues, is too common to need cases of illustration, and unhappily too frequently fatal in acute affections, and especially in the exanthemata. Many of these cases are attributable to evident extension along the surface of the allied membranes; others to the arrest of the cutaneous function, exciting that of the respiratory. It should never be forgotten, that the external and internal dermoid structures are mere modifications of each other. Similar observations are even more applicable to the association in disease of the skin and intestinal mucous membrane, in which metastasis, however, the affections are more frequently found to be chronic. How constantly it was customary to rank uterine phlebitis, with all its distressing consequences, under the head of metastasis, whereas it is now completely proved to be an extension of disease along the veins, not infrequently attended by the supposed absorption of pus. One of the most remarkable examples of so-called metastasis is seen in the effects of a slight external injury, terminating in delirium, and even producing a fatal shock. From the foregoing facts and remarks, Mr. Pilcher considered it a fair and reasonable deduction, that though the term "metastasis" may be very conveniently and usefully employed in its limited sense, such a condition as it is generally meant to imply, does not really exist; that the very large majority of these cases are to be accounted for upon the general and recognised principles of physiology and pathology; and that, in the occasional instances in which such known laws and the presented facts cannot be reconciled, it is due to our own imperfect acquaintance with those laws and principles, and not to any vague and capricious action of Nature.

Some desultory conversation followed, but nothing was elicited rendering a report necessary.

MEDICAL NEWS.

Military Appointments.—Gold Coast Corps, Staff-surgeon of the 2nd class, Thomas Kehoe, M.D., to be Surgeon. Hospital Staff Assistant-surgeon, William Donneland Marchant, to be Staff-surgeon of the second class, vice Dolce, deceased. Assistant-Surgeon, James Davys, from the Gold Coast Corps, to be Assistant Staff-surgeon, vice Marchant, promoted.

Naval Appointments.—Surgeon Archibald J. Little (1845), to the Basilisk, steam-sloop, at Portsmouth; Assistant-Surgeon Daniel W. Stephens, M.D. (1848), from the Highflyer, steam-sloop, to the Basilisk. Assistant-Surgeons Daniel Finucane, M.D., (1851), confirmed to the Fantome, 12, sloop, on the Australian station; F. G. Barr, (1852), to the Fisgard, flag-ship, at Woolwich; Henry Williams, (1852), to the Vulcan, steam troop-ship, at Portsmouth; George More (1848), from the Impregnable,

flag-ship, at Devonport, to the Nereus, 42, store depôt at Valparaiso; E. R. Prouse, (acting), to the Portland, 50, on the Pacific station.

Obituary.—On the 21st ult., John Lewis, Esq., Surgeon to the Forces, half-pay officer in charge of the medical stores, Fort Pitt, Chatham, in the 78th year of his age. Mr. Lewis entered the service fifty-seven years ago, and was engaged in the active discharge of his duties until a few days before his death, —by which event the public has lost a most zealous and respected servant.

Testimonial to James Paget, Esq., F.R.S.—On Monday, 31st of May, a handsome cabinet of surgical instruments, the gift of more than seventy gentlemen, was presented to Mr. Paget, in the Collegiate Hall of St. Bartholomew's, to testify, on the occasion of his retirement from the wardenship of the College, their gratitude for his services, while they were residents in that establishment, and their admiration for the uniform ability and kindness with which he discharged the duties of his office. The following inscription, engraved in ivory, had been placed on the front of the cabinet:—"Presented to James Paget, F.R.S., in testimony of high regard and esteem by students who were resident in the College during the period of his wardenship. May, 1852."

Dr. Horatio Nelson Chipman has been appointed a member of the Legislative Council of the Bahama Islands.

Medical Benevolent College.—At a meeting of the Council, held at the Hanover-square Rooms on the 1st inst., the President (Earl Manvers) in the chair, the Earl of Carlisle was unanimously elected a Vice-President of the College. A vote of thanks was accorded to the Bishop of Ripon for having, on the 23rd ult., preached in aid of the funds, and also to the Rev. George Evezard for having kindly granted the use of his pulpit on that occasion. The Treasurer's Report was highly satisfactory, upwards of 1000*l.* having been subscribed since the last ordinary meeting of the Council.

The Militia Bill.—In the House of Commons, on the 27th inst., the following Petitions were presented on the subject of the Militia Bill:—By Mr. Thornely, for exemption of the University of London and Colleges connected therewith from the provisions of the Militia Bill; from Neesby Colleges, Sheffield and Taunton, St. Thomas's Hospital, Borough; lecturers of Westminster Hospital, Hull, and East Riding Schools of Medicine; physicians and surgeons of Northampton; Leeds School of Medicine; Queen's College and Manchester New College; two students of University College; professors of University College; Council of Huddersfield College; the Royal School of Medicine, Manchester; and Committee of Graduates, Manchester College, — to the same effect.

Liability of Hospitals to Rating. — In the Court of Exchequer, on Saturday last, in the case—the Governors of the Bedford Infirmary *v.* the Commissioners of the Bedford Improvements, Mr. Worlledge, on behalf of the Commissioners, contended, that the hospital did fall within the Act which rendered liable all halls, chapels, schools, almshouses, and all other public buildings, and embraced existing and all future erections. As to the mode of rating, he contended, that the building in question was rateable under the Act for the whole length of its frontage along a pathway, as well as that along a turnpike. Mr. Pearse, for the hospital authorities, submitted, that the Act should be limited to buildings *ejusdem generis*, and that a hospital did not come within that rule. As to the mode of rating, he denied the liability to be rated for the front along the footpath, and confined the liability along the turnpike to the width of the entrance-gates, the building in question standing within a large enclosed area. The Court was of opinion, that, on both points, their judgment ought to be in favour of the Commissioners; but, as they had rated the hospital for a part of its front along private property, as well as the turnpike and footpath, in respect of which there was certainly no liability, the judgment ought to be without costs.

Metropolitan Free Hospital.—Number of patients relieved during month of May. New patients, medical cases, 1169; surgical, 406. Total, 1575. Numbers in general attendance during the month, 4143.

Blenheim-Street Free Dispensary.—New patients during month of May. Medical, 404; surgical, 150. Total, 554. In general attendance during May, 2658.

Pathological Society of London. — At the last meeting of the Society for the present session, Cæsar Hawkins, Esq., President, in the chair, after the scientific business of the evening had been concluded, the President, in proroguing the meeting, congratulated the members on the success that had attended their efforts, and on the large number and the interesting nature of the pathological specimens that had been brought under their observation. He remarked, that a grand criterion of their success was the number of new members (41) during the session, being a great increase upon any previous year. He concluded by making the following statement as to the condition of their finances for 1851-52:—164 annual subscriptions, 172*l.* 4s.; 2 non-resident, 4*l.* 4s.; 37 entrance fees, 38*l.* 17s.; 2 arrears, 2*l.* 2s.; 2 life payments, 21*l.*; 1 payment for Transactions, 1*l.* 1s.: total receipts, 239*l.* 8s.

Mr. Sproull, Assistant-Surgeon Royal Navy, has been severely wounded in the engagement with the Burmese for the possession of Rangoon, and Dr. Davidson, of the 43rd regiment, has been killed in action with the Caffres. It is, nevertheless, said, that medical men, as non-combatants, incur no danger in actual warfare!

The Burmese War.—The following is the testimony borne by Rear-Admiral Austen to the conduct of our medical brethren in the Burmese war. He says: "I was an eye-witness to the indefatigable exertions of Dr. Minter, surgeon of the Fox, at the hospital on shore, and on board the Tubal Cain. Dr. Montgomery, superintending surgeon, expressed himself to me as being under the greatest obligations to him for his assistance. In addition to the duties performed by Dr. Minter at the hospital, he had those of his own ship to attend to, where the cholera had broken out with some virulence. Mr. Seccombe, assistant-surgeon of the Hermes, was also employed at the hospital on shore.

Mortality Notabilia.—The return for the week that ended May 29th is a proof of considerable improvement in the public health. The deaths registered in the second week of May were 1070, in the following week they declined to 943, and last week they fell to 883. In the ten weeks corresponding to last week of the years 1842-51 the average was 877, which, if raised in proportion to the increase of population, will be 965. The mortality of last week is therefore less than the calculated amount by 82. In comparing the results of the last two weeks it will be seen, that there is a decrease in zymotic diseases from 228 in the preceding return to 205 in the present, in diseases of the respiratory organs from 131 to 115, in tubercular diseases (including phthisis) from 189 to 177, in diseases of the nervous system from 120 to 104, and in those of the digestive organs from 59 to 50. Taking particular heads in the zymotic class, the cases in which hooping-cough was fatal declined from 42 in the previous week to 31 in the last, those of croup from 10 to 4, of typhus, etc., from 41 to 31. On the other hand, the mortality caused by small-pox, measles, scarlatina, diarrhœa, and erysipelas does not vary, or only to a trifling extent, in the two returns.

DEATHS *in the Metropolis for the week ending Saturday, May* 29, 1852.

TO CORRESPONDENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a case of dislocation of the sternal end of the clavicle backwards, I mentioned, that it remained unexplained, why, in that particular instance, dislocation took place rather than fracture. Moreover, I drew especial attention to the manner in which the accident happened, as it was extremely unusual. The dislocation has been produced (in all the cases I can refer to) either by a force thrusting the shoulder forwards, or by violence applied at, and thrusting backwards the inner end of the clavicle; whereas, in the present case, it was produced by a force applied at the middle of the bone. A "St. George's Student" has attempted to explain why, in this instance, dislocation took place rather than fracture (the common result of similar violence) by citing experiments proving the strength and elasticity of the clavicle. That this explanation is not the correct one we know by the fact, that fracture of the clavicle is one of the most common accidents, and that dislocation of the sternal end of the bone backwards is so rare as to be a surgical curiosity. Your Correspondent has also offered an explanation, that the horse's hoof (? shoe) might have covered the whole length of the bone, and have caused dislocation; but if he refers to the narrative of the case he will find that there is no evidence to prove that violence was applied to any other part but the middle of the bone.

I am, &c.

Middlesex Hospital. S. W. SIBLEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Allow me to draw your attention, and, through the medium of your Journal, that of the Graduates' Committee of the University of London, to a point which I had expected to have seen noticed before.

In the proposed new Charter of the College of Physicians, it is provided, that all Doctors of Medicine, &c., practising as Physicians at the date of the Charter, shall be admitted as Licentiates of the College without examination; but no mention is made of Bachelors of Medicine. Is it, then, to follow, that all holding that degree from the University of London, and many of whom are at present practising as physicians, are to submit to an examination before they can be placed in a legal position; whilst a promiscuous crowd, holding a nominally higher degree, but who have never been subjected to half the test of competency which the former have, shall at once be admitted?

I hope, for the credit's sake of the framers of the Charter, that this omission has not been intentional. I am, &c.

Trinity-square, Southwark. JUSTITIA.

Mr. Benson is strongly recommended to emigrate, rather than, under his circumstances, to enter the Profession. He could possibly get a free passage out; and his funds, too small for this country, would be amply sufficient to found his fortunes in Australia.

A Surgeon.—Mr. Paget's valuable lectures will be published—partly in our Journal, and partly as a separate work.

Horace and Bistoury must apply at the Emigration Office.

Studens.—A Surgeon's diploma; published works and strong recommendations. Residence is not required.

Dr. Mackenzie's Case of "Farcy" is in the printer's hands.

J. T., Edinburgh, must authenticate his letter before publication.

Dr. Holdsworth.—Only by application at the College.

[To the Editor of the Medical Times and Gazette.]

SIR,—May I trouble you to inform me, in your Notices to Correspondents, whether, if a patient engages me to attend her in her confinement for a certain fee, and then sends for another medical man whose charge is less, without giving me any intimation of the same, I have any legal claim upon her for the said fee. I am, &c. A SUBSCRIBER.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the heading of my paper on Entropium, in the "Medical Times and Gazette" for the 22nd ult., there was a mistake in my titles, it having been implied, by an omission, that I am Surgeon to St. Mary's Hospital. I beg to correct the error. I am, &c.

H. HAYNES WALTON,
Surgeon to the Central London Ophthalmic Hospital; and
Assistant-Surgeon to St. Mary's Hospital.

55, Grosvenor-street.

Mr. Mitford's letter is transmitted to Mr. Yearsley, who will probably reply to it.

Inquisitor.—It is *possible* to acquire a knowledge of the practical use of the microscope by hard work, much reading, and great disappointments, without attending any *viva voce* instruction upon the subject. "Inquisitor" will, we think, have all his requirements satisfied by the careful study of a series of lectures commencing early in the next Volume of the "Medical Times and Gazette," by John Boon Hayes, Esq., Professor of Physiology in Sydenham College, Birmingham.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last Number, Dr. Graves has noticed a mistake in reference to his own experience of the quinine treatment of continued fever, alluded to in the "Edinburgh Journal of Medicine," and which will, doubtless, have been a typographical error. As the following extract from Dr. Graves' letter on this subject was published by me in the May Number of the "London Journal of Medicine," Dr. Graves subsequently referred me, for the particulars of the cases, to Dr. Richard Kelly, Physician to the Drogheda Fever Hospital, whose letter was published at the same time, and which I also now subjoin. I am, &c.

ROBERT DUNDAS.

"Merrion-square, 22nd March, 1852.

"....At my desire, your quinine treatment of typhus has been tried in one of our hospitals, and with success. When I receive the notes of the cases, I shall not fail to let you know.

"To Dr. Dundas." "ROBERT S. GRAVES.

"Drogheda, 3rd April, 1852.

"With regard to your original treatment of typhus fever, I must acknowledge myself a convert, as I have treated eight cases of the most severe description with the happiest results.

"I shall, however, enter into details of one of the most severe cases under my care.

"A poor farmer, named Pentony, aged 55, was admitted into hospital 16th February; had been ten days previously ill. The pulse was 120; the tongue dry and brown; he had constant muttering delirium. The respirations were forty; the skin covered with maculæ; the temperature 90°. He had involuntary discharges, and subsultus tendinum.

"In two days after the administration of quinine (according to your directions) he was convalescent, and left the hospital in excellent health ten days after.

"In my opinion, such a happy result could not have been procured by any other treatment that I am aware of.

"In three of the fore-mentioned cases, four members of the families died in the houses from which my patients were removed; and, in one case, the patient had been afflicted with chronic bronchitis for years, but it did not militate against the treatment.

"Trusting that such an invaluable improvement may be adopted by the members of the Profession, and that my humble testimony may be of service in the trial of it. I remain, &c. "R. KELLY.

"To Dr. Dundas, Liverpool."

[To the Editor of the Medical Times and Gazette.]

SIR,—For twenty years I have been reading in the medical journals about reform, and colleges, and charters,—about Poor-law conventions, unrequited labour and professional non-prosperity; and for twenty years more (if I live so long) I shall continue to read the same story, and be of the same mind as I am now, viz., that the common-sense commercial maxim of supply and demand is the cause of the poverty of the Profession, and of the adoption of so much humhugging to gain a scanty livelihood. Your recommendation to the strong hacks to cut for the diggings, and to leave room at home for the rest, is of no use, so long as the colleges, universities, and faculties glut the market with their *protégés*. Supply and demand is as true in physic as in sugar; and what care the competing colleges about their men after the licence-money is paid?

The breed of doctors, surgeons, chemists, druggists, quacks, is each increasing, and now and then judiciously crossed, with much advantage to the person, and none to the Profession. This state of things is going on, and will go on, and has gone so far, as for you to recommend the diggings. Where I am, while the population is doubled, the medical men and druggists have increased five-fold. The adjoining district is the same. The colleges, to whom we paid our money, have caused this state of things; and what do they care? It would pay the Profession very well if most of the examiners were pensioned off or compensated. If there were only three licensing bodies; and, by raising the qualifications and fee, stop the glut of doctors. This glut lowers them personally and professionally; and so it will where the supply is above the demand. Free trade in physic would be all very well if the people could be a good judge of quality; but as they are not, their medicine is adulterated with ignorance and successful knavery; and if ignorance and successful knavery pay better than an honourable practice of the science of medicine—*ubi bene, ibi patria*—love the fat of the land—depend upon it, Sir, your sleek rosy rogue who laughs easily is "far better off than the respectable lean apothecary—he of the rueful countenance." I am, &c. M.R.C.S., L.A.C.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your Number of the 29th May contains the description and drawings of an apparatus for the reduction of dislocations, invented by Dr. Broxholme, and exhibited at the Medical Society. Though the apparatus is ingeniously contrived and well fitted for the purpose, yet the application of the screw to making the necessary extension in cases of luxation, was well known and commonly used by surgeons three hundred years since, as the following extract from Johnson's Translation of the Works of Ambrose Paré will prove:—

"Some Practitioners, instead of this pulley, make use of this described instrument, which they term 'Manuhrium Versatile,' or a hand-vice. The end thereof is fashioned like a gimblet, and is to be twined into a post. Within the handle lies a screw with a hooked end, whereto the string or ligature must be fastened. Now, the screw-rod or male-screw runs into the female by turning about of the handle, and thus the ligature is drawn as much as will suffice for the setting the dislocated bone."—Chap. vii., book 16.

An engraving of the apparatus is appended.

Yours, &c. A. WOLFF.

This Society is established to apply the principle of Assurance to Property as well as to Life; and its business consists of—

The ASSURANCE of DEFECTIVE and UNMARKETABLE TITLES, rendering them absolute and perfect.

The Amount of MORTGAGES GUARANTEED; by which Trustees, Solicitors, and others advancing money, are secured from loss, under any circumstances.

The ASSURANCE of COPYHOLDS, LIFEHOLDS, and LEASEHOLDS; thereby making them equal or even better than Freeholds, for all purposes of Sale or Mortgage.

The REDEMPTION of LOANS and MORTGAGES, and Guaranteeing their absolute Repayment within a given period.

MONEY ADVANCED on the PLAN of BUILDING SOCIETIES, without their risks and inconveniences.

INCREASED and IMMEDIATE ANNUITIES GRANTED upon Healthy as well as Diseased Lives.

The fidelity of CLERKS, SERVANTS, and all others GUARANTEED, upon the payment of a small Annual Premium, and a reduction of nearly one-half is made when a Life Assurance is combined with the Fidelity Guarantee Policy.

LIFE ASSURANCES effected for the whole Term of Life, or for a Term of Years, and the premiums can be paid either yearly, half-yearly, or quarterly.

ENDOWMENT and EDUCATION ASSURANCES and ANNUITIES granted; the Premiums can be paid upon the returnable or non-returnable system, in case of death before attaining the age agreed upon.

IMMEDIATE ANNUITIES or INCREASED INCOMES GRANTED in exchange for Reversionary Interests.

WHOLE WORLD POLICIES GRANTED, and all Policies issued by this Society are Indisputable.

Prospectuses, Forms of Proposals, and every information will be immediately furnished on application to William Neison, Esq., Actuary and Secretary, 30, Essex-street, Strand, London.

Every information furnished, free of expense, by applying to

WILLIAM NEISON, Actuary and Secretary, 30, Essex-street, Strand, London; or to any of the Society's Agents.

Charlbury, Oxfordshire. — Valuable

COPYHOLD PROPERTY.—TO BE SOLD by AUCTION, by JOHN MARGETTS, on THURSDAY, the 17th DAY of JUNE, 1852, at the BELL INN, CHARLBURY, near Enstone, Oxon, precisely at THREE o'Clock in the Afternoon, subject to such conditions as will be then produced, all that very desirable and substantially-erected Dwelling-house, situate in CHURCH-STREET, CHARLBURY, now in the occupation of W. Pollard, Esq. The House comprises 3 good Parlours, 6 Sleeping Apartments, Kitchen, China Closet, Brew-house, dry Cellaring, Stabling for 3 Horses, and Loft over Court-yard, Walled-in Garden, and all requisite Out-buildings.

The above will be sold subject to a yearly tithe-rent charge of 1s. 3d., and a quit rent of 1s. 5½d.

The above premises, until recently, have been the residence of a medical practitioner for nearly a century, and there is now an excellent opportunity for any one to obtain a first-rate practice. Charlbury is an improving and respectable town, with only one resident surgeon, situate in one of the most picturesque and beautiful parts of Oxfordshire, surrounded by seats of the nobility, and in the midst of many large and populous villages. The Oxford, Worcester, and Wolverhampton Railway, now near completion, runs close to the town, at which there will be a first-class station, thereby affording direct communication with all parts of the Kingdom.

To view the property, apply to Mr. John Horniblow, Charlbury; and for further particulars, to Mr. Allen, Solicitor; or the Auctioneer, High street, Warwick.

The New Equitable Life Assurance COMPANY.

(Incorporated by Act of Parliament, 7 and 8 Vic.)

SOLICITORS.

Messrs. Bell, Steward, and Lloyd, 59, Lincoln's-inn-fields.

The "NEW EQUITABLE" embraces all the advantages of a strictly Mutual Office, with the addition of an ample subscribed capital, forming a *bonâ fide* security for its policy-holders.

POLICIES INDISPUTABLE.

The Policies of this Company being Indisputable they become as readily negociable, in monetary transactions, as any other description of personal property.

INVALID LIVES

Are assured at rates adapted to the circumstances of each case. Every circumstance affecting the health impartially considered.

DIVISION AND APPROPRIATION OF PROFITS.

The whole of the Profits will be Equitably divided annually amongst the holders of Policies issued on the Participating Scale.

MEDICAL PRACTITIONERS.

The Directors acknowledge and consult all duly-qualified Medical Referees as the Medical Advisers of the Company, and uniformly transmit, with the Questions intended to be made the basis of every Official Medical Report, A CONSULTATION FEE OF TWO GUINEAS.

EXTRACT FROM THE DIRECTORS' FIRST ANNUAL REPORT.

The extent and character of the business already transacted by the NEW EQUITABLE COMPANY have exceeded the most sanguine expectations of its founder and zealous advocates. From the 31st of January, 1851, the date of the complete registration of the Company, to the 31st of January, 1852, inclusive, no less than *four hundred and forty-eight* proposals were received and entertained by the Directors. Out of this number of proposals *three hundred and fifty-five* policies were completed, and the remaining *ninety-three* have been either declined, or are not completed. The sum assured on the *three hundred and fifty-five* policies issued by the Company is *One hundred and sixty-eight thousand seven hundred and sixty-five pounds.* The premiums on the policies thus effected amount to *Six thousand and twenty-five pounds two shillings and sevenpence* per annum, the average amount of the policies being nearly *Five hundred pounds.*

These facts afford matter for earnest congratulation to the Directors, the shareholders, and the assured. If the extent of the operations of the NEW EQUITABLE, during the past year, be compared with those of other Companies, it will be seen that there are very few of the oldest Life Offices, even of the first class, which have transacted an equal amount of business. It is demonstrated by the balance-sheets of offices in the best repute, as published from time to time, that after ten, twenty, or even thirty years of experience and consolidation, many of them have not equalled, in the year just ended, the infant labours of the NEW EQUITABLE.

Policies never disputed.

All descriptions of life assurance business transacted, and every facility given for payment of premium.

Prospectuses and further information may be had at the Chief Office, or of the Company's Agents.

Chief Offices—449, WEST STRAND, CHARING-CROSS, LONDON.

Rev. J. Lane, Saltash Parsonage,

PLYMOUTH, and many others, lately cured with the delicious and reasonable ALE, brewed with the water from "Harry Hill's Well." By tradition H. Hill was wonderfully cured in the 16th century by the water. "*Ergo bibas—iterumque bibas; mox conscia vitæ splendebit roseo picta colore gena.*"—B. HOLDEN, 55, Upper Seymour-street, Portman-square, sole London agent. H. Watts, Manager Stogumber, Taunton. One agent appointed to a town. October brewings are now in prime order.

Umbilical Hernia.—Bourjeaurd's Abdominal Supporter and Air-Pad.

M. Bourjeaurd begs to direct the attention of the Profession to his newly-invented Belt and Air-Pad for Umbilical Hernia. This ingeniously-contrived apparatus will be found of immense value with children, where springs and hard hemisphere generally act injuriously. The child (or adult) wears the Belt with perfect ease and great comfort. The Pad may be made more or less resisting, according to the nature of the case, and the yielding nature of the air insures the patient against the undue pressure which is but too often resorted to. This Belt need but be generally known to be generally adopted.—See the "Lancet," July 12, 1851, page 33, Mirror of Medicine and Surgery.

10, Davies-street, Berkeley-square, opposite Mivart's Hotel.

M. Bourjeaurd will be happy to show the Belt, and explain the principles to any member of the Profession, any day (Sundays excepted) from One to Five p.m. Entrance at private door.

To the Medical Profession.—The

attention of the Profession is respectfully invited to GLASS'S PURE WHITE GELATINE, recommended for making a first-rate Blanc-Mange, or Jelly, suitable for invalids, superior to Isinglass, having no fishy smell, and one half the price, in 6d. and 1s. packages. To be had, wholesale at the Steam Works, Brandon-street, Walworth; and at all respectable grocers and chemists in the country. Also retail in London of the following Agents—Petty and Wood, King William-street, City; Marshall and Co., 20, Strand; Back, grocer, 123, Tottenham-court-road; Graham, Ludgate-hill; Robert Ash, 211, Borough; Handford and Davies, 61, High Holborn.

Shower and all Domestic Baths.—

Purchasers of these valuable and important family requisites should immediately inspect DEANE, DRAY, and CO'S EXTENSIVE STOCK, warranted the best manufactured, both for finish and durability. Deane, Dray, and Co.'s RECUMBENT SHOWER BATH forms at the same time an excellent Sponging Bath, and may also be used as a Hip Bath, thus affording to all the members of a family the various applications of the bath. Shower Baths of improved construction, Hip, Plunging, Sponging, Vapour, and other Baths, of various sizes and patterns. An illustrated pamphlet on Baths and Bathing, may be had on application, or free by post. —Established A.D. 1700.

DEANE, DRAY, and CO. (opening to the Monument), London-bridge.

Kidston and Co., 18, Bishopsgate-

STREET WITHOUT, LONDON, Manufacturers and Dealers in every description of Medical Shop Fittings, Glass Cases, Soda Water Stands, Specie Jars, Medical Glass Surgical Instruments, and Druggists' Sundries.

KIDSTON and CO. having had practical experience in manufacturing for upwards of twenty years, are enabled to supply any of the above articles, of superior design and workmanship.

A New Catalogue of reduced prices may be had on application.

Plans and estimates furnished on the shortest notice.

Experienced workmen sent to any part of the kingdom.

β QUININE, OR SULPHATE OF QUINIDINE,

A New Alkaloid discovered in the

Cinchona Barks.—The attention of the Medical Profession is solicited to this new and important Alkaloid, as its medicinal effects are reported to be quite equal to the Sulphate of Quinine. It is more soluble in water, has the same crystalline appearance, and is much cheaper in price than sulphate of quinine.

May be obtained in any quantity of William Henry Cole and Co., Wholesale Chemists, 101, High Holborn, London.

Also, Quinoidine, Quinine, Cinchonine, Salicine, Tannin, Strychnia, Pure Creosote, Chloroform, Santonine, Ergotine, etc., etc.

Prices may be obtained on application.

James's Powder.—Physicians and

other Medical Practitioners having complained of the frequent use of Antimonial Powder, instead of the "Genuine James's Powder" prescribed, have represented to Messrs. Newbery, that the price of the powder has greatly led to this fraudulent practice, and has also greatly prevented the more general use of the powder. Messrs. Newbery have, therefore, yielded to the suggestions of the Profession, and have reduced the price; and, to secure the use of the genuine medicine, recommend that the same should be prescribed as prepared by Messrs. Newbery, thus—"Pulv. Jacobi Ver," (Newbery's.) The price for dispensing will henceforth be reduced from 21s. to 9s. an ounce. The genuine has the name "F. Newbery, 45, St. Paul's," engraved on the Government Stamp.

For Varicose Veins and Weakness. —

SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, on a New Principle, pervious, light in texture, and inexpensive, yielding a permanent, efficient, an unvarying support under any temperature, without the trouble of lacing or bandaging. LIKEWISE, A STRONG, LOW-PRICED ARTICLE FOR HOSPITALS AND THE WORKING-CLASSES. ELASTIC NET CORSETS of the same beautiful Fabric. ABDOMINAL SUPPORTING BELTS, for both Sexes; those for ladies' use before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instructions for measurement, and prices, on application, and the articles sent by post from the Sole Manufacturers, POPE and PLANTE, 4, Waterloo-place, Pall-Mall. THE PROFESSION, TRADE, AND HOSPITALS SUPPLIED.

Important to Surgeons requiring In-

STRUMENTS to DESIGN.—BLACKWELL (Working Surgeons' Instrument, Razor Maker, and Cutler), 3, Bedford-court, Covent-garden, London, solicits attention to the above, and respectfully invites inspection of an extensive stock of Surgeons' Instruments and Cutlery (guaranteed best London make), and offered at moderate prices.

Army and Navy Surgeons' Outfits at an hour's notice; and a Variety of Cases, equal to new, for Navy and Emigrant Surgeons, cheap.

ORIGINAL LECTURES.

CLINICAL LECTURE

DELIVERED AT

St. Bartholomew's Hospital.

By EDWARD STANLEY, Esq., F.R.S.

ON SCROFULOUS AND RHEUMATIC INFLAMMATION OF JOINTS.

Gentlemen,—The class of affections to which I propose to draw your attention this morning, has been adverted to by me on former occasions; but, inasmuch as it comprises diseases of common occurrence, and of the highest importance, it can scarcely be too often considered by the surgeon. Affections of the joints, indeed, and their lamentable consequences, whether resulting from neglect, unskilful treatment, or the inveterate nature of the complaint, are so repeatedly exemplified in the patients who apply at this hospital for relief, that I need offer no apology for describing maladies, a thorough knowledge of which is absolutely essential to the practitioner. In hospital practice, however, we seldom see the early stages of joint affections; patients come emaciated by long suffering, in whom the disease has advanced beyond the period for successful interference, in whom, possibly, disorganisation of the articular structures has commenced. In private practice, on the other hand, we are often called to treat these diseases at their outset; and it is with a view of rendering you acquainted with symptoms and phenomena of which the practice of a large hospital affords but few illustrations that I again lay the subject before you.

It cannot have escaped your notice, how frequently we encounter disease in some joints, how rarely in others; some, indeed, seem almost, and some entirely, exempted. Affections of the knee and hip-joints are daily seen; but seldom do we meet with disease in the joint of the lower jaw, or in the sterno-clavicular articulation. Again, the articulations between the heads of the ribs and the bodies of the vertebræ, and between the costal tubercles and the transverse processes of the vertebræ, seem to be never attacked by primary disease. At least, I am unacquainted with any morbid specimen in the museums, or with any instance in the records of pathology, exemplifying such an affection. These joints, I am aware, become involved in secondary mischief; disease commencing in the vertebræ may extend to them; but this constitutes another order of cases, an order to which my remarks are not applicable, and to which I do not refer. I speak not of implicated but of original disease; and I repeat, I am ignorant of any example illustrative of original disease in the joints which I have specified. It is asserted, that an explanation of the diverse liability of joints to disease,—the local predispositions of some, and the local immunities of others,—is to be found in their greater or less exposure to external influences; and that the knee is especially liable to disease, because especially exposed to such influences, both from situation and the thinness of its coverings. This explanation, however, is inadequate, for the hip-joint is surrounded by thick coverings of soft parts, and perhaps less exposed than any other; yet how frequently is it attacked! The ankle-joint, on the other hand, is thinly covered, and quite as much exposed as the knee; yet how rare, comparatively speaking, are its affections! Physiologists have stated, that joints are susceptible of disease in proportion to the activity of their functions,—that is to say, the more a joint is worked, the more likely is it to suffer impairment. Now, I apprehend, few joints are more exercised than that of the lower jaw; but we all know that few are more free from disease. Such a doctrine, moreover, involves a needless impeachment of the original integrity of the structure.

Rare, however, as disease of the temporo-maxillary articulation undoubtedly is, I exhibit to you two specimens of its occurrence. One (specimen 27 of the 2nd series of the Pathological Museum of St. Bartholomew's Hospital, vide Catalogue, Vol. I., p. 95) is the base of a skull, in the right glenoid cavity of which, ulceration, commencing in the surface, has extended both widely and deeply in the adjacent bone, and new bone is formed around the ulcerated surface. The other specimen (42, 2nd series, vide Catalogue) is a portion of the base of a skull, exhibiting partial absorption of the surface of the glenoid cavity, the effect of disease in the articulation of the lower jaw. Both these specimens were obtained from subjects brought into the dissecting-rooms; their history, therefore, is unknown; but they clearly demonstrate the existence of ulcerative disease for some time before death. There is a third specimen in the Museum, (1st series, sub-series a, p. 71 Catalogue,) in which, conjointly with ulceration in several parts of the cranium, there has been disease in one of the articulations of the lower jaw, producing absorption of the articular cartilage, with a deposit of bone in the circumference of the glenoid cavity. The corresponding condyle is in part removed by absorption." This, however, is an example of syphilitic disease.

In a late number of the *Medico-Chirurgical Review*, there is a notice of some cases recorded by Dr. Wernher,—examples of anchylosis between the upper and lower maxilla at different points. Some of these cases fell under the personal observation of the author, others are collected from pathological reports. Anchylosis is, as you are aware, of two kinds; either bony, resulting from osseous deposit, uniting one bone to another, as the tibia to the condyles of the femur, the neck of the femur to the acetabulum; or false, fibrous anchylosis, produced by inflammation within the joint, resulting in the adhesion of synovial surfaces; or by inflammation without the joint, producing thickening and condensation of tissues, by exudation of lymph. This latter form, since the introduction of chloroform, has been placed more under the control of the surgeon; for, with the aid of that narcotic, it is practicable to break down the adhesions by forcible flexion of the rigid member, and so to restore some degree of function to the joint. And here I would observe to you, that the tissues in and immediately around a joint are tissues of low vitality, not possessed in any great degree of the forces which withstand disease, or are able to repair its devastations. Although, when inflamed, they become acutely sensitive, in the natural state they are almost devoid of feeling. Relative to this point, the experiments of Bichât are particularly interesting; he discovered that the middle of a long bone possesses more sensibility than its articular ends, for injuries to the middle of the shaft in animals caused cries and evident indications of pain, while injuries to the articular ends caused little pain, and seemed to be but slightly regarded by the animal. These experiments I have repeated, and can confirm their results.

I now come to the consideration of strumous inflammation of joints, and, before proceeding to investigate its phenomena, the following questions demand attention:—1st. What are the circumstances which would lead us to regard the disease as strumous, when brought to the bedside of a patient? 2nd. In what condition should we expect to find the structures, viz., the bones, cartilages, and synovial membranes of a joint, provided the disease be strumous? With reference to the first question, I am unacquainted with any local symptom, any precise condition in the affected joint itself, which would enable us at once to decide on its strumous nature. We must look elsewhere. The age and aspect of the patient, the past or present existence of scrofulous disease in other parts, such as enlargement, and suppuration of the cervical absorbent glands, strumous ophthalmia, tubercle in the lungs or others organs,—any of these, especially if actually co-existent, would justify us in regarding the disease as scrofulous. Often, indeed, these cases are obscure, and sometimes we are led to a wrong conclusion. The aspect of the patient is delusive, and should not be too much relied upon. Many instances occur in which the patient's appearance seems indicative of the existence of scrofula, whose subsequent progress and favourable recovery prove that such evidence is fallacious.

We have now to answer the second question. What is the state of a joint invaded by strumous disease? The morbid specimen I now exhibit shows the condition of the articular extremity of a bone in an extreme attack of this nature. The end of the bone is softened from absorption of its earthy matter, and its cancelli are filled with tuberculous deposit. It is, however, according to my experience, rare to meet with so complete an example of strumous disease as this specimen furnishes. In the majority of cases, I believe that no tubercular matter is found deposited, and, when found, it is only in the last stages of the affection. Such a condition of bone, when it does exist, is, in my opinion, irreparable; and, when the surgeon is summoned to a case exemplifying the disease in this its latest stage, he can do nothing to restore the bone to its natural state, nothing to accomplish a cure. There is, however, an earlier stage in these affections, which you will often have to treat in private, although it is seldom seen in

hospital practice—a stage amenable to treatment, a stage in which, generally speaking, the morbid impairment of the bone may be arrested, and its integrity restored. It is characterised by increased heat, and enlargement of the bone immediately above the joint. There is, indeed, increased vascularity, and low inflammation of the bone, which is quickly followed by expansion of the cancellous texture, and absorption of earthy matter. Ultimately, in bone thus degenerated, tubercle is sometimes deposited. Such, then, is the state of the bone in a joint affected with struma. The other structures,—the cartilages, synovial membrane, etc., are in a state of low inflammation,—inflammation which has commenced either in the bone or the synovial membrane itself, and which, if suffered to advance, is followed by its usual consequences,—exudation, thickening of tissues, and sometimes suppuration. Now, the appropriate treatment for an attack of this sort is, perfect rest for the limb, and removal of all weight and pressure from the inflamed joint, so as to insure, as far as possible, its complete tranquillity. If inflammation exists in any activity, the judicious application of leeches will be beneficial; but it should be borne in mind that leeches must not be lavishly employed, as strumous patients cannot stand depletion. The remainder of the treatment is constitutional, and should be directed to the restoration of the general health, if that has failed; to its maintenance, if it has not. To this end country air, or, where it is practicable, a resort to the sea-side should be recommended; a light, nutritious diet enjoined, and the state of the stomach and bowels be carefully attended to. The following particulars of a case which occurred to me some years ago, illustrate forcibly the truth of my observation, that the articular ends of bones rarely become the seats of tubercular deposition, even in well-marked examples of strumous disease.

A boy, ten years old, was under my care for scrofulous enlargement and suppuration of the cervical glands. While in the hospital, hip-disease supervened, evidently of strumous character, which ultimately wore out the patient. Examination of the body showed, that the joint was disorganised; the soft tissues around were infiltrated with tubercular deposit; the capsule and articular cartilages partially destroyed by ulceration; the bone was dislocated on the dorsum ilii; the acetabulum widened, and containing tubercular matter. The mesenteric and other absorbent glands were infiltrated with tubercle. Tubercular ulceration was present in the intestinal canal. However, when a longitudinal section of the head of the femur had been made, no tubercular deposit was found in the interior of the bone. Absorption of earthy matter, and widening of the cancelli, had taken place, but no interstitial tubercle existed.

Not infrequently disease in the soft tissues around a joint, inflammation, and abscess, are mistaken for disease inside the joint; and, in some instances, eminent surgeons have amputated limbs under the impression that an irremediable articular affection existed, while, in reality, the exterior tissues alone were involved, the joint itself being sound.

Joints are liable to another form of inflammation, differing from that which we have just reviewed,—"rheumatic inflammation." Examples of this disease occur generally in combination with rheumatic fever, and are therefore more prevalent in the medical than in the surgical wards of the hospital. The diagnosis of articular rheumatism is not usually difficult. When rheumatic fever is present, it is, of course, obvious; but when it is not, the implication of other joints, the cause and symptoms of the attack, and the history of prior rheumatism, will generally guide us to a right decision. The implication of other joints, because it is extremely rare to find rheumatism affecting one joint only. It attacks two or three simultaneously, or flies about from one to another. The cause and symptoms of the attack,—because we shall almost invariably find that the patient has been exposed to cold, or dampness, and because muscular pains are generally precursory to the articular inflammation. Rheumatic disease thus induced, is commonly marked by pain in one particular spot; the patient does not complain of general pain in the joint, but points to one especial locality, and describes it as the seat of all his sufferings.

Articular rheumatism is, moreover, intractable, leaving one joint and assailing another, or departing and recurring in the same joint. Joints are attacked by rheumatic inflammation in two ways: either their fibrous structures, their ligaments suffer, or their synovial membranes. Now, the consequences of rheumatic inflammation of the ligaments may be serious, such, indeed, as may terminate in dislocation of the bones of a joint. For, under its influence, the ligaments become soft and elongated, so as to permit the bone to slip out of the cavity in which it is naturally fixed. In this way the head of the femur may be displaced upwards on the dorsum ilii without rupture or ulceration of either the capsule or the ligamentum teres. An example of such an occurrence happened some years ago in the practice of Mr. Lloyd.

A painter, in the enjoyment of good average health, was in the habit each morning of taking a warm-bath. After having done so on one occasion, he experienced a pain in the hip-joint, one of the joints of the fingers also became swollen and inflamed. He consulted a medical man, who gave him hopes of speedy recovery. Nevertheless, he remained in bed five weeks, after which, the pain having subsided, he was told to get up: this he found himself totally unable to do, and, on examination, the limb was found to be shortened and inverted, the head of the bone having been dislocated on the dorsum ilii.

A case has also been related to me by Dr. Latham, in which articular rheumatism of long continuance produced dislocation. Some years ago, a young woman was in the hospital, under the care of Mr. Lawrence, suffering from rheumatism in the hip and wrist joints. She was confined for some time to her bed, and when permitted at length to get up found that she was lame, and that the lameness grew gradually worse. After a while she experienced a sensation as if the bone slipped from the socket when she walked. On examination, the limb was found of natural length, and its movements complete; rotation, however, was remarkably free; and when the thigh had been flexed on the pelvis, and was then rotated, the head of the bone could be evidently felt to pass over the brim of the acetabulum.

Cases like these illustrate the unusual results of a very common affection, which, although often obstinate and tenacious of existence, generally terminates well, leaving an unimpaired joint behind.

Rheumatic synovitis commonly ends in effusion. Ulceration of the articular cartilages may, however, supervene; and I have witnessed a case in which this condition was set up within nine weeks from the commencement of the attack, so that it was found necessary to amputate the limb. More usually, however, rheumatic synovitis gives rise to anchylosis, such anchylosis as may result from the adhesion of opposite synovial surfaces by effusion of fibrin, and which, as I have explained in an early part of the lecture, is called spurious, in contradistinction to true or osseous anchylosis.

Gonorrhœal rheumatism is a form of the disease occurring in conjunction with gonorrhœa, brought on by exposure to the vicissitudes of weather, and to the development of which, a certain unhealthy constitutional state appears necessary. Unlike ordinary rheumatism, it confines itself to one or two joints, and unshifting, clings to them with remarkable tenacity. It is, in truth, an affection that has long baffled the powers of medical surgery. In many instances the patients appear to recover, but the complaint returns on the slightest exposure, and no permanent cure is effected. There is now under my care, in Lazarus, a Pole suffering from gonorrhœal rheumatism of the wrist joint. In him the disease has yielded for the present to three grain doses of the iodide of potassium, given three times daily; and, I am informed, that the gonorrhœal discharge, which had become scanty, has re-appeared since the mitigation of the articular disease. The best possible termination in these cases,—a termination which has ensued in the instance I have mentioned, is serous effusion into the joint; for when the fluid is absorbed, it is not unlikely a useful joint may remain. Some time back, a young man, aged twenty-one, was my patient in the hospital, in consequence of almost acute attack of rheumatism in the shoulder-joint, following gonorrhœa. Though he was in a reduced state, I ordered him to be bled from the arm; mercury was administered; in fact, very active treatment was adopted. Serous effusion into the joint resulted, and within five weeks I had the gratification of seeing him leave the hospital with the functions of the joint in a great measure restored.

We occasionally meet with examples of rheumatic synovitis, occurring after parturition, which may originate anchylosis. The affection differs in no shape from ordinary rheumatic synovitis; but it requires gentle treatment, as the patients attacked by it are generally much debilitated, and frequently suffering from some uterine complication.

ORIGINAL COMMUNICATIONS.

SOME GENERAL OBSERVATIONS ON FATTY DEGENERATION.

By WILLIAM FREDERICK BARLOW, M.R.C.S.

Resident Medical Officer to the Westminster Hospital.

[Read partly before the Medical Society of London, March 20, 1852.]

[Concluded from page 493.]

But now let us proceed to the consideration of those *local* obstructions to the circulation, which occasionally constitute that true, although partial anæmia, whereunto succeed atrophy and, by no means uncommonly, fatty degeneration. The coronary artery may be so obstructed as to lead to *local* fatty degeneration of the heart,—a fact already most fully and clearly illustrated by Dr. Quain.(a) Softening of the brain has often been found connected with, and rightly considered consequent upon, a narrowing of the arteries leading to the affected part; and there can be no doubt that, generally speaking, arrestations or diminutions of the current of blood, wherever they may happen, lead to atrophy and decay. Impaired nutrition of the lower extremities has been traced to congenital constriction of the aorta. The size of parts may, to a certain extent, be figured by the diameters of the vessels leading to them, although remarkable exceptions to this exist, which are readily explained by physiology.

Mr. Simon has made the observation, that partial atrophy and softening of the kidney may be traced sometimes to the blocking up or obstruction of a small artery.

In one case, he noted a vessel of this kind "blocked completely with an atheromatous and fibrinous mass, which had probably been carried into it from some larger trunk, and had thoroughly arrested the passage of blood there."(b)

The condition of the vessels in regard to the whole question of atrophy and degeneration needs a more methodical treatment than it has yet received; it can only be glanced at here. Occasionally, we find a branch of an artery so obviously occluded, and the part it supplies so exclusively degenerated, that no doubt remains about the impairing or withering influence it has exercised. But local degeneration may occur from obstructions occurring in vessels not easily traced, nay, of those which are of quite microscopic minuteness, such, for instance, as those of the brain, described and figured by Mr. Paget as degenerated in apoplexy.(c) Nor does it follow, that the small blood-vessels should be healthy, because the large ones appear quite untouched. In several cases of ramollissement of the brain, I have observed the most obvious degeneration of the minute, when there was none observable in the larger vessels; but it will be often quite impossible to say how much is due to the state of the vessels, how much to the condition of the blood itself, and how much to the defective assimilation of tissues; the latter has often most undoubtedly a large share in the process of destructive conversion.

An artery is sometimes found to diminish from the disuse or paralysis of its field of distribution; and the lessening of its size may become, in some instances, a serious bar to the recovery of a part which needs all auxiliaries to the restoration of its pristine state of nutrition.

The effect of the obstruction, or narrowing of vessels, is much modified by various circumstances. The consequence of the diminished calibre of a vessel may be fully counteracted by the compensatory enlargement of other channels; but if there exists, as frequently happens, a diseased state of the neighbouring artery, or branches of arteries, nature may be foiled in any effort to carry on the circulation with effect.(d) Portal refers to a case of apoplexy, in connexion with which there was discovered so great an ossification of the right internal carotid that scarcely any blood could have found way through the channel; but the vertebral of the same side was three times bigger than its fellow, and had, doubtless, supplied parts which would have perished but for its enlargement. But the heart is deprived, by an anatomical peculiarity, of the establishment of a collateral circulation in cases of obstruction of the coronary artery,—a fact which has not escaped Dr. Quain, who cites, in his Memoir, Mr. Swan's observation, that there is no communication between the branches of that vessel, and points out the necessary consequence resulting in cases of local degeneration dependent on their being blocked up or narrowed. The like peculiarity of the pulmonary circulation has been noticed by Mr. Paget in his observations on obstructions of the branches of the pulmonary artery. "From the arrangement of the pulmonary arteries, between which there is no anastomosis except in their capillaries and smaller branches, it results that, whenever the flow of blood through the capillaries of any part of a lung is prevented, there must also be a stagnation of blood in all the branches from which those capillaries are derived; and in those circumstances the blood coagulates in the vessels, and passes through various changes."(a)

But the collateral and effectual supply of the brain and other parts in cases wherein their blood-channels are diminished, is, of course, entirely contingent. If the arteries in the neighbourhood of the diseased spot happen to be healthy, the exigency of the situation may be met; but the degeneration of vessels may be so extensive, that the conservative influence of anastamosis is wanting, and the part which is supplied by the obstructed vessel perishes as a consequence. The success of the ligature of the carotid artery must be greatly modified by the general condition of the cerebral bloodvessels, both large and small. It may be impossible adequately to re-establish the circulation through fresh channels, in consequence of their diseased or degenerated state; and the brain may be so impaired in nutrition, that any impediment to its circulation may lead quickly to softening. It was stated by Mr. Hodgson, at a recent meeting of the Royal Medical and Chirurgical Society, that, in the great majority of cases wherein ramollissement had followed the tying of the carotid artery, the patients had passed the middle age of life; and one, seeing what recent researches have taught us, may be pardoned a speculation on the probable condition of the bloodvessels of those persons, and their influence on the issue of their cases. The small bloodvessels of the brain, as well as the large, might have been more or less affected by degeneration. Aneurism of the larger arteries is frequently associated with other aneurisms. Degeneration of the heart and bloodvessels generally may be looked for reasonably in aneurismal subjects. In the case of an abdominal aneurism, which I have laid before the Pathological Society, occurring in a woman twenty-nine years old, there was found a heart degenerated into fat, and a circumscribed softening in the cerebellum, the small bloodvessels in its neighbourhood presenting distinct clusters of fat granules in their coats.

In applying observations made upon the ligature of the arteries of animals to the treatment of aneurism in the human subject, it must never be forgotten that, in the case of experiment, we operate in a condition of health. If a part be degenerated, and all its vessels more or less diseased, the artery leading to it cannot, of course, be ligatured so safely as under the favourable circumstance of perfect nutrition.

That there were local causes which would greatly modify and interfere with the circulation of the blood was well known to, and insisted on by, its famous discoverer;(b)

(a) "Medico-Chirurgical Transactions," Vol. XXXIII.

(b) *Op. cit.*, p. 94.

(c) *Medical Gazette*, 1850; see also a subsequent communication by the writer in the same journal for 1851.

(d) The serpentine convolutions which arteries are wont to make when they enlarge, are admirably described by Dr. William Hunter:—"The coats of arteries are elastic, and therefore whatever distends must, at the same time, lengthen them, and thereby produce serpentine turns. I observe that this happens constantly in injecting the vessels of dead bodies; and I have often had opportunities of observing the same thing happen from the stroke of the heart in the arteries of living animals. In the snake or viper it is very apparent in an artery that runs along the outside of the lungs, which is thrown into serpentine windings every time that it is dilated by the action of the heart." He further refers to the aorta of a woman, which, "from being enlarged, had become so long that it could not run straight down the back as usual, but made gentle windings all the way." Arterial changes like these cannot, of course, happen where the vessels are made rigid by degeneration, or are so weakened at certain points that aneurism is the consequence of the blood's impulse. See "Medical Observations and Inquiries;" or Mr. Erichsen's Collection of Observations on Aneurism," published by the Sydenham Society, p. 169.

(a) "Medico-Chirurgical Transactions," Vol. XXVII., p. 163.

(b) I shall cite the passage to which I here refer. Let us apply what he says of obstructed circulation to cases of atrophy, degeneration, softening, and what he observes of the altered consistency of the blood to the changed condition of that fluid which we have had too ample opportunities of examining in cholera:—"Veruntamen exinde manifestum est sanguinem, in suo circuitu, non eadem velocitate et celeritate ubique transire: ut neque eadem vehementia, in omnibus locis et partibus et temporibus, sed pro ætate, sexu, temperie, habitu corporis, cæterisque rebus contingentibus, internis vel externis, naturalibus vel non naturalibus multum variari. Non enim per vias et mæandros occlusos, obstructos aut impeditos, eadem celeritate transit, qua per apertos, reseratos, et patentes; neque per corpora

and what may be effected by these, we see well exemplified in that general degeneration of the arterial system into which fatty conversion largely enters. But study that extensive degeneration as we will, we can never behold it as it fully exists. What! though we begin with the aorta itself, and thence trace the blood-vessels to every organ, and follow them into each, so far as we are able, and scrutinize their coats with curious attention, and, with regard to the vessels of the brain, do more, and, by microscopical assistance, bring the remotest of them into clearest view, and mark their degenerations, dilatations, and the state of their surrounding tissue, selecting them from various parts of that wide-spread and intricate vascular mesh which intervenes between the great arteries and veins of the organ, and comparing them diligently as to their different appearances, we shall, notwithstanding, be obliged to leave unexplored the great mass of blood-channels, even in this structure: and what, we may ask, is the state of the small arteries and veins of the heart, the lungs, the liver, the kidneys,—what, in a word, is the minute pathology of all the blood-vessels of every part? It is often hard, nay, impossible, to say, whether a vessel leading to a softened part have degenerated with or before it, and especially in old age and chronic maladies, in which, frequently, the blood, and its vessels, and the places it flows to, may be held to decline simultaneously. How, for example, can we sometimes say whether the arcus senilis be really an effect, or simply an association of that atheromatous condition of the ophthalmic artery which Mr. Canton has found to be connected with it. Much might be said if the corneæ and their arteries were exclusively degenerated,—more, if one arcus senilis only were found, and one ophthalmic artery only affected; but the adipose arc or circle is connected commonly with a diffuse, all-pervading evidence of decay. Yet, in cases even of the most general kind, we shall still find local modifications; here and there vessels will be perceived unusually obstructed, and, moreover, at the express points of lesions, which are far in advance of the general decay. May not the fawn-coloured patches which significantly mottle the degenerated heart, be each, in some instances, owing to obstruction of its own appropriate arterial branch or minute ramifications? May not the circumscribed diffused softenings, occasionally seen in capillary apoplexy, be centres of an extreme vascular degeneration? The true relation of a vessel to the atrophy, wasting, and death of a part, can be known only by completely tracing it throughout its course. Anæmia of the brain may, as Rokitansky reminds us, be produced by degeneration at the aortic orifices of the cerebral blood-vessels,(a) and, though the whole length of them seem free from disease, so far as the unaided eye can reach, the microscope may find their terminal channels more or less fatty or calcareous.

It seems to me, that the state of the minute circulation has not been at all sufficiently considered in reference to the softening and destruction of parts. It has been inferred, in some cases of ramollissement of the brain, that the obstruction of the artery leading immediately to the destroyed part has been the direct cause of its death; but the only support of this position is to be found in the existence of a coagulum of blood in that artery. It is my belief, that in many cases of local death, not of the brain only, but other parts, the obstruction of the artery, or branch of artery, leading directly to the mortified spot, has been the consequence, and not the cause, of the affection. That the occlusion of the ramifications of an arterial trunk may arrest the blood in its onward course, and lead to its coagulation, is too clear to be insisted on. The mortification of a limb would necessarily impede the main artery and its branches, and fill them with coagula. More limited impediments would, of course, produce more restricted effects. Mr. Paget tells us, in his observations on obstruction of the pulmonary artery, that the branches which run to an inflamed spot of lung may become filled with coagulated blood; and, in like manner, a gangrenous part may obstruct the vessels which once nourished it. These remarks refer exclusively to cases in which the large arteries are found simply blocked up, and not to those, I need hardly say, in which they have been evidently a long time narrowed, perhaps almost occluded, in consequence of degeneration.(a)

III. *The influence of the nervous system* being most closely related to nutrition itself, must be considered in reference to its failures; and it must be regarded under the separate heads of withdrawal and derangement. Parts waste in paralysis; and we may be quite certain, that, in the general impairment of functions in old age, the wasting and degeneration of various structures are often heightened by that disease of parts which results from the growing lethargy of the mind. To what Mr. Paget and others have remarked of the local consequences of the partial withdrawal of nervous influence, I have nothing to add; but I cannot pass over, however difficult the subject may be, the question of the disturbances and losses of nutrition effected by various conditions of the mind. How hard to define the measure of their mischief, and yet how easy to perceive that it is vast! The state of the mind often injures nutrition, in an indirect manner, by withdrawing the body from those exercises and diversions which constitute main sources of its vigour; by depressing the heart's action, so that the blood is circulated with insufficient frequency and force; by modifying the respiration so extremely, that the oxygenization of the blood is less perfect than it should be; by seriously interfering with the digestive function, the disorders of which spread through the body; and oftentimes by banishing or breaking the sleep, "chief nourisher in life's feast."(b) It cannot but be concluded, from a variety of considerations, that growth, nutrition, reparation, and decay, are extremely affected by the conditions of the mind. Practically, men act as if they were so; and the great students and expounders of human nature have drawn most terrible and striking pictures of the body withering from sorrow or despair. All ages and stations testify to their truth. Youth may anticipate both the toil of mind and the cares of manhood,

> "Ante annos animumque gerens curamque virilem;"

but it is on the aged, the atrophied, the partly degenerated, that the depressing passions tell most fearfully. We cannot graduate their degrees of effect as we can measure those of heat by a thermometer: but shall we doubt their existence, because we cannot weigh their consequences in an unerring balance? We must reflect delicately on the subject of life. The best thoughts on this matter are too subtle for expression. Eloquently as Bichât wrote, he left, doubtless, much unwritten which he felt was true; and many of Hunter's greatest thoughts came, probably, when he was busily dissecting, and fled with the moment. Each transient emotion which affects the breathing, or agitates the heart, alters nutrition everywhere. Vast, then, must be the sum of such influences, to say nothing of passions which rage terribly, of griefs which time cures not, throughout a life-time never safe from emotion, no, not even in sleep! Vast the effect of some master-passion, which, concealed or visible, withers the body by its ceaseless tumult, recalling, it may be, to the minds of many, that noble passage of our famous Dryden, wherein he paints—

> "A fiery soul, which, working out its way,
> Fretted the pigmy body to decay,
> And o'er informed the tenement of clay."(c)

The plant is exempted from a multitude of sources of deranged nutrition, which are quite restricted to a higher life. It may be checked in its growth, its flowering, its fructifying, by various agencies material in their kind; it may be killed by cold, or destroyed by blight, or wither from the ungenial nature of its soil,—may be exposed to the changes and tempests of the air; but it is free from all mental vicissitudes and storms. And certain we are that the existence

aut partes densas, constrictas, infarctas, uti per raras, relaxatas et de obstructas. Neque cum debiliter, lente, et molliter sit impulsus, ita expedite procurrit aut penetrat, uti cum vi aut rohore impingitur, vehementia et copia cogitur. Neque crassus ipse sanguis, aut solidior, aut terrestior factus, adeo penetrativus, uti cum serosior, attenuatus, liquidior existit."—*Gulielmi Harvei Opera Omnia a Collegio Medicorum Londinensi Edita*, p. 128.

(a) Translation of Rokitansky's Pathological Anatomy, Sydenham Society's edition, p. 885.

(a) Dr. Marshall Hall, as I learn from conversation with him, takes the view here stated, of the manner in which the larger vessels *may* become obstructed.—(See a note in his Croonian Lectures, delivered in 1851, p. 88.) In watching with Dr. Hall the circulation of the blood in the web of the frog, I have had frequent opportunities of seeing how many causes may modify its flow through arteries, veins, and capillaries. Perhaps we can never truly feel all the importance of a free and sufficient circulation to a part, unless we observe carefully the wonderful scene of the blood traversing the minute vessels, as shown by the microscope. The circulation, as beheld in the toad's lung, is splendid and striking beyond description.

(b) We term sleep a death, and yet it is waking that kills us, and destroys those spirits that are the house of life."—*Sir Thomas Browne.*

Sydenham emphatically says:—"Etenim post venæ sectionem et catharsin nihil æque naturæ vires subruit ac noctu vigilare."—*De Podagra.*

(c) Absalom and Architophel. On many matters relative to the connexion between mind and body, not a few of us, conscious that we may fail in expression, turn to the great masters of our noble language, whether they have written in poetry or prose.

of man is often shortened by the adversities of his fortune, or the unhappy constitution or management of his mind; nor is the general opinion held on this point to be set down coolly amongst "vulgar errors." His life is formed by the combination of processes which, times and often, mingle together, and are lost in each other, as wave in wave; they cannot be compared to a number of lines placed parallel, with intervening spaces, so that all may be seen with great distinctness; nor yet to a web, such as that of the spider, in which the threads, though arranged more complexly, can all be most clearly and easily traced; but they are rather to be likened to the mingling of colours, whereby effects are caused, whereunto we perceive certain tints are essential, though we fail to discover those exact proportions which are known only to the artist who has mingled them. And so in disease,—we know often the causes, or many of the causes, which are working for death, and incessantly spoiling the wonderful structures; and yet fail of assigning, with anything approaching geometrical precision, their true parts to each; they all work together so simultaneously, and with such mutual aid, the body lowering the energies of the mind, and the mind impairing the strength of the body, that we can only speak of the *relative* influence of the destroying powers as of a matter of probability; but, here great judgment may be shown, and high evidence of reason and knowledge; nor must we refrain from treating of problems because they are complex; for the whole great question of life and death might well be abandoned on this very ground.

That emotion has no less direct an action in producing secretion than in causing spasm, is plain enough. Some criminals have cried that their judges may be affected, having, as many persons have, the power of "crying at will." A strong emotion raised by desire acts similarly to that which comes in spite of us, and cannot be subdued. It is not directly by the will, but through emotion, as Dr. Carpenter observes, that the lachrymal secretion is really excited; and I know from experiment that this is true.(a) In the same manner, we can act on the heart's action, not voluntarily, but by exciting some strong feeling or other of the mind. Idiots, imbecile and weak persons, are proverbially given to tears, and they are also peculiarly prone to involuntary muscular action; and the emotion of dreams has peculiar power, not only over the secretions, but the muscles also, for the will interferes not with it. Effects of the influence of true emotion we see every day; states of the salivary, mammary, menstrual, hepatic, and renal secretions, are no equivocal witnesses of its power; and, certainly, the reparation of accidents and operations is much influenced by the mind, and, I think, directly; if the secretory processes be thus affected by it, why should not those of nutrition and repair? The effects of mental attention on the bodily organs have been treated of expressly by Dr. Holland;(b) but, with regard to some of these, it is hard to say that they are really consequences of *pure* attention. However this be, *attention* fixed on organs diseased or disturbed in function, has often the worst influence. At the time the physician would have the heart of a patient equally beating, it is frequently thrown into irregular and violent action by the mere circumstance of the *attention*, unassociated, it may be, with *conscious* emotion, being fixed upon it; and it has often struck me, that profound sleep would be the best time for ascertaining some conditions of the organ.

Lallemand, Rostan, and other writers, count grief among the causes of ramollissement; and it is very easy to conceive a part already weak in power of assimilation, and just able to maintain its life, perishing quickly from that general weakening of the vital functions which sorrow or over-occupation may produce; or "from the disturbance of the nervous force indirectly interfering with the process of nutrition, inasmuch as this force exercises always some influence on the nutrition of each part, and is (as one may say) one among the plasturgic forces."(c)

Occupation, as well as emotion of mind, must be considered in reference to atrophy and its results. That the nutrition of the brain and other organs may be most seriously impaired by over-study is beyond question. But most employments of the mind imply emotion, though it more predominate in some cases than others; the school of arithmetic and the world of politics act, of course, very differently. Dr. Forbes Winslow has written a monograph on "softening of the brain arising from anxiety and undue mental exercise;" and there can be no doubt that, in many instances, threatened softening is only to be averted by an instant retreat from the toils of business, from anxiety I dare not say, for from this there is, too frequently, no refuge. But many cases of incipient ramollissement have been mistreated by everything that favours atrophy,—by low diet, blood-letting, and unsparing mercurials,—and so nature, already exhausted to the utmost, has been exhausted more.(a)

The instances referred to are those happening at a late period,—instances, some of them, of pure degeneration or local death. But there is no season, save that of infancy and the dawn of childhood, which is secure from the atrophy of mental toil, the excess of which has often, no doubt, hastened death greatly. Southey, speaking of Kirke White, plainly says: "Cambridge finished him." "Peace has her victories no less than war," and, like war, she has her deaths also. Pale students pine in miserable garrets, and die of atrophy. But the saddest of all the instances of defective nourishment, and the ills it leads to, is that produced in earliest youth, or childhood even, by, what is termed courteously, "education." To hear a pale, languid, spiritless boy recite long passages from Virgil, with a tone of monotony never relieved, and an emphasis ever in the wrong place, can only give pleasure to those of his mistaken relatives or friends who seem to think that it takes not less genius to remember the Æneid than it did to compose it.

As to the mischief of attempting to "force" the intelligence, much as plants are forced often in hot-beds, I may well cite the high authority of Dr. Holland. "We find, in Quintilian, a writer ever of sound and enlightened judgment, many valuable precepts as to the cultivation of memory, and an earnest reprehension of attempts at a premature development of this or other faculties. The phrase he applies to such precocious growths, 'Inanibus aristis ante messem flavescunt,' has its exact counterpart in Lord Bacon's description of 'that over-early ripeness in years which fadeth betimes.'

"In the course of my practice I have seen some striking and melancholy instances of the exhaustion of the youthful mind by this over-exercise of its faculties. In two of these, unattended with paralytic affection, or other obvious bodily disorder than a certain sluggishness in the natural functions, the torpor of mind approached almost to imbecility. Yet here there had before been acute intellect with great sensibility; but these qualities forced by emulation into excess of exercise without due intervals of respite and with habitual deficiency of sleep."(b) Exercise is, no doubt, the power of the mind; but, when carried perpetually to the pitch of exhaustion, the brain may become damaged, perhaps irreparably, and the mediocrity of manhood forms a painful contrast with the brilliancy of youth, and the decline of the faculties comes long before its time.

(a) See Dr. Carpenter's article "Secretion," in Dr. Todd's "Cyclopædia." That many diseases become extraordinarily aggravated by conditions of the mind, has been long known to our greatest observers. Sydenham, speaking of the treatment of gout, observes: "Quinimo animi tranquillitas omni ope stabilienda est," etc.—Opera Omnia. Edition of Sydenham Society, p. 439. The proneness to infection produced by fear and anxiety also bears upon this question of the effects of nervous influence on nutrition.

ON THE RECENT DEATH FROM CHLOROFORM.

By J. CHITTY CLENDON, Esq., M.R.C.S.
Surgeon-Dentist to the Westminster Hospital.

Death from chloroform, and in the presence, too, of distinguished surgeons, is an event which cannot fail to shake the confidence of the Profession and the public in this important anæsthetic agent, and to induce much hesitation on

(a) Dr. Quain observed, in the discussion which followed the reading of this paper, that "the relation of the mind to the disease of the heart in question (fatty degeneration) was one of great interest. It had happened to him to have met with several cases of degeneration of this organ in individuals who had suffered much mental anxiety. In three cases the degeneration was such as to have led to rupture of the heart; such individuals may be said literally to have died of a broken heart." Emotion may, by frequently disturbing this organ when degenerated, add greatly to the exhaustion of its action, and yet more lower its nutrition, and all to its degeneration correspondingly. Again, the heart, enfeebled by degeneration, impairs the nutrition of the body generally, and the latter re-acts upon it; and, however simple the process of decay, the complexity of its causes is often extreme.

(b) "Chapters in Mental Physiology," p. 138.

the part of those who daily administer it. It seems, therefore, the duty of all whose attention has been directed to the subject, to put forward, for the consideration of themselves and their brethren, any observations which their experience may suggest as to the course most proper to be adopted on a question of so much moment.

A great majority of the cases hitherto reported as fatal, have occurred on the Continent, or in the provinces; few, if any, have come under our own observation; and, while opponents have not failed to ascribe death, in each recorded instance, to chloroform, its advocates, on the other hand, have invariably attributed it to some latent organic disease; to want of tact and experience on the part of the practitioner; to the impurity of the chloroform, or to some error in the mode of administering it. From the clear and circumstantial account furnished, the present case seems to admit of none of these objections, for the patient had, a few days previously, been under its influence for a lengthened period without suffering the least inconvenience. Exactly the same chloroform was used on the second occasion as on the first, and the gentleman who administered it had had considerable experience in its use. The partial success which attended the several efforts to restore animation, would also tend to the belief that death resulted from functional disturbance, not from a morbid condition of any vital organ. Taking, therefore, the case as reported, without knowing what a *post-mortem* examination may reveal, I think there can be no doubt that death, in this instance, was attributable to chloroform.

Now, if we admit that death *may* occur from chloroform, in a case where every care and precaution are taken, and where the patient is, to all appearance, healthy, it becomes a most important question, Are we justified in using it at all? This, it appears to me, is a point on which some authoritative decision should, if possible, be obtained, and which ought not to be left to individual will or individual responsibility.

Some two or three years since, a death, supposed to be from chloroform, occurred at Boulogne, on which the French Government immediately instituted a medical inquiry; but in this country we cannot expect Government interference, nor, consequently, any decision having the force of law. Yet, I think, if a Committee could be formed of leading members of the Profession, to examine into and maturely weigh all the evidence for and against chloroform, the propriety of continuing its use, and the safest manner of using it, the deliberate opinion of such a body must have great weight with all classes of the community, would greatly reassure the individual practitioner, and could hardly fail to lead, in many instances, to an improved method of administering it. To select unbiassed judges might seem a work of some difficulty; yet, I think, such a Committee might be formed, of gentlemen already in office by the choice of their medical brethren, namely, the Presidents of the several Medical Colleges and Societies, in the Metropolis, while, against the impartiality of a body so constituted, none could take exception. But, in the interim, or until something like uniformity in opinion and practice can be arrived at, one other question is of paramount importance for us all to consider, namely, by what method of administering, and by what indications during the process, can the safety of the patient be best insured, while we continue to mitigate suffering by this powerful agency?

On both these points I wish to offer a few remarks; for, as I have given much attention to the subject, and had considerable experience in the use of chloroform ever since its introduction, I feel it my duty to state the conclusions I have arrived at, and I trust I shall be pardoned if, at the commencement, I refer to a pamphlet(a) I published three years ago, and again earnestly call attention to the following quotations:—

"I usually administer it on sponge, placed on a small plated mask, with flexible edges, made by Messrs. Fergusson, the surgical instrument makers, near St. Bartholomew's Hospital. This little apparatus is cleanly and convenient for covering the mouth and nose; not being complicated with valves, it cannot get out of order, and it is perfectly easy to breathe through."(b)

"... I very much prefer this mode (the mask) to the napkin or handkerchief; patients complain of the latter producing a sensation of suffocation. The chloroform, too, is spread over a large surface, and when folded up cannot be so conveniently directed, nor kept so much under control. The mask I entrust to patients to hold for themselves; if they find the vapour too strong at first, they can remove it, and accustom themselves to it gradually."

Now, as to the best method of administering it. I am aware there are many practitioners whose opinions are deserving of respect, who still advocate the use of the napkin or handkerchief, and as far as I can ascertain, on the ground of its being the simplest mode, and the one always adopted in Edinburgh. But I doubt if it be the simplest mode; it certainly appears an unphilosophical one. A comparatively large and unmeasured quantity of chloroform is poured on a folded handkerchief, which quickly spreads over the greater part of its surface. As respiration could not be carried on through the handkerchief, it is held at a little distance from the mouth; the chloroform must, therefore, evaporate, and mingle with the surrounding air before it can be inhaled. Besides the waste this occasions—an ounce being used when a drachm would suffice—there are no means of knowing how much of the vapour the patient is inhaling; that will depend in a great measure on the nearness of its approach to the mouth. The handkerchief shuts out from view a considerable portion of the face, and during the critical part of an operation, or when an operation possesses more than usual interest, there is a risk of the attention being withdrawn from the chloroform, and by the handkerchief being inadvertently allowed to press on the mouth and nostrils—of excluding air altogether.

Another great objection to the use of the handkerchief I shall have occasion to refer to presently; but I think those already mentioned quite sufficient to counterbalance any advantage to be gained from its simplicity.

Masks of various forms, for covering the nose and mouth, fitted with valves, are frequently employed. The object of the valves is, to prevent the breath returning through the sponge which holds the chloroform.

During inspiration a valve opens, to admit air impregnated with chloroform; it then closes, and the expired vapour escapes through a second valve, the two opening and shutting alternately. This plan is cleanly and economical, inasmuch as it prevents a wasteful discharge of vapour into the apartment. Its great drawback is, the liability of the valves to get out of order, or to be impeded in their action; more especially when respiration becomes feeble, or when the patient inhales in a reclined or recumbent posture, the valves, which are arranged to act vertically, being then placed in a horizontal position. Under such circumstances, it is evident the requisite supply of air may be diminished or entirely cut off. I have seen this happen on more than one occasion, when, but for the warning afforded by the suffused state of the countenance, and the purple hue of the lips, the patient would have been suffocated.

For these and other reasons, I prefer the simple mask before described, with a sponge just large enough to absorb a drachm and a-half of chloroform; this, as it cannot possibly offer any impediment to respiration, requires no attention, unless to renew the chloroform, during the process of inhalation. I always allow patients to apply it themselves, as long as the power of holding it remains; by inhaling for a few moments and removing it at pleasure, they gradually become accustomed to the vapour, and confidence is gained. When these attempts have been renewed three or four times, the chloroform begins to take effect, and tranquillity is insured; struggling, so painful to witness, and the consequent necessity for coercion, are thereby avoided. Relieved from all anxiety on this account, the practitioner is enabled to devote his undivided attention to the patient's respiration. To this end the throat and upper part of the chest should be divested of covering; and, from the commencement of inhalation until its termination, every respiration should be carefully noted; while the respiration is free, there cannot possibly be danger; the moment hesitation or embarrassment is perceived, the chloroform should be removed, and then, by compressing the chest, a single free inspiration will suffice to place the patient in safety. In experiments on domestic animals,

(a) "On the Use of Chloroform in Dental Surgery," Highley, Fleet-street, 1849.

(b) This is a point to which too much importance cannot be attached. Some of the fatal cases related, I fear, have arisen from the folds of the napkin being too thick, or from valves and stoppers becoming fixed, and thus preventing the admission of the necessary supply of air. Those who administer anæsthesia should carefully watch the patient's breathing. The latter affords a far better indication than the state of the pulse, the heart's action, or the condition of the pupil, all of which will be found to vary in different individuals."

I have invariably found, however feeble respiration had become, if the chloroform were removed, and the animal exposed to the air, it quickly recovered; but when, on the other hand, breathing had entirely ceased—although no time were lost—neither artificial respiration, opening the jugular vein, nor any means I could employ, succeeded in restoring it; and I am, moreover, informed by a gentleman who has repeatedly tried galvanism and electricity with the same object, that his attempts were equally unsuccessful.

When the handkerchief is used, continued attention is required to hold it in the proper position, and then it obscures so much of the face and neck that it is difficult to watch the indication I have spoken of. In such cases the state of the pupil is occasionally noticed, and the pulse from time to time referred to; but while the former is an uncertain, the latter may prove an unsafe guide, and ought never alone to be depended on. At times, and under the same circumstances, we find the pupil contracted, at others dilated, its condition seeming to depend on the temperament of the patient. During the early stage of inhalation, the heart generally beats quickly, and often tumultuously; yet I have known a pulse at 140—perhaps from the excitement of entering the operating theatre—gradually drop down to 100, under the influence of chloroform; and I believe physiologists are agreed, that the heart's action may continue a minute or longer after respiration has entirely ceased.

In the recent fatal case, the failure of the pulse appears to have afforded the first indication of danger; how long the patient had then ceased to breathe is not stated, and probably is not known. But, whatever the period, the attempts to promote respiration were partially successful, and,—although dangerous to push the chloroform so far,—had the failure been detected on the instant, is it unfair to believe the result would have been different?

I would, therefore, again most emphatically repeat, *watch the breathing*. It is now more than three years since I pointed to this as an unerring guide; subsequent daily experience has tended to confirm the opinion I then expressed; and I can conscientiously declare, in the numerous instances in which it has fallen to my lot to administer it, I have never witnessed symptoms which caused me a moment's uneasiness; nor have I heard of subsequent effects more formidable than sickness and depression.

A few words as to the quality of chloroform. I have obtained it from many sources, and to the credit of chemists be it said, with one exception, have found it pure. In the instance referred to, it was supplied by a wholesale druggist to a public institution; the odour was peculiar, and it left on the sponge a most offensive residuum. But, however pure and carefully prepared, chloroform is liable to decomposition. On one occasion, in replenishing a bottle in daily use from a larger supply kept in a cool cellar, I noticed a vapour resembling the fumes of nitrous acid, arising from the neck of the bottle: its effect on the nose was highly irritating, and, in that condition, could not have been inhaled for an instant: in a less advanced stage it might have been administered, and produced unpleasant consequences. On referring to the chemist, from whom it was obtained, he admitted he knew of similar instances; it arose from a sudden decomposition, the causes of which he could not explain. This shows the necessity for watchfulness, taking nothing for granted. When we have satisfied ourselves that each step in the process has been carefully attended to, we need have little fear for the results.

Albemarle-street.

Medical Times & Gazette.

SATURDAY, JUNE 12.

THE INQUEST AT NORTH WALSHAM.

A case in which the medical skill of an homœopath, Dr. Bell, of Norwich, has not been displayed to advantage, has lately attracted much attention in Norfolk. An inquest was held at North Walsham on the body of the patient, who died from abscess of the kidney, brought on, in the opinion of the jury, by "improper treatment." The facts of the case are simple enough. A so-called charitable lady, who, like many Ladies Bountiful, is gifted with a hankering after novelties, took a poor man, supposed to be suffering from stone, from under the care of his surgeon, and sent him to Norwich, to be attended by Dr. Bell. The homœopath unwisely quitted his globules, and betook himself to the catheter. More force was used than should have been, and the consequence was, that a false passage was made, or such irritation was created, that inflammation of the bladder and abscess in the testicle followed, the patient's health gave way, and he finally sunk with abscess in the kidney.

It is with extreme regret that we observe a regular practitioner, Mr. Webber, is mixed up in the business, by having met Dr. Bell, and assisted him in passing the catheter into the bladder. He has been bitterly punished for his infringement of what should be a binding professional rule. Dr. Bell attempted to shift the blame of the case from his own shoulders to Mr. Webber's, and with such success, that the jury, although they decided that the deceased had been improperly treated, declined to specify by whom! It must have been either by Dr. Bell or Mr. Webber, and whoever reads the case, will have no hesitation in fixing on the culprit; and the ambiguous verdict of the jury has left a slur on Mr. Webber, which is a kind of poetical justice for the sin of keeping indifferent company.

Perhaps nothing is more distasteful to us than the way in which Dr. Bell, by his own showing, treated Mr. Coleby, the surgeon who first attended the case. Mr. Coleby had diagnosed stone in the bladder, had informed the man of the fact, and suggested an operation. Before this could be done, the man was carried off to Dr. Bell. Dr. Bell, after the mild practice with the catheter before referred to, writes to the Fair believer in homœopathy, "that he had examined the man, who was in a deplorable state (!); that he had a small stone in his bladder, and had evidently been under a dangerous affection since last harvest; that she could adopt one of three courses:—She could place him under the care of Mr. Coleby again, *and, when his attention was more immediately directed to the case, perhaps he would be more fortunate in detecting the nature of the complaint;*" or she could send him to the Norwich Hospital, or into lodgings, to be treated by himself.

This was about the coolest thing of all. The way in which the homœopath assumes credit to himself for pointing out the case, and hopes his erring predecessor may be "more fortunate" in the diagnosis when his opinion is known,—and thus attempts to damnify Mr. Coleby in the eyes of a lady who may, probably, have been that gentleman's patient before she turned homœopath,—is one of those nice little bits of diplomacy which, we trust, are practised only by the ingenuous disciples of Hahnemann.

THE CASE OF MR. PASCOE.

We had confidently hoped, as already intimated to our Correspondents, that the unjust sentence passed on Mr. Pascoe would be reversed. We deeply regret to find that we were mistaken. The following letter has been addressed to the Editor of this Journal; and we understand that a similar communication has been sent to other gentlemen who have communicated with the Secretary of State concerning this unfortunate man:—

"Sir,—Mr. Secretary Walpole having carefully considered your application in behalf of William H. Pascoe, I am directed to express to you his regret that there is no sufficient ground to justify him,

consistently with his public duty, in advising Her Majesty to comply with the prayer thereof.

"I am, Sir, your most obedient, humble servant,
(Signed) "W. Waddington."

With this answer we cannot, however, rest satisfied. We have had apparently the whole evidence before us on which Mr. Pascoe was condemned. We found—and our opinion was confirmed by able lawyers—that the medical evidence given on the trial was that which condemned Mr. Pascoe. We asserted without hesitation, that this evidence was erroneous; and the Profession has unanimously agreed in this opinion. We have a right to know on what additional evidence Mr. Walpole grounds his unfavourable opinion. We have been informed, that Mr. Pascoe is not a man of respectable character. This is, however, nothing to the purpose. The real question is, whether the administration of savine is sufficient evidence that the production of abortion is contemplated. This is a question which concerns, not Mr. Pascoe alone, but every man who employs this or any other powerful drug. If Mr. Pascoe's trial is to be a precedent, no man is safe. With all our force we protest against it; and we proclaim it to be a trial in which present injustice has been done to the individual, and by which future injury may be inflicted on the Profession.

Mr. Walpole has "carefully considered" the case. We are bound to accept this statement; but we only claim what is due to our position, when we demand to know the additional evidence, if there be any, which has led Mr. Walpole to sanction the verdict of the jury. We have taken this case up solely on the grounds of justice and right. We knew nothing of Mr. Pascoe, and now know nothing of him, except what vague rumour has told us. Having formed our opinion without prejudice, we cannot rest content with a short and unsatisfactory formal official note.

We entreat Mr. Walpole, unless he wishes to leave a most unfavourable impression on the mind of every member of our Profession, to allow the evidence to be laid before some eminent physician. For example, if Sir James Clark, or Dr. Holland, or Dr. Watson, or Dr. Forbes, be allowed to know the grounds for Mr. Walpole's opinion, and if they affirm the correctness of these grounds, we, and, we think, the body of the Profession generally, will be satisfied. But if this favour be not accorded us, we cannot do otherwise than deem that a deep and crying injustice has been committed, and that an innocent man has been sent to undergo, among the most miserable outcasts of the human race, the penalty of transportation—the victim of professional ignorance and official inertia.

THE MILITARY ORDER OF THE BATH AND THE MEDICAL PROFESSION.

We publish below the addresses signed by two hundred and twenty-two Medical officers now serving in the Bengal army, and presented on their behalf by Mr. Ranald Martin to General Sir Howard Douglas and Lieutenant-General Sir De Lacy Evans. They are testimonies of gratitude to those gallant soldiers for their able advocacy in Parliament of the rights of Medical officers to the Military Order of the Bath. To the persevering efforts of those gentlemen in the Senate, and to their representations to the late Ministry, the Profession mainly owes its eligibility to a justly coveted honour in the gift of the Crown. The difficulty with which this Order was wrung from the professional advisers of Her Majesty must only enhance the value of the services of those who, in season and out of season, so earnestly contended for the full rights of the Medical Profession, and would be contented with no less. It was in vain that those who opposed the grant of the *Military* Order of the Bath to Medical men contended, that as they shared no common danger with the soldier in the field, they had no right to claim with him a common honour; it was in vain this language was used, when the generous testimony of these two gallant soldiers, who have witnessed many a well-fought field, utterly belied such a statement, and afforded proof that the military surgeon was often obliged to be in the very thick of the fight.

To the truth of this testimony, Dr. Davidson, of the 43rd Regiment, has unhappily set the seal of his blood in a late engagement with the Caffres; and that the Naval Surgeon is equally exposed, we appeal with pride to the taking of Largos, where Assistant-Surgeon Sproule was seen stepping from boat to boat, rendering assistance to the wounded, under the murderous fire of the enemy's fort,—the same gentleman who has since been severely wounded at the taking of Rangoon. Of the justice of the claim of Medical officers to the title of C.B., the more liberal-minded members of the two services never entertained a doubt; and recent occurrences, so honourable to their devotion and courage, must now convince all, that the favours of the Crown have only been properly extended to them.

Now, however, that the fight is done, we should be the last to forget those who bore the heat and burthen of the day. The grateful votes of thanks, made by *two hundred and twenty-two* military surgeons in the Bengal Presidency, must be indeed pleasing to the gallant soldiers who are the recipients of the testimonials. There is one other gentleman, however, to whom, as much as to them, the thanks of the entire Profession are due. Sir De Lacy Evans, in acknowledging the receipt of the address to Mr. Martin, begs him to inform those who signed it, "that it was their former comrade and brother officer who exclusively prompted me to move in this matter, who furnished me with the principal facts connected with it, and to whom is, therefore, chiefly attributable the result." This graceful acknowledgment of the services of Mr. Martin is only what he was justly entitled to; and we are sure we speak with the general voice of the Profession when we say, that he who did so much to throw open to medical men so honourable a distinction of the Crown, is well worthy to be one of its first recipients.

"TO GENERAL SIR HOWARD DOUGLAS, BART., G.C.B.

"The undersigned officers of Her Majesty's and the Honourable Company's Medical Staff serving throughout the territories of the Bengal Presidency, impressed with a deep sense of the obligation under which their class has been placed by your admirable Parliamentary assertion of their claims to honorary distinction from the Crown, beg to wait on you with an expression of their sincere thanks.

"You, honourable Sir, were the first who, within the walls of Parliament, made manifest the injustice of not extending a community of reward to a body of commissioned officers, sharing in the responsibilities, hardships, and dangers of their military brethren; and from no one could the exposition come with greater grace, or moral force, than from a commander of so much experience as yourself, who had such ample opportunities of judging the merits of the question, and whose eminently scientific acquirements conferred a lustre on his advocacy.

"Accept, then, Sir, the assurance of the high respect of the undersigned, and of their deep appreciation of the judicious and energetic manner in which you urged the expediency, no less than the justice, of claims which have at length obtained the recognition of their gracious Sovereign.

"That many years of prosperity and happiness may be added to your truly distinguished, valuable, and dignified life, is the cordial aspiration of those who have the honour to subscribe this humble testimonial of grateful esteem."

[Signed by 222 medical officers.]

"TO LIEUTENANT-GENERAL SIR DE LACY EVANS, K.C.B., ETC., ETC.

"The undersigned Medical Officers of Her Majesty's and the Honourable Company's Army, serving at the Presidency of Bengal, entertaining a sincerely grateful sense of the able and generous manner in which, as a Member of the Senate, you have stood forward to press the claims of their class to marks of honorary distinction on the part of the State, do themselves the honour of tendering you their warmest thanks.

"Following up the exertions of their illustrious advocate, General Sir Howard Douglas, you, honourable Sir, have brought masculine powers of reasoning to bear upon the general subject; while your personal experience in the East, as well as in Europe, gave weighty cogency to the whole,—paving the way to a result by which medical officers share in those marks of national honour so precious to the worthy and the brave.

"With a deep sense of your sympathy and services in their cause, the undersigned beg of you to accept of their cordial best wishes for your health and prosperity."

[Signed by 222 medical officers.]

"Green-street, May 29, 1852.

"Dear Sir,—I receive with the highest satisfaction the address which you have done me the honour to present from the officers of Her Majesty's and the Honourable East India Company's medical staff, whose names are appended to that very gratifying document.

"Ever present and attentive in my place in Parliament when any measure affecting the military affairs of the country might be brought into discussion, and never neglectful of any opportunity of acting to the best of my judgment in the manner I thought most conducive to the good of the service, the advantages of the members, and the general bearing of its usages and regulations, I could not fail to perceive, in the case to which this address relates, an occasion on which I might be of some use in exhibiting, and perhaps rectifying, an act of injustice in not extending a community of honorary rewards to the officers of the Medical Staff, who share with their military brethren in all the responsibilities, hardships, and dangers of actual service.

"If I was prompt to undertake this, it was because I felt the case was strong in its justice; if energetic, it was because I deeply felt the wrong; and if I have contributed in any degree to remove the disability, this address is the highest reward a public man, and ho a general officer, can receive.

"I request you will do me the honour to communicate this my acceptance of the address to Sir James Thompson, K.C.B., and any others of the Committee for whom you act; and, in doing so, to request them to receive, individually, the thanks which are due collectively to the body from which the address emanates.

"I have the honour to be, dear Sir,

"Your very faithful and sincere

"HOWARD DOUGLAS.

"To James Ranald Martin, Esq., F.R.S."

"London, May 30, 1852.

"My dear Sir,—Since you have been kind enough to be the medium of conveying to me the address of the Medical Officers of Her Majesty's and the Company's Army in Bengal, I trust you will excuse my requesting your kind offices also in conveying to Sir James Thompson, K.C.B., and the other officers who have signed this address, my high appreciation of the complimentary expressions it contains; and I shall be glad if you will also inform them from me of the fact, though you perhaps may be reluctant to do so, that it was you, their former comrade and brother officer, who exclusively prompted me to move in this matter, who furnished we with the principal facts connected with it, and to whom is, therefore, chiefly attributed the result.

"I have the honour to remain, dear Sir,

"Yours very faithfully and sincerely,

"DE LACY EVANS, Lieut.-General.

"To J. R. Martin, Esq., Grosvenor-street."

THE HOME-MADEIRA AT TORQUAY.

DURING the year 1850, a noble-hearted lady, while temporarily residing at Torquay, conceived the notion of establishing a small asylum for poor patients whose maladies, although of a decidedly phthisical nature, were still not so hopeless but that they might derive great benefit from the delightful temperature of this watering place during the trying winter and autumn months. The rich have long taken advantage of the delicious climate of this and neighbouring watering places, protected as they are by the bold sweep of the southern coast from wintry winds, and rendered humid and soft by the luxuriance of vegetative life almost throughout the year. Why should not the suffering poor also participate in those advantages which Providence intended for all alike?—was the question which this benevolent worker evidently asked herself; and the reply made, was the earnest manner in which she set about removing the difficulties which lay in her way; for by the second season the little hospital was established, with fourteen in-patients, all of whom have gone on well. The plan on which this humane establishment is founded is so excellent, that we wish it all possible success, and shall support it to the best of our power. It is intended to form the Home Madeira, if we might so term it, of the contiguous counties of Berks, Dorset, Gloucester, Somerset, and Wilts, from the large towns of all of which it is readily accessible by railway. It is intended as a shield against the inclemency of those months in the year which are particularly obnoxious to poor patients suffering with chest complaints; opening on the 1st of October, and closing on the 1st of June; and, lastly, it is intended to be in some degree self-supporting. No medical man can doubt the advantages to be gained, by even decidedly phthisical patients, from a pure warm air, a regulated diet, and medical superintendence. That they are capable, when properly combined, of warding off, for years, the dread ripening of miliary tubercles, no one, especially since the establishment of the Brompton Hospital, can deny. There is something in the sea air—the presence, perhaps, of iodine—which renders it peculiarly adapted for such cases; and we shall look upon the establishment of sea-side hospitals, so situated as to form the centres of large districts, as powerful auxiliaries in the treatment of the incipient form of a scourge which has been but too faithfully called "the English Death."

The self-supporting principle, which has been partially adopted at this establishment, is also excellent. Those who can, ought to contribute towards their support in every hospital. To all honest persons with a particle of independent spirit in their composition, it must be somewhat unpleasant to be the recipients of charity in any form. Again, all experience tells us, that that which is paid for is more highly valued than that which is obtained for nothing. Those persons who are in the receipt of weekly allowances, from benefit-clubs, etc., are expected to hand over a certain amount for their maintenance whilst in the hospital; and any person is allowed to claim all the advantages of the establishment for 10s. a week. This is as it should be. Those who enter the hospital, of course, anticipate a residence there during many months of the year; the charge of every individual case is, therefore, considerably higher than it averages in any other hospital, and its means of doing good would be considerably limited if it had to depend entirely upon the contributions of the charitable for support. Many of the poor persons, we understand, nearly maintain themselves by needlework in this establishment; and it seems to us, that employment of this kind might be adopted in a more systematic manner than it is at present in hospitals which treat mild and incipient cases, such as that at Torquay. The very employment would break that drear monotony of the wards which so depresses patients. The inmates of the Blind Asylum at Bristol produce a very considerable income by their industry and ingenuity, in fancy basket-working, etc., and we see no reason why the patients in the Torquay Hospital might not do the like, as

a market for such labours, at a high price, is always obtainable in charitable England. This suggestion is, however, for after-consideration. The aid of the charitable is at present imperatively called for towards building a permanent hospital, the present house not being calculated for its purposes. Towards this object, the lady-founder has already 600*l.* in hand, and 1000*l.* more is required. Who will help in this really good work? "Incipient cancer," we have already proved to be "a delusion and a snare;" but incipient phthisis no one denies; and a subscriber might have it in his power, by a very small donation yearly, of saving or prolonging many valuable lives.

THE BRITISH MEDICAL FUND.

We have great pleasure in complying with the request that has been made to us, to give the following Document a place in our pages. Its contents are calculated to call forth feelings at once cordial and melancholy. On the one hand, it presents the picture of a body of liberal-minded and noble-hearted men, devoting themselves with the utmost zeal to excogitate and establish an admirable institution for the good of their brethren, without other fee or reward than their own consciousness of doing good; and on the other, those brethren, or the majority of them, sitting by in thoughtless apathy, regardless alike of the boon itself and of the labours of those who are proposing it for their acceptance. It is truly humiliating to reflect, that while every vulgar trade, studious of self-respect and spurning mere charity, has got its benefit society, its bank of independence, to enable its members to meet all the sadder contingencies of life—sickness, old age, widowhood, orphanage, and death itself—by the simple and facile process of deducting a pittance from their earnings in the day of youth, health, and prosperity, while the Medical Profession alone has disdained such a noble resource, and set itself down contentedly to suffer, or to eat the ignominious bread of charity for relief. Nay, it appears from the authentic document we publish, that the members of the Profession have, as a body, not only neglected until now to provide for themselves such a stay in trouble; but that they have actually rejected it when raised by the gratuitous labours of a few noble volunteers, and presented to them in a matured and practical form, with the humble request that they would condescend to help themselves, by taking advantage of its admirable provisions!

Nevertheless, although it is clear that the Directors of the British Medical Fund could not, under actual circumstances, have come to any other conclusion than that recorded in their Report, we can hardly yet be brought to entertain it even as a possibility, that the Profession will allow so admirable an Institution to become extinct,—at least without making one effort more to save it. After the almost unexampled labours of the Directors, thus so sadly requited, it would hardly be reasonable to expect that they should enter on a new career of exertion, even in the same good cause; but we cannot, for a moment, doubt that, should the Profession at large call upon them, the same sentiments which have hitherto led them to devote so much of their valuable time and intellectual power to it, will still induce them to lend their aid in carrying on the great experiment, if not by their own personal co-operation, at least by their counsel and advice, and by the communication of all the practical knowledge which their long experience has enabled them to accumulate. Notwithstanding the past apathy of the members of the Profession generally, in regard to their best interests, we still are willing to believe that, if the great experiment could be carried on for a few years longer, to afford time for fuller consideration and reflection, they would yet awake from their lethargy in sufficient numbers to enable it to be conducted to a successful issue. Judging from some statements in the Report, we should imagine that, if the sum of 2000*l.* could be at once subscribed, it would be sufficient to accomplish the great end in view. TWO THOUSAND POUNDS!

> "Shall it, for shame, be spoken in these days,
> Or fill up chronicles in time to come,"—

that all the independent spirit, and all the well-earned gains of the whole Medical Profession in England, were inadequate to the production of such a paltry sum for such a noble purpose? *O Dii immortales avertite et detestamini quæso hoc omen!*

REPORT OF THE DIRECTORS,

READ AT A MEETING OF THE MEMBERS OF THE BRITISH MEDICAL FUND, HELD JUNE 2, 1852. JOHN FORBES, M.D., F.R.S., IN THE CHAIR.

Gentlemen,—You have been made aware, by the circular which you have no doubt all received, of the purpose of the Directors in calling the present meeting. If this announcement has excited in your minds some surprise as well as regret, it is hardly necessary to say how much keener these feelings must be in the minds of those who, for the last two years and! a-half, have been devoting themselves to the formation and establishment of the Society, and who entered on their task of framing it with the utmost confidence of being able to bring it to a prosperous issue.

Deeply impressed with the necessity of such an institution, and thoroughly satisfied that the form which they had given to it was admirably calculated to meet and remove many of the more pressing evils that beset the path of their medical brethren, the Directors worked zealously on; for a long time never doubting that their labours would be eventually crowned with success, and that they should thus be the happy means of conferring an inestimable benefit on the Profession. Having, however, at length, ascertained that the members of the Profession are not, as a body, sufficiently awake to the importance of the undertaking, or sufficiently alive to their own interests, to give it the support it requires, the Directors are reluctantly compelled to take the only course left open to them as conscientious administrators, and resign into your hands the offices they hold, and the management of the affairs connected therewith.

It is now some time since the Directors began to entertain doubts as to the eventual success of the Society; but, naturally unwilling to take any step that could tend to interfere, in any way, with its possible progress, or preclude the accession of that more general support and patronage which they still fondly hoped might be extended to it, they persevered in their original determination, leaving no means untried that appeared to them calculated to promote the interests of the Society, or which was attainable by the resources placed at their disposal. The interests involved in the undertaking were much too precious in their eyes, as members of the Medical Profession, to allow them to do their work with indifference or negligence, much less to abandon it, while there yet existed any reasonable prospect of its being brought to a successful issue. They felt that, entrusted as they had been with the direction of a great experiment devised for the good of their brethren and themselves, they were bound not to interrupt it until it had been fairly and fully tried. A fair and full trial, they are warranted in saying, has now been made; and, although the result has been very different from what they desired, they have no alternative but to consider their work as completed, and their exertions at an end. It will be for you to determine, whether the attempt should be renewed, under other management, and with or without some modification of the plan.

In resigning their trust into your hands, the Directors think it right to give a brief report of their proceedings from the beginning.

The fund, as you all know, took its rise from a previous attempt by Mr. Daniell to establish a Society on a somewhat similar principle, viz., that of securing annuities to the subscribing members and their widows. In the course of four years, Mr. Daniell had obtained 182 subscribers, and had

received a considerable sum in donations, but had not succeeded in carrying out his object to any practical purpose. Finding it difficult to work such an institution in the country, and ascertaining that there were some practical defects in the original plan, Mr. Daniell at length resigned the direction of his Society, at a public meeting, held in London in October, 1849. On this occasion, a Committee was appointed to place the Institution on a new and more scientific basis, and to carry it out on such principles as might be at once sound and practical. As it was from the members of this Committee that the subsequent Direction was mainly formed, the Directors are enabled to speak of the proceedings of the Committee as of their own.

The first business of the Committee was to determine the general principles on which the future Society should be constituted, and the various objects it should embrace. To attain this end, no labour was spared by the Committee, either in studying the subjects themselves, or in seeking for advice and assistance elsewhere, from those best qualified to give it. In due time, the plan of the Institution which was finally adopted by the members was completed. You are all well acquainted with it.

While still proceeding with their task, the Committee, deeming it most important for the future success of the Institution, that every publicity should be given to its plan, and as wide a co-operation and patronage as possible of the members of the Profession secured, endeavoured to attain these objects by means of circulars, and every other practical form of advertisement. One of these preliminary steps was the formation of an extensive Provisional Committee from all branches of the Profession, and from all parts of the country, who might be able to aid the Managing Committee with their counsel, and to whom might be submitted the plan of the Society when matured.

In answer to their appeal, the Committee obtained the consent of about 300 gentlemen of the highest standing and influence in the Profession to have their names enrolled as a Provisional Committee; while many others, who, from various causes, declined to enrol their names, favoured the Managing Committee with letters expressive of their approval of the Society, and promising it future support. The members of the Provisional Committee were accordingly called together, at a public meeting, held at the Freemasons' Tavern on the 23rd of March, 1850. On this occasion, the Managing Committee gave a detailed report of their past proceedings, and submitted to the gentlemen present a minute outline of all that they contemplated as to the plan and future government of the Society; and the meeting not only sanctioned all the past proceedings of the Committee, but adopted every suggestion and proposition made to it without a dissentient voice. The Committee was re-appointed, with a request, that they would continue their labours, and, as speedily as possible, lay the whole plan, as sanctioned by the meeting, before the Profession at large.

Confirmed in their views by so favourable a judgment, and supported by so extensive and influential a co-operation of their brethren, the Committee proceeded in their task with increased confidence. In accordance with the recommendation of the meeting, they drew up a comprehensive statement of the whole plan and objects of the Society, with specimens of the tables constructed for them by Mr. Neison, and a list of gentlemen composing the Provisional Committee. This prospectus the Committee had printed, and transmitted by post to every legitimate member of the Profession in England and Wales whose address could be procured, with a request, that those gentlemen who approved of the projected Society should forward their names for enrolment as future members. This circular was received by the Profession with very general approval, if the Committee may judge from the tenor of the numerous communications received in reply, and, still more, by the numbers that announced their intention of taking an effective part in furthering the objects of the Society,—no less than 158 gentlemen having, shortly after, expressed their desire to join it, and 111 having actually paid their subscriptions as members.

The Committee having, at length, succeeded in completing all the arrangements to their satisfaction, called a meeting of the members, on the 31st July, 1850, to obtain their formal sanction to the plan of the Society, and to the Rules and Regulations prepared for its future governance. At this meeting, all the Committee's past proceedings were sanctioned and approved; the Rules, after discussion and some amendment, accepted; and the members of the Managing Committee elected as Directors for the ensuing year.

When, at the public meeting called by Mr. Daniell in November, 1849, the Managing Committee accepted the trust of framing a new Society on a broader and more practical basis, they were well aware, that pecuniary means must be provided to enable them to meet the expenses which were inevitable in such an undertaking. These means were provided by the funds still remaining in Mr. Daniell's hands, and which, to the amount of 123*l.* 0*s.* 8*d.*, were transferred into the hands of the Committee.

In the statement of the accounts subjoined to the present Report, it will be seen what the precise outlay incurred by the Committee was; it is here referred to chiefly for the purpose of remarking, that a large portion of the sum mentioned was necessarily expended in their operations previously to the absorption of the original Committee into the Board of Directors. At the public meeting of the members it was necessary, therefore, to settle in what way the future expenses of the Society should be met during the period that must necessarily elapse before the cost of management could be met by the profits of the commercial part of the undertaking. It was accordingly settled by the meeting that, until this period arrived, the expenses should be borne by the funds derived from the donations and annual and life subscriptions of the members, or by such part of them as might be required for the purpose. It was self-evident that, without such an arrangement, the Society could not have any chance of success, as the important experiment which all were eager to make could not even be set on foot on any other conditions. It was on these terms, consequently, that the Directors undertook the conduct of the Society; and they feel assured that the members, whose liberal contributions have enabled them to proceed so far, will never regret that they have, at so small a sacrifice, been the means of giving to the Profession, and particularly to its less affluent members, so splendid an opportunity of consulting their own best interests, and the interests of those who are nearest and dearest to them. That the Profession at large has failed to take advantage of such opportunities, must be a matter of deep regret to all; yet the Directors are consoled by the reflection, that they have spared no exertion to place this boon within the reach of all who might be in a position to need such assistance.

The Society being thus formally constituted and entrusted to their management, the Directors forthwith proceeded to take the steps that appeared necessary to enable it to effect its purposes, by engaging offices, by appointing a secretary and clerk, by getting it enrolled as a benefit Society, according to law, by providing all the requisite books and papers, and by organising plans for making it as extensively known as possible throughout the Profession. In addition to the ordinary mode of advertisement in the public prints, particularly in the medical journals, they set on foot an extensive personal canvass of the members of the Profession, both in town and country, which has been carried on, up to a recent period, to the utmost extent their limited funds could justify. For this service they were fortunate in finding in their Secretary, Mr. Hawtayne, a most competent and efficient officer, who not only discharged the duty entrusted to him with the utmost zeal and assiduity, but performed it with such cordiality, comity, and consideration, that nothing was left undone that was calculated to make his canvass successful. During the first and second year of the Society's existence, Mr. Hawtayne thus visited many of the principal towns in England, and the Directors feel bound to state, that a great portion of their success, imperfect as it has been, has been owing to his visits. It was mainly from the effects of these visits, as shown by a limited accession of members, and yet more by the almost unanimous expression of approbation of the plan of the Society, elicited at the public meetings called by the Secretary, that the Directors, in reporting their proceedings to the members at the end of the first year, were led to congratulate them on the satisfactory progress and prospects of the Society, though they could not conceal from themselves the disheartening fact, that the number of subscribing members, and still more of policy-holders, was considerably less than they had expected, and much less than they thought so admirable an Institution should have commanded. On this occasion, they could only report, that they had obtained 179 annual and life subscribers, and had issued but 23 policies in the Provident department. Feeling, however, that a

sufficient period had not elapsed to justify them in regarding the great experiment as yet sufficiently made, they consented to accept office for another year, encouraged by the cordial manner in which their past services had been recognised by the members, and not without hope, that the seed they had been so assiduously sowing, as Committeemen and Directors, during the preceding twenty months, might show corresponding fruit during the succeeding twelve. You have already been told that, in this hope the Directors have been disappointed; although they are conscious of no falling-off in their own personal exertions, or in the enforcement of means that seemed best calculated to insure success. Their system of communication and correspondence with the Profession has been continued; the amount of advertisement in the Medical Journals largely increased; and the visits made by the Secretary to the provinces more frequent and prolonged.

Having persevered in their endeavours for three quarters of the current year, the Directors felt it then necessary to investigate minutely the whole state of their affairs, in order that they might have time, before the Annual Meeting, to come to a determination as to what their future duty was in relation to their constituents. The result of this investigation was the conviction, that they ought no longer to delay calling the members together, in order that they might decide for themselves as to future proceedings. Without some great and speedy change in the prospects of the Society, the Directors felt, that it was impossible much longer to conduct it without running into debt; and, as they could perceive no evidence of such a happy change of prospects, they had no other choice but to resign into your hands the trust with which you have honoured them, and, with this, the future destiny of the Society.

A brief view of the recent progress and actual condition of the commercial part of the Society, as to its engagements and funds, will sufficiently prove to you that no other alternative was left to the Directors.

The total number of annual and life subscribers from the commencement has been 349: of this number, 68 have been added during the current year,—an addition, however, counterbalanced by the secession of at least an equal number of the old members; 79 having, up to the present date, failed to renew their subscriptions. This falling-off in the subscriptions would not alarm the Directors if they were enabled to state, that it was compensated by an equivalent increase of funds derived from policies. This, however, they regret to say, is by no means the case, as will appear from the following statement:—The total number of policies issued from the first, on which per centage could be made available, have been but 19; namely, 15 for life assurance, and 4 for deferred annuities: the total premiums on which amount to 115*l.* 13s. 9d., admitting of a deduction of only 11*l.* 11s. 5d. towards meeting the expenses of the Society.

It is true, that, in addition to these, 21 policies have been granted (conditionally) for provision during sickness, and 4 for reversionary annuities; but as these are subject to the restriction of the premiums being returned, in case a certain number of policy holders is not attained, no deduction could be made from them for the support of the Society.

And here it will be necessary to give some explanations respecting the proceedings of the Directors in regard to some of these policies.

It will be remembered, that the Society was advised not to undertake any responsibilities under the head of reversionary annuities until 250 subscribers for that form of annuities should have been obtained. The Directors, however, feeling the great advantages calculated to result to members from this branch of the Society, and desirous of bringing it into operation, proposed an arrangement with the Medical Invalid and General Life Office, by which that office undertook to hold itself responsible for all risks and liabilities, until the number of 250 should be completed, or until the Society should be in a position to redeem them. In adopting this course, the Directors felt they were consulting the best interests and security of the members in every way; first, by enabling them at once to avail themselves of these benefits at their present age, and while their health rendered them eligible; and, secondly, by guaranteeing the commercial security of their policies. The Directors, therefore, cannot feel otherwise than assured, that, in this arrangement, they shall have the entire sanction and approval of those gentlemen who have availed themselves of such provision for their families.

On the same ground, the Directors determined to issue policies for the Sickness Fund, subject to somewhat similar restrictions. They hoped, that a spirit of mutual encouragement among the Profession generally would be thus engendered, and that by that means the restrictions as to number might be more readily removed. Those gentlemen, however, who have taken out their policies for this particular fund, have done so on the understanding, that, should the required number of 200 subscribers not be obtained by the 1st of February, 1853, they will be at liberty to withdraw their premiums free of every deduction whatever.

The Directors have also made arrangements with the Medical Invalid and General Life Office, to relieve them of the liabilities already incurred on account of the policies they have issued for life assurance, until the 28th July, (the ordinary period fixed for the Annual General Meeting,) thereby securing the interests of the policy holders until the pleasure of the members now assembled shall be known with regard to the future mode of dealing with the Society.

The following are the heads of the pecuniary transactions of the Society from its commencement up to the present date; a detailed statement of which will be found in the auditor's Report now on the table:—

GENERAL STATEMENT OF ACCOUNTS,

From the 25th of December, 1849, to the 22nd of May, 1852, inclusive.

By amount of premiums invested	240	7	9
Premiums paid on reversionary annuity policies re-assured	65	1	11
Per centage on premiums transferred to Guarantee Fund	16	5	6
Balance in hand	16	7	4
	£338	2	6

If any part of the foregoing statement should convey the impression, that the expenses of conducting the Society have been large, the Directors feel assured, that such an impression can only arise from the comparative smallness of the receipts. Had these been such as the Directors were led to anticipate, a far different complexion would have

been given to such a statement. The Directors have no hesitation in expressing their conviction, that no Society, having similar pretensions, has ever been established for so small a sum as that hitherto expended on this.

It must also be borne in mind, that as many items under the head of "Preliminary Expenses" would not occur again, it might, consequently, be certainly expected, that the amount of subsequent expenditure would be considerably reduced below even the present amount.

It may, however, be estimated, that under the most economical management, a Society like this could not be conducted, as an independent Institution, under from 400*l.* to 500*l.* a-year. Now, to yield this amount, without encroaching at all on the sums subscribed for benevolent purposes, would require an annual income from premiums on policies, of at least 4000*l.*; whereas, the income at present arising from that source is only 270*l.* 0s. 6d. That the first-named amount of income is not larger than the Society might, with some confidence, have calculated on receiving, may be readily demonstrated, by taking a fair average on the transactions already effected with the Society. By this, it is shown, that 200 members subscribing to the Sickness Fund, would yield an income of 760*l.*; and 250 holding policies for reversionary annuities, a further sum of 4375*l.*, making a total of 5135*l.* It will thus be seen, that even so small a number as 450 members out of a community amounting, at least, to 15,000 or 16,000, would have afforded ample means for management, exclusive altogether of other resources; how much more than sufficient these means would have been, if, instead of 450 members, 1500 members, (certainly by no means an unreasonable estimate,) had joined the Society as policy holders, is self-evident.

The Directors have already expressed their extreme regret at having to announce to you such a consummation of their labours, and such a gloomy close of prospects that had opened with such brilliant promise. This regret they must long feel; but it will be lightened by the conviction, that they did their best to bring about a different issue, and that the object for which they were striving was at once admirable in itself, and of the highest importance to the Profession. They think that, in neglecting to avail themselves of the benefits offered by the Society, those gentlemen for whom its provisions were especially designed, have not only made a great mistake, but have committed a grievous wrong on their best interests; and the Directors believe, that when the means are no longer available, they will awake to a due appreciation of the greatness of the boon they have lost by their apathy and negligence. It is to be hoped that, if such a period arrives, the Profession may exert their powers to resuscitate this Institution, (they can hardly create a better;) and, learning wisdom from the past, may, by the supply of more timely and more copious nutriment, rear it to maturity and vigour. To continue the professional metaphor,—the Directors must declare, that the present decay of the Society is in no degree owing to any inherent constitutional defects, but is the result of inanition from external influences.

The Directors will only further add, that, though now formally resigning their offices into your hands, they are most ready to resume them for a time, if such be your wish, in order that the financial affairs of the Society may be finally wound up and brought to the best issue of which they are susceptible.

By order of the Board,
GEO. HAWTAYNE, Secretary.

The following resolutions were passed:—

Proposed by Dr. Peacock, seconded by Mr. Foster, and resolved:—

"That this meeting receives the Report now read; that it be printed and circulated among the members of the Society; and that it be brought under the notice of the Profession at large through the medium of the Medical journals."

Proposed by Dr. Jervis, seconded by Dr. Chowne, and resolved:—

"That, in accordance with the recommendation in the Report of the Directors, this Society be dissolved; and that the Directors be requested to take the necessary steps to wind up the affairs of the Society as speedily as possible, in accordance with the laws."

Proposed by Mr. Ince, seconded by Mr. Self, and resolved:—

"That this meeting accepts, with much regret, the resignation of the Directors, and requests them to continue their labours to wind up the affairs of the Society."

Proposed by Dr. Jervis, seconded by Dr. M'William, and resolved:—

"That this meeting offers its warmest thanks to the Directors for their unwearied exertions in behalf of this Institution, and regrets that their efforts have been so feebly seconded by the Profession as to render it necessary for them to discontinue their labours."

Resolved unanimously,—

"That the best thanks of this meeting be offered to Dr. Forbes for his very courteous conduct in the chair."

REVIEWS.

Chapters on Mental Physiology. By Henry Holland, M.D., F.R.S., etc., etc., etc. Founded chiefly on Chapters contained in "Medical Notes and Reflections," by the Same Author. 8vo. Pp. 301. London: Longman and Co. 1852.

Dr. Henry Holland has been long known to the Profession as a most able physician and accomplished scholar, one of whom its members were justly proud. He occupies the highest position in its ranks, and no one denies his right to it.

His present work consists of eleven chapters. Four of these chapters are now published for the first time. With reference to the remaining seven, Dr. Holland says:—

"Those who may have read my 'Medical Notes and Reflections' will, perhaps, recollect such chapters, as occurring in different parts of a volume chiefly devoted to subjects more strictly medical in character. Thus interposed, however, among the latter, they were deficient in the sequence and connexion naturally belonging to the topics they treat of, and which may be considered almost indispensable to a thorough understanding of the subject.

"This deficiency I have sought to supply in the present volume, by bringing these several chapters into one series, and by adding others which have appeared necessary to the completion of the plan."

The seven chapters, however, the names of which are derived from the author's previous work, have been entirely re-written, and very materially enlarged, so as to give to the whole work a certain unity, and to embody "the recent accessions of knowledge on numerous points having express relation to them."

Mesmerism and Homœopathy are touched on frequently in the course of his work by Dr. Holland; and the sound sense displayed in discussing these subjects, and the philosophical tone of his remarks on them, cannot fail to undeceive some of those men of learning and position who have been beguiled into lending the weight of their name for the spread of the dogmata of these *pseudo*-sciences.

The character of Dr. Holland's mind is stamped by his chapter on Medical Evidence:—

"There can be few better tests of a sound understanding than the right estimation of medical evidence; so various are the complexities it presents, so numerous the sources of error."

In the opinion expressed in this the opening sentence of this admirable chapter we heartily concur; and, of the extraordinary soundness of its author's understanding, after reading that chapter, none will doubt. To make an analysis of it would be impossible; it contains no superfluous word. Suffice it to say, that Dr. Holland looks to an advance in position of medicine as a science, "not by the addition of new facts only, but even more by new methods and instruments of research, and increasing exactness of details in every point of inquiry."

The second chapter is on the effects of mental attention on bodily organs. The chapter in the "Medical Notes and Reflections" bearing the same title occupies thirteen pages; this consists of thirty-three pages, and in it mesmerism and homœopathy receive some of Dr. Holland's hardest blows.

After speaking of the frequent struggle between the voluntary and the automatic parts of our nature, and of the singular impairment or loss of voluntary power, and change in other mental faculties from certain impressions on the sensorium, and alluding to the remarkable diversity in different temperaments, as respects their liability to these changes, Dr. Holland remarks, that it is the nervous or hysterical temperament that is the most prone to be acted upon by mesmeric influences.

"Applying these facts" (he continues) "to the more mysterious exhibitions of this influence, they cogently suggest the question, how it can happen that such manifestations of new and exalted power—the knowledge of events far distant in space and time—the instant recognition, without inquiry, of the seat and nature of internal disease, and of the befitting treatment—vision, or that perception which is equivalent to it, through other organs than the eyes, etc.—how it happens, I say, that faculties so marvellous should be given to those of feeble, vague, or distempered mind, and denied to men of the highest mental energy and intellectual powers?—given, moreover, by persons who themselves possess none of the faculties which they thus miraculously bestow?"

Dr. Holland then proceeds to illustrate the influence of attention, as an act of mind voluntary or involuntary, upon the bodily organs in a state of disease.

"To the cure of the dyspeptic I have already sufficiently alluded in illustration. Closely akin to this is the disorder of the hypochondriac, some of the most singular perversions of which admit of the same explanation. Here the patient, in fixing his consciousness with morbid intentness on different organs, creates not merely disordered sensations, but often, also, disordered actions in them. There may be palpitation of the heart, hurried or choked respiration, flatulence, and other distress of stomach, irritation of the bladder, vague neuralgic pains, all arising from this morbid direction of attention to the organs in question. It is certain that many of the secretions are immediately affected by emotions of the mind; and the same effects appear to arise from anxious and sustained attention to the parts concerned in these functions."

We regret that the space at our disposal prevents our following Dr. Holland through the whole of this chapter; but we trust that the majority of our readers will master it in full for themselves.

The chapters, or rather essays, now published for the first time are, On Mental Consciousness, in its Relation to Time and Succession; On the Relations of Dreaming, Insanity, etc.; On the Memory, as affected by Age and Disease; and on Instincts and Habits.

The circulation of Dr. Holland's book will not be limited to the Profession; and we rejoice to think, that the more extensively it is read by the public, and the higher the intellectual attainments of that public, the higher will our Profession stand in its estimation. We strongly advise medical men to read it, for the sound views it inculcates on some of the most difficult and abstruse questions that come before them, as well as for the intellectual treat it will afford them; and we also strongly advise them to favour its perusal, especially by all those laymen of education who have been caught by the sophistry of the followers of Mesmer or Hahnemann.

The Oration delivered March 8, 1852, *before the Medical Society of London at the Seventy-ninth Anniversary.* By Edwin Canton, F.R.C.S., Vice-President of the Medical Society, etc. Printed at the Request of the Society. London, 1852.

The importance of the microscope as an instrument of research in medical and medico-legal inquiries, homœopathy and its absurdities, sanitary matters, sewerage, the water supply, ventilation, and extra-mural interment; the Exhibition; and the vast importance for students of medicine of a sound preliminary education, are all ably touched on by Mr. Canton in the pamphlet before us. The style in which the Oration is written is extremely good.

GENERAL CORRESPONDENCE.

REMARKS ON CALCULI.

[To the Editor of the Medical Times and Gazette.]

Sir,—There are a few, I regret to find, among the "Members of the College of Physicians," who, being more vain of the licence of that body than proud of their Doctorate, affect to treat all who are not among the *permissi* with disdain. I fear that Dr. Griffith must be included in this category, if I may judge from the fact, that, ostensibly replying to Mr. Quekett's note, he enters into an elaborate answer to my criticism on his former communication, while ignoring my existence. Such a procedure is generally esteemed uncourteous; but let me assure Dr. Griffith, that, in so doing, he has afforded me considerable amusement, and that he is at perfect liberty, should he deem it necessary to give me a second reply, to hang his discourse on the first name that falls in his way.

Dr. Griffith has been so obliging as to explain how he manufactures cells, or rather apparent cells, from crystals of lithic acid. I have carefully and repeatedly performed the experiment according to his directions; have traced the changes which take place in lithic-acid crystals under the double influence of a solvent and circulatory motion; and the conclusion at which I have arrived is, that no experienced microscopist would run any risk of confounding these imitations of cells with real organic cells. The crystals of lithic acid, however varied in outline, are of a more or less flattened form, and composed of laminæ, superimposed in such a manner, that the centre of the crystal is much thicker than its edges. A section of such a crystal is that of a bi-convex lens. The cleavage of these crystals is in two directions: the one, parallel to the laminæ of which I have spoken; the other, at right angles with them, and transverse. Now, when we place such crystals in a very dilute solution of potass, and give a circular motion to the vessel, the edges of the crystals become rounded, and, at the same time, an equal action being exercised on the upper and lower surface, the crystal is converted into something very like a doubly-convex lens. Viewing an object of this figure by the microscope, it is quite true that some resemblance is given to a nucleated cell; but if a high power be employed, the fibrous structure of the crystalline laminæ is still distinctly visible, and affords a characteristic mark of distinction between the two objects. If the action be prolonged, the crystals are reduced to extremely thin plates, in which all appearance of nucleus has vanished; but the edges of these plates are more or less angular, and they do not present the characters of a non-nucleated cell.

After having to his own satisfaction established the fact, (?) that an apparent cell-wall may be manufactured by the process he has indicated, Dr. Griffith jumps to the conclusion, that what is applicable to crystals of lithic acid is applicable to calculi; and that the disputed cell-walls in the calculi of the horse are of the same nature as those produced artificially by his process. This conclusion is inadmissible for more than one reason, and is the result of imperfect observation. Even *à priori* reasoning would suffice to negative this statement, unless Dr. Griffith has added to his discoveries an allotropic condition of carbonate of lime capable of resisting a very prolonged action of vinegar. I have, again and again, watched with the greatest care the solution of these calculi in ordinary distilled vinegar. The calculi consist either of a single cell, or an aggregation of smaller cells, filled with carbonate of lime in a radiated crystalline condition. When placed in distilled vinegar, the margin of the radiated crystalline mass may be seen to recede gradually from, what I shall persist in calling, an organic cell wall, towards the centre of the calculus, when this is composed of one cell, and finally to disappear suddenly. So different is the appearance of the central undissolved portion of carbonate of lime from the true nucleus when this is present, viewed with a magnifying power of 400 to 600 diameters, that there is not the remotest probability that they could be confounded by any one accustomed to histological research.

If the action of the distilled vinegar be prolonged, the cell walls and nuclei remain unattacked for hours, while the vinegar still retains a strong acid reaction. This is inexplicable on the supposition, that the cell-wall and nucleus consist of carbonate of lime, for we have yet to learn that carbonate of lime is deposited in any animal body in such a state of molecular aggregation as to resist the action of acetic acid, of the strength of diluted vinegar, for any length of time.

The same result was obtained, the carbonate of lime was dissolved out, the cell-walls resisted the action of hydrochloric acid, diluted with four parts of water, and the liquid retained at the termination of the experiment a strong acid reaction. I am not aware of any form of carbonate of lime, unaltered by heat, that is capable of resisting so powerful a solvent for any such length of time.

The carbonate of lime calculi, after having been burned to whiteness, before the blowpipe, present very curious and beautiful reactions with acids under the microscope, which Dr. Griffith has pretty accurately described, but miserably misinterpreted. I shall, I believe, have the pleasure of explaining to him the real cause of the phenomena. When these calculi, after being heated to redness for ten minutes or more in the blowpipe-flame, until reduced to a perfectly white powder, are placed under the microscope, with a power of 220 diameters, in distilled vinegar or hydrochloric acid, dissolved with four parts of water, they are acted on much more slowly than the calculi in their ordinary state. It is quite true, that they are surrounded by a more transparent circle, and that a globular mass is seen in the centre of the sphere, which might be readily mistaken for a nucleus by any one unaccustomed to the observation of true organic

cells. The radiated crystalline arrangement of the carbonate of lime is distinctly seen becoming gradually reduced to a few lines by the progress of solution. A very beautiful series of concentric circles is also occasionally observed at the same time. As this process of solution progresses, the central globular mass becomes more transparent, and finally disappears, leaving a perfect hollow sphere, sometimes with a granulated aspect, at others transparent. This hollow sphere retains its perfectly spherical form when put in motion. After a time a hole is perceived in the sphere, or it splits into hemispheres or cup-shaped bodies, with irregular fractured edges, finally becoming thinner and thinner, until it disappears, if excess of acid of the same strength be present. It is entirely a mistake, that these hollow spheres are insoluble in dilute acetic acid of the strength of distilled vinegar. They are slowly soluble, and entirely disappear, if sufficient time be allowed for solution.

Dr. Griffith attributes this peculiar process of solution to a difference of molecular aggregation between the superficial layer of the calculus and its interior. Had he been aware of the action of heat on carbonate of lime, he would have been able to give a much more rational explanation of this very interesting phenomenon. When carbonate of lime, especially if in contact with organic matter, is heated before the blowpipe, or in large quantities in a crucible, a part of the carbonic acid is removed by heat, and a mixture or compound of carbonate of lime and quick-lime results, which is slowly acted on by acids; still, however, yielding a considerable amount of carbonic acid. Now, in heating these globular caculi, it is sufficiently evident that the surface is reduced to this condition by the action of heat, and that the interior remains in the condition of carbonate of lime. When, then, the calcined calculi are acted on by an acid, the unaltered carbonate of lime within is more rapidly dissolved than the partially-reduced carbonate at the surface, leaving the shell, which, in Dr. Griffith's eyes, so much resembles an organic cell. The solution of the unaltered carbonate of lime goes on from the circumference to the centre, producing the appearance of the globular nucleus, which, as I have already said, is so different from the nucleus of an organic cell, that no experienced microscopist would run any risk of confounding the two objects.

These calculi are renal. Mr. Quekett has seen them in great numbers within the tubuli of the kidney; and there is no doubt that the cell-walls which enclose the carbonate of lime are renal epithelial cells, in which the carbonate of lime has been abnormally deposited.

If Dr. Griffith had read Mr. Quekett's Lecture with the attention it deserved, or if he had attended the beautiful course of Demonstrations of Histology, at the College of Surgeons, last winter, he would have seen, that nothing is more common in the animal series than the deposit of carbonate of lime, either in an amorphous or crystalline form, in true organic nucleated cells.

You, Sir, would have received this note much earlier, had I been enabled to obtain a sufficient supply of the calculi for examination; but I hope that the interval of two months will not have exhausted the interest of the subject.

I am, &c. PH. B. AYRES, M.D. Lond.

Wandsworth-road.

A FEW WORDS UPON THE PRESENT BENEVOLENT MOVEMENT IN AID OF THE VARIOUS MEDICAL PROVIDENT INSTITUTIONS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I was truly grieved to see in the *Medical Times and Gazette* of the 5th June, a letter from Mr. Newnham, (a most kind-hearted and benevolent man, and one who has been instrumental in relieving the wants and distresses of many starving members of the Medical Profession, their widows and orphans;) that letter contains much that is true, in the relief afforded from the Benevolent Fund, and I, for one, hope that that fund will increase and continue to pour forth its blessings; and had that letter confined itself exclusively to the benefits of the fund, it would have been well; but it goes on to state the imperfections and impossibilities of the "College" recently projected, (and which bids fair to arrive at completion if time be given). I do think it would have been far better not to have made any allusion to it, although Mr. Newnham's concluding remarks express a desire, that those who subscribe to the one should, also, to the other; but many might be deterred from doing so after reading Mr. Newnham's observations, when he says that the plan is likely to fail from the many objects it attempts to embrace.

Mr. Propert is highly deserving of our warmest and best thanks for his untiring exertions in promoting so desirable an object; and Mr. Daniell is equally entitled to our admiration for the zeal displayed in the plan he has submitted to the Profession, as well as all those who have been instrumental in establishing County Benevolent Societies, like Mr. Martin, of Reigate, who, in the year 1812, with some few medical brethren, assembled at the Coffee-house, Epsom, and formed a Society, called the "Surrey Medical Benevolent Society;" the object of which is to relieve distressed members, widows, and orphans, belonging to the Society. I myself became a member the following year, 1813, and our stock now amounts to 5150*l.*; out of the interest of which two widows have an annual allowance, which enables them to move in a respectable way in society, and many others have, at various times, also received assistance. I believe there are many more of the like kind in the provinces, pouring forth their blessings. Now, each Society possesses claims for our support and attention, and I cannot see why one should clash or interfere with the other; and I am confident it would be far better for the projectors of one plan not to find fault with, or doubt the success of the other. It is expected, that every medical practitioner, who loves his profession, should subscribe either to the one or other, or even to all, if he can do so conveniently; but I have solicited many who possess the means, but who have not the benevolence to subscribe to any; and I do think that a distinction should be made between those who have shown a disposition (when able) to assist in the promotion of benevolent medical institutions, and those who have not; and if proper and just reasons be not given why they have declined assisting in the support of such, I do not see that they are entitled, should circumstances so transpire as to need it, to our commiseration.

At our public meetings, like the one held recently at the London Tavern, at which the Earl of Carlisle so ably presided, when the health of gentlemen present who promote other benevolent medical institutions is proposed, they, in returning thanks, should not make any allusion to the particular schemes they advocate, as being superior to the one they are expressly met to support. It tends to do harm, by destroying the harmony and good feeling of the company, and upon that occasion called forth marks of disapprobation, when one of the speakers addressed the meeting, which in all probability hurt the feelings of the gentleman himself, and did his cause much mischief. Let us, then, go on cheerfully in the various acts of benevolence, each in the way he judges best; but do not let us find fault with, and strive to injure any scheme which we cannot countenance and support. I am, &c.

Croydon. GEORGE BOTTOMLEY.

THE BALL-AND-SOCKET FRACTURE SWING.

[To the Editor of the Medical Times and Gazette.]

SIR,—I regret that up to the present time my engagements have prevented my perusal of Mr. Grantham's letter in your Journal for May 15th, on the subject of the fracture swing.

If that gentleman will kindly re-peruse my former communication on this subject, he will readily observe, that I acknowledge in general terms the previous introduction of the principle; and only ventured to call attention to the ball and socket swing from the conviction, that fractures of the leg were not more generally treated by suspension, only because the swings in use are incomplete, and fail to carry out the principle.

But there is one point in Mr. Grantham's letter which I am sure all reflecting persons will thank that gentleman for mentioning, and, as a general question, it is most important. I allude to the too frequent want of mechanical knowledge and skill which many of our surgeons display, and the absence of any system of education on the subject.

I am confident, that every observant practitioner will readily call to mind numerous instances in which the want of mechanical tact on the part of a surgeon has produced much suffering to the patient, while it has retarded, if not prevented, the due effect of a really scientific mode of treatment.

Undoubtedly the theory and study of surgery are its highest claims; but let us not neglect that, the absence of which, causes the greatest suffering to our patients, and in the possession of which a surgeon is enabled readily to carry out the dictates of science, economise pain, and accomplish what is impossible to those who, whatever may be the extent of their knowledge, cannot appreciate a straight line, or perform the most simple mechanical operation with any degree of certainty.

But to return to the more immediate subject of this letter. Mr. Grantham supports the original leg swing (composed of a shelf, suspended by four cords from the corners) for its simplicity's sake.

Undoubtedly this latter is a most important feature in any apparatus intended for general use; but it must not be forgotten,

that it is first necessary the contrivance should attain all the objects for which it was constructed, and which I hold is not the case in this instance.

It will best answer our present purpose to divide the treatment of fractures of the lower extremity into two classes. The limb may be placed in splints and put in any fixed support which the surgeon may deem best; or the splints being applied, it may be put into some contrivance, allowing of free motion.

If the first plan is adopted, the support upon which the limb is placed cannot be too firm, neither can the limb be too securely fixed within it; that position, as a general rule, being chosen which is the most comfortable to the patient.

If, on the other hand, a support is selected possessing motion, its movements cannot be too free, or the basement from which it hangs too firm; for upon the facility with which the limb follows the spontaneous movements of the body, depends the security from motion of the fractured extremities of bone, and the consequent success of the apparatus employed.

If this is granted, then freedom of motion in every direction is the characteristic which ought to appertain to such an apparatus, and in proportion to the extent in which it fails in this is it imperfect. With one exception, those in use up to the present time possess a very limited degree of motion; but of these, the mode adopted at the London Hospital, and introduced by Mr. Luke, is at once the most simple and effective, and the plan of all others which, in emergencies such as the battle-field or obscure mining practice, will always prove the most effective in the hands of surgeons who, desirous to relieve human suffering to the greatest extent, are not prejudiced in favour of the fixed mode of treatment. The success attending Mr. Luke's adoption of the suspensory treatment of fractures of the leg is best shown by his own words. He says: "Fractures of the leg were a constant trouble to me before I suspended them; now, I rarely meet with a case which gives me any.

If, then, the success of a partial adoption of the principle is so great, surely we may hope, if we can render it more perfect, that our triumph will be comparatively greater.

I cannot allow that the apparatus described by Mr. Grantham has not been superseded. Mr. Luke's system is at once more simple and effective, while Mr. Salter's is better adapted for some cases, but possesses the faults in common with Mr. Grantham's, in being suspended from the centre, and in having its hammock formed of a permanent and water-proof material, (Mackintosh,) which promotes filth, prevents the free access of air to the limb, and cannot be opened at any part, should such a step be necessary, without much injury to the swing.

No limb can be at perfect rest which lies in a swing suspended from a central point, in consequence of the greater weight of the upper portion of the leg, and the necessary tendency of the foot to rise, or, in other words, of the leg to become straight, which will invariably occur whenever the patient loses his voluntary power over it, as in sleep. At the same time, such an arrangement of the swing may be desirable in some unusual cases, and should, therefore, be provided for.

As I remarked in my former communication, the beam of the swing should be suspended from a point, (generally from 1½ to 2½ inches from the centre,) by which the leg lies in the hammock perfectly horizontal, without effort on the part of the patient.

Another important point in which the swing mentioned in Mr. Grantham's letter appears at fault is, that the leg rests upon a padded board, in adopting which we retain some of the worst faults of the old peg-box, without a commensurate benefit.

I now come to the last point for discussion, namely, lateral movement, with perfectly free motion in every direction, and it may be briefly disposed of.

For, if the advantage of the suspensory treatment is, in the main, that it enables the patient to make necessary movements in bed without disturbing the fracture, undoubtedly it is advisable that the limb should be free to follow the movements of the body in any direction without check; while, in proportion to the universality and ease of movement, will be the improbability of displacement of the fracture. Again, although the adoption of the swing will, I doubt not, to a very great degree, prevent the occurrence of muscular spasm, yet it is important that, should it occur, the entire limb should more readily move *en masse*, than the fractured ends of bone upon each other.

But there are some patients who, from great natural restlessness of constitution, fidget themselves so recklessly, and are so callous to instructions, that they will turn their legs quite round in the swing. I have, however, observed, that these patients will accomplish the same if a more fixed apparatus is employed, and will displace their limbs if supported by the peg-box.

In the treatment of such cases, therefore, it is most important that the movement should be unlimited up to a certain point; and though it is necessary to curtail the extent of the lateral motion, by means of a cord fastened at the middle to the centre beam, and at each end, to the sides of the hammock, allowing of free movements on either side up to the limit considered necessary, the movement up to this point cannot be too free.

I will not again trouble you with the enumeration of all the advantages, constitutional as well as local, which are attached to the use of a properly formed leg swing, but would briefly remark upon the importance of a few; and, first, of the universal and almost luxurious support afforded by a common calico hammock, in place of a padded board, also the cleanliness and free access of air which it allows of; secondly, the perfect state of muscular repose gained by the point of suspension being over the centre of gravity, and not the centre of the swing; thirdly, the uninterrupted view of the spine of the tibia, gained by the necessary use of but little bandage; and, lastly, in compound fractures, the facility with which wounds may be dressed.

The constitutional advantages must be even more apparent. In the better retained health, absence of bed-sores, and a lessened amount of that troublesome symptom, stiffness of the joints.

There are also other affections in which the ball-and-socket swing may prove highly useful, particularly in those of the bones of the leg.

I will now draw these observations to a conclusion, regretting they should have proved longer than I had intended. I should not, indeed, have troubled you with them at the present time, had I not keenly felt that fracture-swings would have been in general use long since had they been more generally understood; and I trust, that my support of the principle of suspension and free movement will not be misconstrued into an undue advocacy of the apparatus which has suggested itself to my mind. On the contrary, I shall only be too pleased if others can suggest any alterations which will tend to carry out the principle more fully, rather than discard it because it does not realise their expectations at the first trial. I mention this latter point for reasons which a paragraph in the former portion of this communication will render obvious. Again regretting the length of this communication,

I am, Sir, &c.

Rye, Sussex. ALFRED ROBERTS.

TREATMENT OF PSORA.

[To the Editor of the Medical Times and Gazette.]

SIR,—It is usual among most medical practitioners to consider sulphur, in the form of ointment or bath, as the only remedy in scabies; I am well aware some use mercurial unguents. I do not deny the specific action of sulphur; I only wish to observe, that I use a very simple remedy, (taught me by a district medical officer to one of our largest metropolitan unions,) which is the simple inunction with hog's lard and the warm bath, the latter not being essential; the recovery takes place in a few days. I need not descant upon the simplicity and cheapness of the remedy, but beg to draw attention to its worth in private practice, where, if we visit a lady afflicted with scabies, and tell her honestly and plainly, saying, Madam, you have got the itch!—in nine cases out of ten she would discredit your statement, and be highly offended; so, also, if you sent the ordinary remedy, it would very likely lead her to imagine she had the complaint. I can quote an instance which occurred to myself. Visiting a lady, who said she was tormented by a breaking out and great itching,—I said, Your blood is in a bad state, you must apply the ointment I send, and take some cooling medicine. I sent, of course, sulphur ointment. Next day, on my calling, she said, "I think it must be the itch I have." I said, "Why do you think so?" "Because," said she, "you sent me sulphur-ointment, just what the nurse-maid had when she had the itch." I then confessed I did not like to tell her the truth when I first saw her. By inserting this you will oblige,

Yours, &c. J. C. BARRY, M.R.C.S., L.S.A.

London.

DEATHS FROM CHLOROFORM IN SCOTLAND.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a paper which I read at the Medical Society of London, a few weeks ago, on the cause and prevention of death from chloroform, a report of which appeared in your journal, I gave an account of all the deaths from the administration of chloroform, of which I could find any record. I was afterwards informed, however, on undoubted testimony, in two different quarters, of the death of a little boy in the Infirmary at Glasgow, whilst inhaling chloroform, in order to have the bladder sounded

for stone, some two years ago. No account of this case has ever been published. A death from chloroform occurred in a toe-nail operation at Govan, near Glasgow, in 1848, and the only account the Profession has ever had of this is a brief notice in the *Glasgow Herald*, which was copied into the medical journals. The particulars were, indeed, published, of the case of the lad Arthur Walker, of Aberdeen,—one of those cases in which death occurred from breathing chloroform for amusement, when no one was present.

But a fatal accident is so much a matter of course, from this proceeding, that such instances do not possess the interest or importance which attaches to cases of death from chloroform in surgical operations.

I have heard it said, that there may have been a number of deaths from chloroform in Scotland, of which we have not heard, as there are no coroners' inquests in that country to insure publicity. I am inclined to think there have been others besides the two I have mentioned, for I have been informed through the journals, and privately, of several cases in which the patients very nearly expired. Dr. Simpson would, no doubt, from his influence and connexion, be able to obtain every information on this point without much trouble; and, if he were to publish the particulars of the deaths from chloroform in Scotland, he would add another to the many services which he has conferred on the public and the Profession in connexion with anæsthetics.

I am, &c. JOHN SNOW, M.D.

Sackville-street.

DR. M'WILLIAM ON YELLOW FEVER.

[To the Editor of the Medical Times and Gazette,]

SIR,—In your Journal of June 5, is a letter signed "Thos. Baker," purporting to be a refutation of the views held by Dr. M'William concerning the infectious nature of yellow fever. I have very little doubt, that many of your readers, like myself, will say, Who is Mr. Thos. Baker? And indeed, Sir, the question appears very reasonable; for we naturally like to know what value we may set on those who place themselves in the light of authorities.

In the mean time, will you permit me to ask your logical correspondent a question or two?

Starting with the belief, that yellow fever is caused by *something*, perhaps Mr. Baker can first tell us what that *something* is?

Sir Wm. Burnett, Mr. Baker's great authority, acknowledges, that any fever may become infectious. He says: "I do not mean to deny the possibility of this or any other fever becoming infectious under such circumstances as attended that in the Eclair." It matters not, I imagine, whether infection is proved to happen over a "Bolam bog," in a "Black-hole," or on board a steam-ship; we must still acknowledge that something infects. It is not "heat," it is not "moisture," it is not "a foul hold," it is not "drunkenness," it is not "want of ventilation," it is not "overcrowding," nor a combination of any or all of these which can produce such a disease as yellow fever, for, if such were the case, it would never be absent from our shores.

Dr. Robert Williams, whose "Elements of Medicine" might enlighten Mr. Baker a little, has, in the introduction to his book, the following passage:—"The definite action of causes is the basis of human knowledge, and is equally true in medicine as in every other science." Archbishop Whately would not demur to this, though he might question whether there ever was such a person as Napoleon Bonaparte.(a)

Now, Sir, I would ask Mr. Thomas Baker if he agrees with Sir W. Burnett and the Board of Health in the belief that, under certain conditions, an endemic fever, usually considered to be neither infectious nor contagious, may assume the characters of an infectious disease?

Another fair question is, What does Mr. Baker understand by the word "contagion"? Will he also explain to us what is implied in the word "infection"? It is quite clear, that infection implies the action of something that infects, or, in other words, there is a cause, and it is "the definite action of causes" of infection upon which we require enlightenment.

Mr. Baker seems to lose sight of the fact, that a disease may be simply contagious, as syphilis—contagious and infectious, as small-pox—or infectious only, as hooping-cough. It is on the misunderstanding and wilful perversion of the words "infection" and "contagion" that the whole controversy rests between the so-called contagionists and non-contagionists.

The Board of Health Report on Quarantine, issued in 1849, so confounds and mystifies the subject of contagion, that I would defy any man, unless professionally educated, to fathom the statements and opinions contained in the pages of that book.

Here, Sir, for the present, I leave the subject, in the hope that your energetic correspondent, having challenged the Profession, may be honourable enough to explain distinctly the meaning he appends to the words above-mentioned, for, until this is done, argument is out of the question, though controversy may abound.

I am, &c. INQUISITOR.

(a) "Historic Doubts," etc.

[To the Editor of the Medical Times and Gazette.]

SIR,—In this week's number of the *Medical Times and Gazette*, a Mr. Baker, a clerk at the Board of Health, has been put forward as its advocate. I think Mr. Baker had better attend to the duties of his junior clerkship. Your remarks are quite right as regards the members of the Board; they ought to have been medical men. The only practical man among them is Dr. Southwood Smith, and he is crippled by Mr. Chadwick, who is, in fact, the Board, and who has all the patronage; and, before he is done with it, will make as great a mess of it as he did of the Andover Union under the Poor-law. I am, &c.

Charles-street, Westminster. H. WILSON.

EXTRAMURAL SEPULTURE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a recent Number you have inserted a letter, signed "W. Hamilton," in which he says, "Perhaps you are not aware that Mr. Walker was applied to, to aid the Government in bringing forward a working Bill on extramural interment, so that an Act might be prepared that would remedy the evil; he refused, and the clerical interests stepped in to mar the benefits to the community of his ten years' campaign."

Allow me, as a friend of Mr. Walker, through the medium of your Journal, to disclaim the accuracy of the above observations. Mr. Walker never was applied to, to aid the Government in the way alleged; nor was it from any refusal on his part that the clerical interests step in to mar the benefits to the community of his campaign, as your correspondent mentions.

When the Board of Health made their Report on a general scheme for extramural interment, all the allusion which it contained to Mr. Walker's fifteen years' labours in the cause of exposing the wrong, was two lines and a half; and, as regards the Government remedy, Mr. Walker only discovered what it was by procuring a copy of the Bill introduced in 1850, by Sir George Grey, for the purpose of "better interring the dead in and near London."

Mr. Walker has never, at any time, advocated the better interring of the dead in and near London. He has spent half a lifetime, and several thousand pounds, in inculcating the reverse. During the passing of the Metropolitan Interments Act, he exerted himself to the best of his ability to have it so amended as to render it unobjectionable; but, as he failed in that attempt, he is not one of those who regret that the Board of Health should have got that Act, and nothing but that Act.

Although the public have not, as yet, responded as they ought to the call made by the Walker Testimonial Committee, I still trust the time is not distant when his long and eminent services in the cause of the abolition of burial within towns and cities will be properly appreciated. Mr. Walker is one of those men who have worked for the common good, not with an eye to such wages as what a long subscription-list indicates; but from a love of the work itself. In due time, then, his labours will surely meet their well-merited reward. In a country which has so munificently recompensed the labours of the statesman who has given us cheap bread, it is impossible to suppose that the surgeon who, at the risk of health, and a large interference with his professional avocations, has done so great a work as to purify the vital air in all centres of population of that which loads it with pestilence and death, will not fail to receive some substantial proof of the gratitude and thanks of society at large. I am, &c.

ONE OF THE COMMITTEE OF THE WALKER

London. TESTIMONIAL FUND.

BETHLEM HOSPITAL AND ITS MEDICAL STAFF OF OFFICERS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I read with much interest your remarks on Bethlem and its management; they are much to the point, and may be of great service.

There can be no doubt that the patients at this Royal hospital,

particularly the criminals, have not been treated, from natoral causes, as their circumstances required.

"What rays of sunshine gladden and cheer its desponding and unhappy inmates?" What a difference in the treatment of criminal lunatics at other asylums!

To one asylum which I could mention, several incurable criminal lunatics were sent, many of whom, ere long, I trust, will be liberated, and sent to their own homes,—some having exceeded their term of imprisonment, and are now convalescent.

As regards your remarks on the duties of the physician, I would suggest to your notice, the necessity of urging on the Committee the propriety of taking the rules of some well-conducted asylum as a guide.

For instance, the Royal Asylum of Edinburgh, where there is a physician-superintendent, Dr. Skae, and two assistant-physicians, Dr. Sherlock and Dr. Rowe, and the average number of patients does not very much exceed that at Bethlem. At Dumfries, the asylum under the charge of Dr. Browne, a similar constitution exists.

At several hospitals for the insane in England and Scotland, where there are but 250 or 300 patients, there are two resident medical officers.

The assistant-physician at Bethlem would find plenty to occupy his leisure hours for the interests of the patients, in carrying out the directions of the superintendent, in directing the keeping of the case-books, and frequently in the day visiting the various wards, to all of which he should have unlimited access. A person holding such an appointment should not be an apothecary, his duties not peculiarly consisting in "dispensing and administering medicines, the extraction of teeth and administration of enemata, passing catheters and keeping accounts."

I would further suggest, that the position of the assistant medical officer should be second to no one in the establishment but the physician superintendent, such as is the case in most county asylums in England. He should superintend the duties of the subordinates engaged in the treatment of the insane; and, as the rules of the Wakefield Asylum have it, in the absence of the Director, "be the responsible manager of the Institution;" and, at the Northampton and Wilts County Asylum, he is required to visit every patient at least twice daily.

He should perform the *post-mortem* examinations, as the physician's assistants do in the London hospitals,—for instance, at King's College and University College, where there are physicians to prescribe, assistants to direct, and clinical clerks to observe and write.

A man well calculated to perform the duties of assistant medical officer at Bethlem with energy and zeal must be very necessary; and, without such a person, how is it possible for the case-books to be kept? To obtain all the information alone, where so many are regularly admitted and discharged, can be no small amount of labour. The physician could not do this; clinical clerks could not. It would, therefore, be the peculiar duty of the assistant-physician to attend to this.

The assistant medical official should be paid liberally, treated as a gentleman. His position should be similar to that of the assistant-surgeon in the army; and there would be no difficulty in obtaining candidates for this appointment who have distinguished themselves at the London schools, and, in addition, had experience in the modern treatment of the insane, and not prejudiced observers; surely it would be unfair to act otherwise.

I am, &c. AN EX-SUPERINTENDENT.

SUPERINTENDENTS OF COUNTY LUNATIC ASYLUMS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to ask a "A County Superintendent," whether he allows other officers of Asylums the same right of appeal to a committee of magistrates as he demands for himself?

It may be settled among the majority of superintendents of asylums that such a system should exist, as that proposed by your correspondent. But are they the only parties whose comfort should be studied? Every officer of an asylum should have as much opportunity of appealing to the Committee as the superintendent himself; and if that be granted it is not possible for that officer to sit at the Board.

I cannot agree with your correspondent in thinking, that one man should be delegated with so much power as is proposed by him.

Superintendents at the present time have sufficient power; and only increase this, and things will be worse.

If you visit asylums which work well, where there is unanimity among the officers, and a proper respect and feeling towards the officer in command, these will not be found to be those institutions where the superintendent is at once director, treasurer, superintendent, physician, house surgeon, etc. etc.

Such was the case formerly at Hanwell, but being found to be bad, it was abolished.

There is a great advantage, to my mind, in having a Committee which can be appealed to, and which will take the responsibility from the shoulders of one man. I am, Sir, &c.

JUSTITIA.

ON THE UTERINE SOUND.

[To the Editor of the Medical Times and Gazette.]

SIR,—Nothing could more forcibly illustrate the propriety of criticising the statements in respect to the practical value of the uterine sound, than the letter of Dr. Higgins, in the late Number of your journal (May 15). In an endeavour to repress various "abominations" in the treatment of uterine disease, "alike uncalled-for by the nature of the disease, and demoralizing to the female subjected to them without just cause," I examined the clinical facts contained in some papers "On Dysmenorrhœa, by Edward Rigby, M.D." I there showed, from Dr. Rigby's own words, that some, at least, of the published cases were not examples of the disease—obstructive dysmenorrhœa—which he considered to be present; that the diagnosis was erroneous; and that the treatment employed was uncalled-for, and hence improper. When examining these cases, I quoted the words of Dr. Rigby:—"The uterine sound passed more than 2½ inches;" but it appears the exact words are, "rather more than 2½ inches." Dr. Higgins points this out, and asks, "For what purpose is this inaccuracy,—this omission." I reply, For no purpose whatever—it was accidental. The words "rather," and "more," are of no value in the sentence; they may both be omitted, and the facts of the case will remain the same; that is, that when the uterine sound passes 2½ inches in the virgin uterus, it penetrates the internal orifice, and consequently this cannot be constricted and have occasioned obstructive dysmenorrhœa, as Dr. Rigby considered. Nay, not only may the words "rather more" be omitted, but the half inch even may be removed, and the facts will remain the same; for if the sound passes but two inches, it penetrates the internal orifice in the virgin uterus. This wish, then, to establish an improper "purpose" is unfortunate; but, while it fails in its aim, it shows the heedless manner in which this instrument is used, even by those who advocate its employment. They appear to overlook, that when the sound is introduced 2½ inches, it penetrates the full extent of the uterine cavities; that it is introduced more than half an inch further than can serve any practical object, even according to their view of the matter; and that this unnecessary "poking" of the cavity of the body of the uterus is fraught with much serious consequences to the patient, and attains no useful information.

Dr. Higgins says:—"The proper dimensions of the uterine sound, as given in my paper, (that is, one-eighth of an inch in diameter,) are not too large for a normal uterine canal." I, however, demur to this statement.

Neither the internal, nor even the external orifice of a healthy virgin uterus will admit an instrument one-eighth of an inch to pass through. But, as this is a point of measurement which can be readily determined during a *post-mortem* examination, or in the dissecting-rooms of London, I leave it to those interested in the question to decide for themselves. He adds, "The uterine canal, just as the male urethra, need not be entirely closed to produce serious functional derangements of the catamenial secretion." Now, granted that this proposition be correct, how does it bear upon the subject under discussion? The uterine sound passed 2½ inches; hence the canal was not "entirely closed," nor was it even partially closed; for, according to Dr. Higgins, the sound is not "too large for a normal uterine canal." Now, the inference from this is obvious, viz., that when the sound passes through the uterine canal, this canal is of its normal dimensions; that no obstruction to the flow of the catamenia would exist; that, under these circumstances, the diagnosis of "obstructive dysmenorrhœa" would be erroneous, and, consequently, the treatment directed to remove the imaginary obstruction uncalled for and improper. I am obliged for this confirmation of the statements I have advanced, and would suggest to Dr. Higgins the propriety of ascertaining with more precision the dimensions of the uterine canal before incurring the risk to his patients of unnecessary dilatation, or defending others who employ "blades made of well-tempered steel," or knives ingeniously contrived for the purpose of removing obstructions, which, according to their own showing, did not exist.

Dr. Higgins further adds, that I attempted to show his "treatment of obstructed dysmenorrhœa was as uncalled for, and, conse-

quently, as improper, as Dr. Rigby's;" that I insinuated,—what is nowhere stated,—that in this case he "passed the instrument through the uterine canal, which (he) did not do." Dr. Higgins is again in error. I did not insinuate that the sound passed through the uterine canal, but stated, that the bulb of the instrument was much too large to pass the os internum uteri in the healthy state, and, *à fortiori*, in a contracted condition; and, consequently, the sound "could not afford any indication of a constriction of this orifice." He adds, "For surely, as with the male urethra, a stricture, or contracted condition of this canal, may be ascertained, without penetrating the constriction, by the obstruction which the instrument receives at the narrowed part." Again is he wrong. The male urethra is, with slight variation, of the same diameter throughout, the narrowest part being at the orifice, and an instrument, once introduced, will pass along the whole canal. The uterine canal differs essentially from this condition. The external orifice is smaller than the canal of the cervix, and considerably larger than the internal orifice; so that, in the healthy state, an instrument which will enter at the external orifice is obstructed at the upper part of the cervical canal, where it becomes smaller to form the internal orifice. The analogy, then, between the urethral canal and the uterine canal will not hold good. It is surprising that practitioners do not make themselves acquainted with the healthy condition of the part, and thus avoid the error of mistaking a natural for a diseased state. I confess being unable to understand the meaning of the following:—"If the escape of a brownish, bloody coloured fluid, from a dilated os and cervix uteri, be not an indication of a canal (whether quite pervious or not) preternaturally and relatively too small for its purposes, I ask, what is it an indication of?" It is a strange contradiction, that the escape of fluid from an orifice and cervix uteri already known to be dilated should be considered to indicate the reverse of what was previously ascertained to exist. How can this be?

Possibly Dr. Higgins supposes, that it is an indication of a contracted state of the internal orifice; for he asks, "If this discharge be not evidence of retained menstrual fluid, what is it?" He appears not to know, that when an instrument is passed through the internal orifice of a healthy uterus, some blood almost always escapes, and, when congestion or chronic inflammation of the organ is present, the amount of hæmorrhage is much increased. This is the explanation of the "discharge," which is no evidence whatever of "retained menstroal fluid," but even evidence of a contrary nature, viz., that considerable risk is incurred by "poking" the uterus during these states, seeing that it is exactly in such cases that acute inflammation so often follows the use of the sound.

I have long thought that the use of the uterine sound must be based on some erroneous notions of those who employ it; but I was not prepared for so complete a demonstration of this opinion as the writings of Dr. Rigby and Dr. Higgins afford. These writings also show the necessity of examining the accuracy of published statements; for, although their fallacy is easily shown, yet, as a certain degree of specious argument prevails, they may deceive the unwary, and be the means of inflicting much practical mischief. May I not now add, that if no better reasons can be given for the employment of the uterine sound than they contain, this instrument will quickly fall into merited oblivion.

I am, &c. M.D. Londin.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

J. Hodgson, Esq., F.R.S., President, in the Chair.

ON SOME OF THE PRINCIPAL EFFECTS RESULTING FROM THE DETACHMENT OF FIBRINOUS DEPOSITS FROM THE INTERIOR OF THE HEART, AND THEIR MIXTURE WITH THE CIRCULATING BLOOD.

By WILLIAM SENHOUSE KIRKES, M.D.

[Communicated by Dr. BURROWS, F.R.S.]

As an introduction to the subject, the author observed, that it was a clearly-established fact, that the fibrinous principle of the blood might, under certain circumstances, separate from the circulating fluid, and be deposited within the vascular system, especially on the valves of the heart. The forms of fibrinous concretions to which the following observations especially applied, were, first, the masses usually described as Laennec's globular excrescences; and, secondly, the granular and warty growths adhering to the valves, and presenting innumerable varieties, from mere granules to large irregular fungous or cauliflower excrescences, projecting into the cavities of the heart. These growths, when once formed, whatever might be their origin, were full of peril, and would often remain so, long after the circumstances which gave rise to them had passed away. When of large size, or loosely adherent, they might at any time be detached from the valves, and conveyed with the circulating blood, until arrested within some arterial canal, which might thus become completely plugged up, and the supply of blood to an important part be suddenly cut off, from which serious if not fatal results would ensue; or, smaller masses might be detached, and pass on into arteries of much less size, or even into the capillaries, whence congestion, followed by stagnation and coagulation of the blood, and all the consequent changes such coagulated blood is liable to undergo in the living body, would necessarily follow. Many singular morbid appearances observed in internal organs, and not well accounted for, were probably brought about in this manner. Again, the masses of fibrin might soften, break up, and discharge the finely granular material resulting from their disintegration into the circulating blood, and, contaminating this fluid, might excite symptoms very similar to those observed in phlebitis, typhus, and other analogous blood diseases. Thus the fibrinous material detached from the valves, or any other part of the interior of the heart, might be the cause of serious secondary mischief. The parts of the vascular system in which these transmitted masses of fibrin might be found, would in great measure depend upon whether they were detached from the right or left cavities of the heart. Thus, if from the left, they would pass into the aorta and its subdivisions, and would be arrested in any of the systemic arteries or their ramifications, and especially in those organs which receive large quantities of blood direct from the left side of the heart, as the brain, spleen, and kidneys: on the contrary, if escaping from the right cavities, the lungs would necessarily become the primary, if not the exclusive, seat of their ultimate deposition. A division of the subject being thus naturally formed, the author proposed to consider the subject, first, as to the remote effects resulting from the separation of fibrinous deposits from the valves or cavities of the left side; and, secondly, as to the corresponding effects produced by the detachment of like deposits from the valves or cavities of the right side of the heart. The author then proceeded to elucidate the first branch of the subject, in which masses of some magnitude were detached from the left side, and arrested in an arterial channel of notable size. This pathological fact was illustrated by three cases, in many respects identical; for, in each, death appeared to ensue from softening of the brain, consequent on obstruction in one of the principal cerebral arteries, by a mass of fibrinous material, apparently detached from growths on the left valves. The first case was that of a female, aged 34, of pale and delicate aspect. She had suffered from rheumatic pains, and there was a loud systolic murmur heard over the entire cardiac region. While under treatment for these symptoms, she suddenly fell back as if fainting. She was found speechless, with partial hemiplegia of the left side, but there was no loss of consciousness. The hemiplegia increased, involved the face and limbs, and gradually became complete in regard to motion; but sensation remained unimpaired. These symptoms lasted five days, when she died quietly. The *post-mortem* examination developed much congestion of the pia mater, amounting, in some places, to ecchymosis. The right corpus striatum was softened to an extreme degree, being reduced to a dirty, greyish-white pulp. In the posterior lobe of the right cerebral hemisphere was a similar spot of pale softening. The right middle cerebral artery, just at its commencement, was plugged up by a small nodule of firm, whitish, fibrinous-looking substance, not adherent to the wall, but rendering the canal almost impervious. The vessels of the brain were generally healthy, except a yellow spot or two in the coats of those at the base of the brain. The heart was enlarged; several broad white patches externally. The right valves were healthy, so also were the aorta; but the mitral valve was much diseased, the auricular surface being beset with large warty excrescences of adherent blood-stained fibrin. The right common iliac artery, about an inch above the origin of its internal branch, was blocked up by a firm, pale, laminated coagulum, which extended into the internal iliac. The pleuræ were adherent in places; liver and intestinal canal healthy; spleen large, pale, and soft, containing a yellowish-white, cheesy substance. The kidneys were pale, rough, and granular; within the cortex of the right were several large masses of yellow deposit, surrounded by patches of redness. Death had resulted, in this case, from the softening of a large portion of the right side of the brain, which the author considered to have arisen from an imperfect supply of blood, consequent on the middle cerebral artery of the same side being obstructed by a plug of fibrin. The author then discussed the sufficiency of such an

obstruction to produce the effects ascribed to it, and he brought forward many examples showing that atrophy and disorganisation usually resulted from any circumstance which materially impeded, or entirely cut off, the supply of blood to a part. The author then directed attention to the probable source of the fibrinous plug found in the middle cerebral artery. The suddenness of the cerebral symptoms rendered it probable, that the blocking up of the artery was equally sudden, and not the result of gradual coagulation of the blood within the vessel. The absence of all local mischief in the coats of the artery at the point of obstruction, as well as elsewhere, pointed to some other than local origin for the clot; and the author, at the time of the examination, formed the opinion, that a part of the fibrinous deposit on the mitral valve had become detached, and carried by the stream of blood, until arrested at the angle whence the middle cerebral proceeded. This explanation suited equally for the plug found in the common iliac; for it was quite conceivable, that portions of the loosely adherent fibrin might be easily detached by the stream of blood washing over the mitral valve, and, when once admitted into the circulating current, they would only be arrested by arriving at a vessel too small to allow their transit along its canal. Two other cases were described by the author, possessing many interesting points of resemblance: one, a female, aged 24; the other, a male, of the same age. Both were admitted into the hospital with hemiplegia of the left side; each had heart disease, indicated by a loud systolic murmur. The *post-mortem* examinations revealed the following morbid appearances common to both:—Softening of a limited portion of the brain, producing death by hemiplegia; obliteration of the cerebral artery supplying the softened part; coagula in one of the iliac arteries; fibrinous deposits in the kidneys and spleen; and the presence of fibrinous warty excrescences on the valves of the left side of the heart. So many and such rare features of resemblance could not fail to demonstrate a very close connexion between the several morbid appearances so exactly reproduced in each case. The author believed, that these three cases satisfactorily established the two following conclusions:—1st. That softening of a portion of the brain, with attendant loss of function, might result from obstruction of a main cerebral artery by the lodgment of a plug of fibrin within its canal. 2ndly. That the foreign substance thus obstructing the vessel was probably not formed there, but was derived directly from warty growths situated on the left valves of the heart. The author thought it not improbable, although in the absence of direct proof it was but supposition, till further investigation confirmed these facts, that many cases of partial and temporary paralysis suddenly ensuing in one or more limbs of young persons, especially if accompanied with signs of cardiac disease, might be due to interruption of a proper supply of nutriment to the brain by the temporary plugging up of a principal cerebral artery by fibrin, detached from a diseased valve on the left side of the heart. Other arterial branches besides those of the base of the brain, might arrest these fibrinous deposits derived from the valves of the heart. In cases 1 and 2, coagula were found in the iliac and femoral arteries; and in Case 3, in the renal. The author thought that many specimens found in museums, and supposed to illustrate the spontaneous coagulation of the blood, or the deposition of fibrin within a limited portion of an arterial trunk, were probably to be referred to the same cardiac origin; and he illustrated the point by reference to a preparation in the museum of St. Bartholomew's Hospital. The second subject of inquiry consisted of an examination into the effects produced by smaller portions of fibrin detached in a similar manner, but arrested in the minute arterial branches, or even in the capillaries. The author thought that the singular masses of yellow fibrinous substance found in the spleen and kidneys, and other organs, and hitherto described as "capillary phlebitis," "metastasis," or "fibrinous deposits," were derived from this cause. Out of twenty-one cases in which the author had observed these deposits in the spleen and kidneys, or other parts deriving blood directly from the left side of the heart, in nineteen there was disease of the valves, or of the interior of the left side of the heart. In fourteen of these there were fibrinous growths on the surface of the left valves; in the remaining five there was simple mention of valvular disease. The author thought, that the mere fact of so large a number of cases of so-called "capillary phlebitis" being associated with the presence of fibrinous deposit on the valves of the heart, suggested a very close relation between the two morbid states. The author then entered upon the third branch of this part of the subject, concerning the series of effects which might result from the introduction of fibrinous particles into the circulating blood, manifesting phenomena indicative of the existence of a morbid poison in that fluid. A case was related of a youth, aged fourteen, admitted into the hospital with obscure typhoid symptoms, the surface of the body being covered with petechiæ. Delirium, with much febrile prostration, followed; he became subsequently comatose, and died. Upon examination of the body, the surface was found covered with petechiæ. The pia mater was infiltrated with what seemed recently effused blood. The surface of the brain thus presented a blotchy appearance, and, amid these spots, were yellow-coloured patches of various size; some were of a greenish-yellow hue, and had the appearance of being smeared over with pus. The brain was unduly congested, and some ecchymosis near the surface; the cerebral arteries and sinuses healthy; several petechial spots on the surface of the heart, as well as in the cavities; and, on the auricular surface of the mitral valve, some white fibrinous vegetations, very soft and friable; a like deposit on the aortic valves, with evidences of ulceration; several yellow masses of fibrinous deposit on the surface of the spleen; cortical part of the kidney covered with minute petechial spots, in the centre of which was a buff-coloured dot; several large yellowish blotches extended deep into the substance of the cortex. The intestinal mucous surface was covered with petechial spots, which were apparent also on the mucous membrane of the bladder, pharynx, œsophagus, stomach, larynx, and trachea. The author considered the mystery of this case cleared up by the post-mortem examination. The attack had been ushered in by a severe pain in the right groin, which was rheumatic; then ensued rheumatic inflammation of the mitral and aortic valves, with ulceration of the latter, and deposition of fibrin. From these deposits portions had probably separated during life, and were transmitted with the blood to all parts of the body; and, being arrested in the capillary networks and smaller arteries, produced the various petechial and buff-coloured spots above described.

The second part of the paper related to the effects which might result from the detachment of fibrinous deposits from the right valves of the heart. Reference was made by the author to a paper on the Formation of Coagula in the Pulmonary Artery, by Mr. Paget, published in the "Transactions" of the Society, as well as to a specimen in the museum of St. Bartholomew's Hospital, in which there was deposition of fibrin on each of the pulmonary valves, with old coagula filling many of the branches of the pulmonary artery. In this case several large, solid, fibrinous masses were found in the substance of the lungs, presenting appearances not unlike portions of old pulmonary apoplexy. Lastly, the author recapitulated the principal points which he was desirous of establishing, viz.,—1st. That fibrinous concretions in the valves of the heart admit of being readily detached during life. 2ndly. That if detached and transmitted in large masses, they may suddenly block up a large artery, and thus cut off the supply of blood to an important part; if in smaller masses, they might be arrested by vessels of smaller size, and give rise to various morbid appearances in internal organs; or the particles mingled with the blood might be but the debris of softened fibrin, yet with power to produce a poisoned state of the blood, and bring on typhoid or phlebitic symptoms. 3rdly. That the effects produced and the organs affected would be in great measure determined by the side of the heart from which the fibrinous material had been detached: if from the right side, the lungs would bear the brunt of the secondary mischief; but if, as was most commonly the case, the left valves were the source, the mischief would be more widely spread, and might fall on any part, but especially on those organs which were largely and directly supplied with blood from the left side of the heart, as the brain, spleen, or kidneys.

Mr. Barlow said, that although his opinion could be of no value to the author, he could not but congratulate him on the ability, originality, and importance of his paper. Every one was aware, that, in spite of all that research had accomplished, it was still difficult, nay, impossible, to explain many cases of softening of the brain. It often happened, that a theory, even if admitted, was far from meeting all the difficulties of the case; but the contrary was to be said of that proposed ingeniously by Dr. Kirkes in reference to the examples which he had brought forward. The facts certainly concurred very pointedly indeed to favour and support the view which had been suggested,—there was the time of life of the patients which precluded the idea of atrophy from age,—there was the absence of any arterial disease or degeneration,—there was the proved obstruction by a small mass of fibrin which blocked at a point the vessel leading to the part destroyed, and that mass might clearly have been carried from the heart, as was obvious from the condition of its valves, and placed there. He had examined one of the preparations on the table, showing a blocking-up of the middle cerebral artery, and that appeared to him to have been caused in the manner suggested by the author. Of course, the explanation which had been given of ramollissement only applied, and was intended only to apply, to special cases,—cases such as those contained in the paper. What had been observed respecting the want of anastomosis of vessels conducing to the anemia, atrophy, and death, which

occurred in these cases, derived illustration and support from what had been already shown by Dr. Quain respecting that circumscribed atrophy and degeneration of the heart, which were commonly owing to occlusion or narrowing of the coronary arteries. The form of ramollissement which they were considering more resembled that which ensued occasionally from ligature of the carotid than any other; for, even if they selected the case of mere narrowing of an artery, and consequent softening, they had still to explain the cause of the degeneration of the particular vessel by the obstruction of which the mischief was occasioned; but in the instances before them, there was a simple mechanical cause of obstruction, the source of which was obvious, than which, as to its action, nothing could possibly be easier to understand. There were many other points which invited remark; but he would not venture a longer comment on this highly valuable addition to pathology.

Dr. Wrench was not disposed to go beyond the first series of phenomena, which he thought were fully proved. He could not admit, that the 2nd, 3rd, and 4th were equally satisfactory. He considered, that the effects with reference to the spleen were owing to hæmorrhage into the organ, and the same with the lungs. The results were owing to effusion; and he thought it straining the point, to refer them to the arrest of particles of lymph in the smaller vessels.

Dr. G. Burrows wished to add his testimony to the facts detailed in the paper. With respect to the second series, all the details are most accurate. In fact, the whole details are given most correctly. He had arrived at the same conclusion as the author, and attributed these cases of softening of the brain to the sudden arrest of the circulation in the vessels. He remembered the great controversy, about twenty or thirty years ago, as to the cause of ramollissement of the brain. Abercrombie attributed it to inflammation,—a view supported by Lallemand, but subsequently the publication of Rostan's work caused Abercrombie to believe, that in some cases, at least another cause might be in operation, and that defective nutrition might lead to the same result as inflammation. Not one of these writers seems to have discovered the state described by our author as in any way causative of the ramollissement. It was left for Dr. Kirkes to discover. The celebrated Andral, in his *résumé* on cerebral softening, after referring some cases to one cause, and some to another, says, that there are still some for which no cause can be assigned; they are *sui generis*. When these cases occurred in St. Bartholomew's Hospital, he (Dr. Burrows) referred to works on the subject, and found there were three cases on record which resembled them that is, sudden hemiplegia, lasting days or weeks, and after death a limited softening of the corpus striatum, optic thalamus, etc., together with valvular cardiac disease or with an aneurism of the aorta. Andral does not mention any diseased state of the cerebral arteries, nor does he allude to heart-disease as connected with the ramollissements; but he (Dr. Burrows) after hearing the paper read, and after seeing the cases, could not help connecting them together. Every one must have seen cases such as had been described. He was called, some time ago, by Dr. Hertford, of Chertsey, to see a lady, who, after protracted ill-health, (she was supposed to be consumptive,) had been afflicted suddenly with hemiplegia. The heart was diseased; there was a loud rasping systolic murmur heard all over the heart and aorta. The patient was brought to London and died here, but no *post-mortem* examination was made. This occurred five years ago, and, from Dr. Kirkes' paper, he was led to conclude, that the paralysis depended on some accidental detachment of fibrin. He was fully of opinion, that the statements in the paper respecting cerebral softening were fully proved, but he did not think the other points so clearly ascertained. They opened a wide field for investigation.

Some further remarks were offered by some Fellows of the Society, after which the meeting was adjourned.

CHEMICAL SOCIETY.

The only paper read was on a Method of Detecting the Presence of Alum in Bread and Flour.

Dr. Hofmann made a few observations on Liebig's new test for urea. No further practical information on this subject was, however, furnished than is contained in our previous notice of this test. It was suggested that a difficulty might occur in obtaining in all cases such a correct normal solution of per nitrate of mercury, used as the test liquor, as would be desirable.

Mr. Redwood exhibited a sample of aloe juice (inspissated), some of which has lately been imported, and suggested its employment as a source of aloine.

The Secretary then exhibited a specimen of a new salt of quinine, discovered by Mr. W. B. Herapath, possessing the power of polarizing a ray of light like tourmaline, and, at certain angles of rotation, of depolarizing it like selenite. Upon dropping tincture of iodine into a solution of disulphate of quinine in diluted sulphuric acid, an abundant deposition of brilliant emerald-green crystals is obtained. It was, however, found exceedingly difficult to experiment in a satisfactory manner upon the crystals thus formed, as it was almost impossible to isolate them from their mother liquor. It was subsequently found, that by dissolving the disulphates of quinine and cinchonine of commerce in concentrated acetic acid; upon warming the solution and dropping into it a spirituous solution of iodine, carefully by small quantities at a time, and placing the mixture aside for some hours, large brilliant plates of this substance were produced. These could be readily separated from their mother liquor, and, by frequent re-crystallisation, purified. The crystals of this salt, when examined by reflected light, have a brilliant emerald-green colour, with almost a metallic lustre; they appear like portions of the elytra of cantharides, and are also very similar to murexide in appearance. When examined by transmitted light, they scarcely possess any colour; there is only a slightly olive-green tinge; but, if two crystals crossing at right angles be examined, the spot where they intersect appears as black as midnight, even if the crystals be not 1-500th of an inch in thickness. If the light used in this experiment be in the slightest degree polarized, as by reflection from a cloud, or by the blue sky, or from the glass surface of the mirror of the microscope placed at the polarizing angle 56° 45′, these little prisms immediately assume complementary colours. One appears green and the other pink, and the part at which they cross is a chocolate or deep chesnut brown, instead of black. Their chemical characters are as follow: — They are immediately redissolved upon heating the acid liquor to 180° and recrystallize on cooling. Boiling alcohol readily dissolves them, and a clear orange-yellow solution results; this, on cooling, deposits crystals in abundance, having the same optical and chemical characters, but they have lost the prismatic form, and now appear as rosettes of minute hexagonal plates, or forms derived from the hexagon by truncation of the angles. Cold alcohol does not dissolve them. Sulphuric ether and chloroform appear to have no power over the crystals. Ammonia rapidly decomposes them; this power is greatly increased by heat. A colourless solution results, and an opaque Naples-yellow precipitate remains, which is fusible at the boiling temperature of the ammoniacal liquid. A deep brownish-yellow resinous mass results; this is a compound of iodine and the alkaloid. Liquor potassæ has the same action on these crystals, but the resulting resin is deeper in colour, being now a chocolate brown. The alkaline solutions in both instances contain sulphuric and hydriodic acids.

CONTRIBUTIONS TOWARDS THE HISTORY OF TANNIC ACID.

By DR. STRECKER.

Communicated by Dr. Hofmann.

The author states, he has ascertained that tannin, when acted on by acids, yields sugar in addition to gallic acid, so that, henceforth, tannic acid may be classed with the conjugated sugar compounds. If tannic acid be thrown down from a pure solution with sulphuric acid, the precipitate boiled with water or very dilute sulphuric acid, the solution neutralised with carbonate of lead, the gallic acid now present, precipitated with acetate of lead, and the excess of this precipitant removed by sulphuretted hydrogen, the liquor, on being evaporated, will yield a syrupy residue possessing all the properties of sugar modified by acids. The author states, that he has not yet determined the quantity of sugar that is produced by a known weight of tannic acid, but suggests that the composition of tannic acid will probably have to be represented by the formula (C_{40} H_{18} O_{26}); and the transformation which tannic acid undergoes under the circumstances alluded to, would then be shown by the following equation:—

$$C_{40}\ H_{18}\ O_{26} + 10\ HO = 2\ (C_{14}\ H_8\ O_{12}) + C_{12}\ H_{12}\ O_{12}.$$

ON THE DETECTION AND QUALITATIVE SEPARATION OF TIN, ANTIMONY, AND ARSENIC,

AND ON THE RELATION EXISTING BETWEEN THESE METALS AND OTHERS WHICH ARE PRECIPITATED FROM THEIR ACID SOLUTIONS BY SULPHURETTED HYDROGEN.

By CHARLES L. BLOXAM.

After a few prefatory remarks, and a review of the principal methods hitherto proposed for effecting the object in view, the author proceeded to describe the method which he has been led to adopt, which consists in treating the precipitated sulphides of arsenic, antimony, and tin, with solution of sesquicarbonate of ammonia, which dissolves the sulphide of arsenic, and part of the sulphide of tin; the arsenic is detected in the precipitate, thrown

down from the solution by hydrochloric acid, by the test of Fresenius and Boho, while the tin is sought for in another portion of the same precipitate, by deflagrating it with nitre, precipitating the aqueous solution of the fused mass with nitric acid, reducing the tin from the precipitate by fusion with cyanide of potassium, treating the reduced metal with hydrochloric acid, and testing the solution for protochloride of tin with perchloride of mercury. Antimony and tin are detected in the precipitate left undissolved by sesquicarbonate of ammonia; this precipitate is dissolved in nitro-hydrochloric acid, and the solution boiled with excess of sesquicarbonate of ammonia, when the whole of the tin is precipitated, and part of the antimony remains in solution; the tin may be discovered by reducing the precipitate as above described, and the antimony may be precipitated as sulphide by acidulating the solution with hydrochloric acid, and passing sulphuretted hydrogen.

Some curious facts were stated respecting the insolubility of bisulphide of tin in sulphide of ammonium, in the presence of sulphides of copper and tin. Methods were described by which these difficulties may be overcome.

All the processes mentioned in the paper were verified by experiments upon mixtures containing known quantities of the various metals.

MEDICAL NEWS.

Conversazione at the Royal College of Physicians.—The President and Fellows of this College, stimulated by the success which attended their exertions last year, entertained, on Wednesday evening, a numerous body of visiters composed of the *élite* of the scientific and literary world; thus keeping pace with the gigantic social stride which rendered memorable the year 1851, and will stamp it in all future records as an epoch in the history of civilization. The salutary effect of these meetings must be patent to every one interested in the progress of ethics and philosophy, and affords an unmistakeable illustration of the spirit of the times, tending to a more generous fusion of those whom talent, guided by the same unerring principle of right, should morally place on the same footing. Gladly do we recognise this movement of the Royal College of Physicians, dictated alike by principle and policy, and sure we are, that when the sciences are as cordially blended and as ably represented as they were on Wednesday night, they cannot but leave on the mind an impression both permanent and effective. We must only remark, that the well known hospitality of the College was rather extended than diminished, and the appointments gave universal satisfaction, the excellence of which was identified with the caterers, Messrs. Staples, of the Albion. Among the visiters we observed—Lord Londesborough, Lord Headley, Lieutenant-General Sir Archibald Maclaine, Sir George Staunton, Sir Fortunatus Dwarris, Sir Charles Fellows, Sir Richard Kindersley, Sir George Clerk, Dean of Salisbury, Archdeacon Thorpe, Archdeacon Hale, Signor Di Vieenzi, Baron Parke, Justice Creswell, Serjeant Goulburn, Serjeant Stork, Mr. Wilcocks, Q.C., Professor Brande, Professor Grant, Professor Mitchell, Dr. Jelf, Professor Sedgwick, the President of the Royal College of Surgeons, Vice-President of the Royal College of Surgeons, the Revs. Robert Hawkins, Edward Monro, W. Babington, H. L. Majendie, John Jackson, E. B. Hue, — Mackenzie, and a number of the most eminent and distinguished medical men of the Metropolis.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 4th inst.:—

Clarke, J., London.
Hillas, Thomas, Brompton, Middlesex.
Longton, Edward John, Southport, Lancashire.
Naylor, George, Hon. East India Company's Service.
Reynolds, Robert, Debach, Suffolk.
Royston, Charles, Harrow-road, Paddington.
Simpson, Benjamin, Dublin.
Snell, William, Neston, Cheshire.
Stiles, Henry Tournay, Spalding, Lincolnshire.

Board of Accoucheurs.—The Council of the Royal College of Surgeons have just announced their intention to appoint a Board for the examination of candidates in midwifery, to consist of two gentlemen selected either from the Royal College of Physicians or Surgeons (*vide* our Advertising columns).

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 27, 1852:—

Bockett, William Charles.
Ducket, Clark Armstone, Quadring Eaudike, Lincoln.
Edmunds, John, Bangorwood, Flintshire.
Hancock, John, Wolstenholme, Bolton-le-Moors.
Harris, Charles, Northiam, Sussex.
Yelf, Leonard Keatley, Ryde, Isle of Wight.

3rd June:—

Ellery, Henry James, Truro, Cornwall.
Kingsford, Charles Dudley, Wellington-st., Southwark.
Lawrence, Benjamin Richard, Cheddar, Somerset.
Mushet, William Boyd, Coventry.

Obituary.—On the 2nd of April, Dr. Davidson, of the 43rd Regiment of infantry, killed in action with the Caffres. On the 26th ult., at Bideford, North Devon, Henry Charles Boisragon, M.D., late of Cheltenham. On the 4th inst., at Cary House, Torquay, Henry Parkin, M.D., aged 59. On the 1st inst., at Watford, Herts, in the 40th year of his age, John Smith, Esq., surgeon, sincerely regretted by all who knew his private worth and great kindness of heart.

The Capture of Lagos.—Death of Mr. Richard Carpenter, of the Penelope.—Those who have read the despatches of Commodore Bruce, relating to the bombardment of Lagos, on the West Coast of Africa, may remember the enlogistic testimony borne by that Commander to the members of the Medical Profession engaged in the action, for their skill and gallantry in rendering succour to the wounded, under circumstances of more than usual danger; many of them having accompanied the boats exposed to the hottest fire of the enemy. Foremost among the names so honourably distinguished was that of Richard Carpenter, of the Penelope, who, being the senior surgeon of the expedition, might have remained in his ship, and avoided danger. Preferring, however, honour to safety, he volunteered for the fight, and was in the boat of the Teazer, in which 14 were killed and 62 wounded, many of the latter to die soon afterwards. We have this day the painful duty to record his death. Having braved the malaria of the West Coast on a former commission, he sank under a second and more severe trial; and the tenement of his noble spirit has been lowered into the deep. As surgeon, or as messmate, his frank and generous bearing won for him the esteem and love of all with whom he sailed; nor was he less a favourite on shore, as he can tell who writes these lines. Peace be with him. He died homeward bound, May the 5th, aged 44, having served his country upwards of twenty years.

University of Cambridge.—At a congregation of this University, held lately, H. J. Haviland, of Pembroke College, and Robert Martin, of Caius College, were admitted as licentiates in medicine.

University of London.—Sir R. Inglis, in the House of Commons the other night, said that the University of London was "worse than sectarian, for it was nothingarian. (A laugh.)" And thus a clever and learned man seeks to run down a university by a bad joke, because, erected for the advancement of science, it does not, like the older universities, exclude Dissenters, etc., from its honours and dignities. *Proh pudor!*

Royal Institution.—The meetings of this institution for the present season will close on next Monday, with Dr. J. Conolly's concluding lecture on insanity, in the after-noon, at three o'clock.

Naval Appointments.—Surgeon William Gunn, M.D., (1835), from the Boscawen, 70 Guardship in Ordinary at Chatham, to be Medical Storekeeper at the Victualling-yard, Deptford.

Royal West Middlesex Regiment of Militia.—Nicholas M'Cann, gent., to be surgeon.

St. Mary's Hospital, Paddington.—The Anniversary Festival of this Charity was held recently, at the London Tavern, the Earl of Carlisle in the chair. The noble Chairman strongly advocated the claims of the hospital for public support. At present, only 120 beds are in use. The sum required annually for 150 is 4,400*l*. 725 in-patients have been admitted since the opening, and 1985 out-patients; 1087 casual cases, 228 poor married women attended at their own homes, and making altogether between 4000 and 5000 who have received relief from the hospital officers. The present certain income annually is only 1613*l*.; the balance at the

banker's is 1688*l.*; a debt of 3500*l.* being still owing for the building expenses, and 300*l.* more are required to clear off the debt for furnishing. The sum subscribed in the course of the evening amounted to 3300*l.*

St. Thomas's Hospital.—On Friday, May 21st, a public meeting of the students of this hospital was held in the large theatre, at one o'clock, for the purpose of presenting Mr. Rainey, the able and talented Senior Demonstrator of Anatomy, with a testimonial indicative of their regard for his private worth, and the zeal at all times displayed by him in imparting instruction to his pupils. Mr. Simon kindly took the chair; and Mr. Carpenter, the senior house-surgeon, in an eloquent and effective speech, presented Mr. Rainey, on behalf of the subscribers, with one of Ross's finest microscopes. Mr. Rainey—who seemed to be much affected by the kindness displayed towards him—replied, in a touching speech, which was much applauded throughout, thanking them for the honour they had done him by the presentation of such a valuable testimonial. He also thanked Mr. Carpenter for the kind allusions he had made, and concluded by hoping, that the testimonial would be a fresh incentive to him for arduous study, and trusted that he should see all his pupils, wherever they might be, enjoying prosperity and happiness. Votes of thanks to Mr. Lankester, the senior prizeman of the third year, for originating the idea of the testimonial, and to Mr. Simon, for his kindness in taking the chair, were carried by acclamation.

Western Dispensary for Diseases of the Skin.—A public meeting of the subscribers to this Institution was held at the Dispensary, 21, Goodge-street, on Monday, the 7th inst., for the purpose of receiving the first Half-yearly Report of the Committee; the Rev. Thomas Dale, M.A., Vicar of St. Pancras, President of the Institution, in the chair. The Report, which was read by the Secretary, stated, that, during the last six months, 122 patients had been entered on the books, and 47 had been discharged cured; the greater proportion of the remainder being still under treatment, having received much benefit; and that no case had as yet been discharged incurable. Resolutions were passed for adopting and publishing the Report, and for according the thanks of the meeting to Mr. Hunt, the surgeon to the Dispensary; and to the Rev. President. Several distinguished members of the Profession were present on the occasion.

Provincial Medical and Surgical Association.—The first annual meeting of the Midland branch was held in Nottingham on the 3rd inst., and was numerously attended. The Chairman, Dr. Williams, of Nottingham, delivered an elaborate and interesting address, in the course of which, after adverting to the talents of his predecessor, Dr. Bent, and explaining the objects of the Association, he took an extended view of the diseases most usually prevalent in Nottingham, its rate of mortality being the highest of any town in England, of the sanitary measures adopted to restore it to a healthy state, and also of the charitable, medical, and scientific institutions in the town. He spoke in the highest terms of Dr. Marshall Hall, whose discoveries, he said, threw a bright lustre upon his native town, of which they might well be proud. In conclusion, he adverted to homœopathy, hydropathy, and other systems of quackery, encouraging his audience to denounce such things as "a mockery, a delusion, and a snare." A vote of thanks to the president was carried unanimously; after which, Mr. J. White read a paper on the Medical Topography of Nottinghamshire; Mr. Simpson, "a description of a tumour in the male breast," etc. In the evening the members dined together, under the presidency of Dr. Williams.

Geological Society.—The following papers will be read at the meeting of this Society on Wednesday evening:—1. On the Silurian Rocks and Auriferous Quartz of the South of Scotland. By R. Harkness, Esq. 2. On Protruded Ludlow Rock at Hagley Park, Herefordshire. By H. E. Strickland, Esq., F.G.S.

Mr. Flower, who has been for twenty-two years surgeon to the P division of police, has received from the officers and men of that section, by the hands of Inspectors Maude and Emmerson, a testimonial of gratitude for his professional services, consisting of a massive silver inkstand, with rich cut glass bottles, a wax taper stand, and a gold pen and holder, all in a handsome morocco and velvet case. On the upper raised edge of the inkstand, is the following inscription:—"Presented to J. S. Flower, Esq., of the P division of Police, as a tribute of respect for his prompt and kind attention on all occasions as their medical officer." On the lower edge are the arms and crest of Mr. Flower, handsomely engraved; with his initials and the date of presentation.

Denmark has lost another great man, a philosopher of European reputation, State-Councillor Professor J. F. Schoul, one of the first botanists of the age. He was in his sixty-fourth year at the time of his decease.

Fees Allowed to Medical Witnesses for Attendance at Assizes and Sessions.—The following Petition has been forwarded to G. Sanders, Esq., M.P., by the Medical Practitioners of Wakefield, for presentation to the House of Commons, and also a Memorial to the Lords of the Treasury, embodying the substance of the same. "To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled. The respectful Petition of the undersigned physicians and surgeons practising in Wakefield and its vicinity in the West Riding of the County of York, sheweth,—That your petitioners are frequently called upon to attend at assizes and sessions, to give evidence in criminal prosecutions. That the questions on which they are required to give evidence, generally involve, not only matters of fact, but also matters of opinion. That to qualify themselves for giving sound opinions on such questions, they are compelled to undergo a long, laborious, and expensive course of study. That the position they occupy as witnesses is one of extreme difficulty and anxiety. That, for the purpose of giving evidence, they are frequently compelled to travel long distances from home, and to be absent from practice for several days consecutively, at considerable personal inconvenience and pecuniary loss. That the fees allowed to medical witnesses for attending at assizes and sessions have been, of late years, reduced from two guineas per diem to one guinea per diem. That the reduced scale of fees barely reimburses a medical man for his necessary expenditure when from home, and leaves him no remuneration for the exercise of his professional knowledge, anxiety, and loss of time. That it is within the knowledge of your petitioners, that on account of this inadequate scale of remuneration, medical men have declined to attend cases in which it was probable that proceedings in a criminal court might ensue, and that they have done this to avoid being subsequently called as witnesses. That occurrences of this nature are likely to prove injurious to the poorer classes of society, and tend to frustrate the ends of justice. That your petitioners beg your honourable House to grant such redress as may seem fit. And your petitioners will, as in duty bound, ever pray. J. G. Wright, Chairman; John Horsfall, Surgeon; J. Bennett, Surgeon; J. G. Atkinson, M.D.; W. Statter, Surgeon; Wilson Beaumont, M.R.C.S.; Thomas Walker, Surgeon; Thomas Ross, Surgeon; William Wood, M.D.; W. R. Milner, Surgeon; E. Walker, Surgeon; Samuel Marshall, Surgeon; E. Walker, Jun., Surgeon; Francis Horsfall, Surgeon; Benjamin Walker, Surgeon; Benjamin Kemp, Surgeon; William Dawson, Surgeon; Samuel Secker, Surgeon; D. B. Kendell, M.B., Cantab.; Henry Dunn, Surgeon; Samuel Holdsworth, M.D.; John Burrell, Surgeon; John Dawson, L.S.A.L.; John James Bird, Surgeon; C. Jewison, Surgeon; R. Craven, M.D.; Wm. W. Kemp, Surgeon; G. F. Naylor, M.R.C.S.; John Hirst, Surgeon; A. Jessop, Surgeon.

A proposal is on foot to establish a General Dispensary in Tiverton, Devonshire.

The Lunacy Act.—On the 6th instant, Mr. Henry Baker, of 21, Doris-street, Lambeth, was summoned before the magistrates at Lambeth Police Court, to answer to a charge preferred against him by the Commissioners in Lunacy, for keeping a house for the reception of lunatics without having been duly licensed. Mr. Campbell, one of the Commissioners, proved searching the defendant's house, under a warrant from the Lord Chancellor, and finding there two lunatic patients, and learning further, that a third patient, then out, was also kept in the house. Mr. Jaffree, surgeon, proved having attended these patients, and that they were all lunatic or idiotic. The Secretary to the Commissioners gave evidence that the house was unlicensed. An appeal *ad misericordiam* was made on the part of the defendant, but was not listened to, and he was bound over to answer the charge at the Central Criminal Court. The offence is considered a misdemeanour in the eye of the law.

Charity for Hospital Purposes.—The Devon and Exeter Hospital has recently had two munificent donations added to its funds—one of 2,000*l.* left by the late Rev. Dr. Troyte, late of Huntsham, and the other by the late Mrs. Halford, of Newcourt, near Exeter, who, after giving specific legacies, amounting to 60,000*l.*, has bequeathed the whole residue of her property to this Institution. It will amount, it is said, to nearly 50,000*l.* 20,000*l.* of this will not be available, however, till the decease of the husband of the testatrix, as he has a life interest in it. Mrs. Halford has also left legacies of 1,000*l.* each to the following Charities:—The Exeter Dispensary, West of England Eye Infirmary, West of England Institution for the Deaf and Dumb, and West of England Institution for the Instruction of the Blind. Mr. Dixon has presented 30*l.* to the Royal Orthopædic Hospital. Among the contributions to its building fund, we find that Mr. Cramp has given 105*l.*, and Messrs. Overend, Gurney, and Co., 50*l.*

PROGRESS OF EPIDEMICS.—The small-pox has begun to abate somewhat in the parish of Trelawny, Jamaica. The advices from the other parishes are more disheartening. There is not a parish in the island, in which, it is feared, the epidemic will not break out. The weather is very sultry, and the want of rain is very severely felt, especially in the country parishes. Horned and other stock have suffered to a large extent, and several deaths have occurred among them in consequence. In Jamaica, the measles have also made their appearance, several cases having been reported from the parishes of St. Anne and Trelawny. In Kingston, also, there have been several cases, and, in many instances, small-pox and measles have attacked the same patient. In general, however, the cases are distinct, and particularly mild. Hooping-cough and measles prevail extensively throughout Barbadoes, but the island is free from other diseases.

DEATHS *in the Metropolis for the week ending Saturday, June 5*, 1852.

TO CORRESPONDENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—A patient of mine applied to me the other day, to know if he might consult the person whose advertisement I enclose. I told him, I certainly could not recommend him to do so as, on reference to the "Medical Directory," I could not find any such name. He then drew my attention to the latter part of the advertisement, purporting to be an endorsement of his qualifications, quoted from your Journal, which rather staggered my previous opinion, as I did not at the moment observe, that the title of your paper is so modified as to mislead any one not of the Profession. A notice of this in your next Number will oblige, I am, &c. D.E.A.F.

Leicester.

[The advertisement forwarded by our correspondent is that of a person professing to cure all kinds of deafness by a novel and curiously rapid process; and, subjoined to the advertisement, is a laudatory notice, said to be extracted from the "*Medical Gazette and Times*." Of course, no such notice appeared in this Journal, and there is no journal of that name in existence.]

HISTORY OF A SPIT. — Translated from the French.

[To the Editor of the Medical Times and Gazette.]

SIR,—I find in the last Number of the *Journal des Connaissances Medico-Chirurgicales*, a very amusing history of a case, narrated by Ricord, at a dinner given by the distinguished surgeon Seutin to his *confrères* of Belgium, and who had, a short time previously, entertained him on his return from Russia. The story is told before a hundred and twenty members of the Faculty, and whether true or fabulous, is well calculated to ridicule a useless, absurd system of interrogation pursued by many practitioners towards their patients:—

"M. X—— made a journey, either by railroad or by steam-boat, I do not recollect exactly by which of those two modes of travelling. At all events, this uncertainty is of little importance to the subject with which we have to occupy ourselves, as you shall immediately see. However, it occurred, the boiler exploded, and M. X—— was transfixed by an iron spit, seven feet long. The spit penetrated his belly a little above the navel, and came out at an opposite point through the back in such a manner, that there were three feet before and three feet behind. M. X—— was brought to his house, and his position was considered one which required the aid of science.

"A doctor was called in. He first began feeling the patient's pulse, and, by way of gaining time, he, (the doctor) wished to do two things together, and therefore, at the same moment, asked him where he suffered. 'In my belly, Sir.' 'Ah, very good! how has this happened to you?' The patient then relates, at full length, the circumstances of the explosion. This account finished, the doctor thinks it his duty to follow up his questions: 'Are your family subject to this accident, Sir?' 'No,' answers the patient, 'for all that I know, they are not. Both my father and mother are very old, and have never been spitted: my brother enjoys the best health, and my sister, in like manner, at no period of her life had a spit run through her belly. I can say the same for my uncles and aunts.' 'Very well, Sir, I wanted all that information for the purpose of forming a prognostic.'

"The doctor, in order to prove to his patient that he completely understood the nature of his complaint, still continues, 'You must find it very difficult to lie upon your back?' 'Oh, yes, Sir, I find it quite impossible.' 'You must experience the same amount of difficulty to lie upon your belly?' 'Indeed, Sir, I have exactly the same difficulty with regard to that position.' 'It ought to be much easier for you to lie upon your side?' 'Upon my word, Sir, it is just so; that is the only position that I can take.' 'Very well, Sir, all this information is sufficient for me; it now only remains to decide upon the mode of treatment. In this case, the indications are very precise indeed. We have to select between these two things,—we can either leave the spit in *statu quo*, or, if possible, pull it out; make up your mind for one or the other.'"

Dieppe. I am, &c. STEPHEN MORIARTY, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your remarks appended to my communication of last week, on the subject of Homœopathy, were certainly sufficiently severe, and also, as it seems to me, quite uncalled for. If I was unfortunate in my illustration of the different kinds of truths, so, also, was Sir J. Herschell in the quotation which I gave, and so is Archbishop Whately equally unfortunate, since they both bear me out in my assertion, that the truths of mathematics and metaphysics may be elicited by *à priori* reasoning, and are not, equally with medicine, founded on experience and experiment. I quite agree with you, that "medicine is to be advanced by experiment and observation," and that "there is no reason why we should not find out a better method of treating rheumatism; and consequently, you cannot, prior to, and independent of experiment, affirm, that this "better method" is not to be found in Homœopathy. As to my ignorance of the foundation of therapeutics, I believe it to be founded on carefully-conducted experiments and observations; and that, being thus founded, Homœopathy has a stronger claim upon our attention than those unknown nostrums which find their way into the wards of our hospitals. Lastly, as to my signature, I need hardly say, that I am fully aware of its derivation, and I employed it simply because I am what is called an Allopath. Why you should find fault with it, I do not know. Requesting the favour of the insertion of these few lines (to which, I think, I am entitled, by way of self-defence),

London. I am, &c. ALLOPATH.

[The question has been settled by experience and observation. The so-called facts of the Homœopaths have been shown over and over again to be no facts. They have been convicted of statistical falsehoods, *usque ad nauseam*.]

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last Number you stated it to be probable that the Hall would make some regulations for the better convenience of middle-aged gentlemen who may be desirous to pass the examination. It would have been well had the authorities thought of the propriety of this before; but "better late than never." Now the College of Physicians are willing, upon the receipt of a certain fee, to give their licence to M.D.'s who are graduates of any British University. Why, then, is it not sufficient for the same graduates to pay, in like manner, a sum of money to the Apothecaries' Company, in order to possess (if they wish it) the privilege simply of administering their own remedies to their own patients? Surely there can be no doubt about the practical capability of these gentlemen.

I am, &c. A GRADUATE OF A BRITISH UNIVERSITY.

Dr. Barclay, of Leicester.—Thanks; the matter shall receive attention.

A Young Surgeon has only to apply to an instrument maker.

WE shall be glad of Mr. Woolcot's occasional Hospital Reports.

Dr. Barker, of Bedford, will observe, that his letter was anticipated.

A St. George's Student.—The discussion is not worth continuing.

If *Juvenis* will address the Secretary of the Society he will receive the information he requires.

Errotum.—In the Report of the Royal Medical and Chirurgical Society, in Dr. Th. Thompson's speech, p. 505, 2nd col., 22nd line from top, for "showed themselves a week afterwards," read "showed themselves ten weeks afterwards."

COMMUNICATIONS have been received from—

Dr. BORCHELL, of the Kingsland-road; Dr. BARCLAY, of Leicester; INQUISITOR; A YOUNG SURGEON; A COUNTY SUPERINTENDENT; Dr. HOLDSWORTH, of Wakefield; Mr. MILTON, of Jewin-street; A CONSTANT READER; ALLOPATH; Dr. SNOW, of Sackville-street; Dr. MORIARTY, of Dieppe; AN EX-SUPERINTENDENT; Dr. BARCLAY, of St. George's Hospital, and May fair; Mr. LANGSTON PARKER, of Birmingham; Mr. WHARTON JONES, of University College, and George-street, Hanover-square; Dr. WILLIAMS, of Swansea; STAFF SURGEON DARTNELL, of Fort Pitt, Chatham; Dr. CRAWFORD, of Montreal; A GRADUATE OF A BRITISH UNIVERSITY; Mr. ROBERTS, of Rye; Professor QUAIN, of University College, and Cavendish-square; Dr. CARR, of Rusholme; Dr. T. K. CHAMBERS, of St. Mary's Hospital, and Hill-street; A ST. GEORGE'S STUDENT; Mr. WOOLCOT, of the Kent Ophthalmic Hospital, Maidstone; Dr. BARKER, of Bedford; Dr. WRIGHT, of Birmingham; Mr. ROBERTSON, of Birmingham; SECRETARIES OF THE EPIDEMIOLOGICAL SOCIETY; Mr. W. SELF, of the Commercial-road; Mr. BOTTOMLEY, of Croydon.

ORIGINAL LECTURES.

LECTURES ON CLINICAL MEDICINE,

DELIVERED AT

The Liverpool Royal Infirmary.

By JAMES TURNBULL, M.D.,

Physician to the Infirmary, and Lecturer on Clinical Medicine to the Medical School.

Case of Aneurism of Abdominal Aorta, in a Patient formerly cured of Popliteal Aneurism by Pressure.—Remarks on Diagnosis.—Treatment.—Case of Tumour in Epigastrium, with Pulsation.—Case of Cancer of Kidney, Lungs, etc.—Post-mortem Examination.—Remarks on Microscopical Appearances.

Gentlemen,—I have observed, that clinical lectures are not intended to supersede the necessity that each of you should examine the cases for yourself; and the two first to which I shall to-day direct your attention, will give you a practical illustration of this observation; they are cases of pulsating tumour in the epigastrium. Both are situated to the left of the median line, about midway between the umbilicus and the cartilages of the false ribs; but, though pulsation can be distinctly felt in both, by the patients as well as by us, we have every reason to believe, that, in the one case, the pulsation is simply communicated from the aorta over which the tumour is seated, while, in the other, it is aneurismal. That, in this case, it is aneurismal, we have strong reason for believing, from the fact of the patient having been formerly cured of popliteal aneurism by pressure over the femoral artery.

ANEURISM OF ABDOMINAL AORTA.

J. R., aged 45, a sailor, native of Jersey, was admitted on the 26th December, with a pulsating tumour in the epigastrium, from which he was suffering great pain. He was rather thin, of sallow, dark complexion. He informed us, that nearly three years ago he perceived a tumour in the popliteal region, which continued to increase during three months, till it was as large as his fist. He then went into Kingston Hospital, Jamaica, where compression was made upon the femoral artery for a week. The pulsation was then gone, and the swelling greatly reduced; and in three days after he was able to take a little exercise. He left the hospital, after having been six weeks in it; and when admitted here, there was scarcely any trace of the tumour remaining, and the artery seemed to be obliterated, as no pulsation could be felt. Four months before he applied for admission here, he began to feel a beating in the epigastrium, and during two months he experienced pain, which gradually became very severe, and was greatly increased by any flatulent distension of the bowels. The impulse is strong and expansive, and gives the sensation of proceeding from a tumour about two inches in length, by one and a-half in width. It is increased by any mental excitement, and is accompanied with a single murmur, which is readily perceived with the stethoscope, but is not remarkably loud or harsh.

The fact of this patient having had aneurism of the popliteal artery would give us a strong reason for presuming, that a pulsating tumour in the course of any other large artery should be of the same nature, for we know that, though aneurisms are often produced by a strain or other injury of the artery, such accidents rarely produce the disease where the artery had been previously sound. The unsound state constituting the predisposition arises from an alteration of the nutrition of the arterial coats, of the nature of fatty, atheromatous, or calcareous degeneration, which impairs their elasticity, and renders the internal and middle coats more easily ruptured. Hence it arises, that several aneurisms are sometimes formed in the same individual, and that, in this case, though one has already been removed by a method of treatment which constitutes one of the greatest triumphs which scientific surgery has gained over the mere use of the knife, and for which we are indebted to the Dublin medical men, we have here a return of the disease in another and more dangerous situation from the original predisposing cause.

In the character of the tumour itself, we have further reason for believing it to be aneurismal. The pulsating part gives the sensation of expansion, and there is no difficulty in ascertaining that the pulsation arises, not from any tumour resting upon the artery, as in the other case to which I shall presently direct your attention, but from the artery itself. By careful examination, we can trace the artery below the enlargement, and there find it of natural size. A single murmur, corresponding with the pulse, can also be distinctly heard, and is confined to the situation of the tumour. In cases of aneurism, a single murmur, corresponding with the contraction of the heart and the dilatation of the vessel and tumour, can generally be heard, and is a valuable aid in the diagnosis of this disease, and in some cases, more particularly of thoracic aneurism, a second and feebler murmur, corresponding to the time of the second sound of the heart, is occasionally heard. The loudness and harshness of the first is chiefly dependent upon the amount of obstruction the current of blood meets with in the seat of disease. The second murmur occurs in those cases of false aneurism, where the sac acts as a reservoir, from which the blood is forced back again into the vessel, producing a feeble murmur in its return through the opening between the vessel and the sac. In some cases, where the aneurisms have become very large, and the coats have been very thick from abundant deposit of fibrinous layers, I have been unable to distinguish any murmur at all, but simply a sensation of shock communicated to the ear.

Again I would remark, that the existence of a murmur in the course of a large artery should not, even when the patient complains much of beating in the part, lead you to believe in the existence of an aneurism, unless you find it combined with the presence of such an expanding tumour of the artery as we find in this case. For you will occasionally meet with thin, nervous, or anæmic individuals in whom very violent pulsation at the epigastrium is complained of, and is much aggravated by any mental emotion, or by the attention being directed to the part, without there being any disease in the vessel itself. Such pulsation is produced by dyspepsia or anæmia, and requires the same tonic and antispasmodic treatment as nervous palpitation of the heart. In these cases you will find that the pressure of the stethoscope upon the vessel often causes a murmur as distinct as that of aneurism. You distinguish such cases from aneurism, however, by the absence of any distinct tumour; by the pulsation being traceable along a considerable portion of the vessel; by the peculiar whiffing murmur being heard in other arteries, especially those of the neck. In many of these cases, too, from the blood being thin and deficient in red globules, you will find that there is a continuous humming murmur in the veins of the neck, such as I have pointed out to you in cases of chlorosis. In the case before us, the patient is of very nervous temperament, so much so that any excitement, or his attention being directed to the part, increases the pulsation. This is much against him, and tends to hasten the advance of the disease; and, if the other signs of aneurism had not been well marked, it might have introduced some difficulty into the diagnosis of the case; but the expanding character of the pulsation, the severe pain in the tumour, as well as in the back, and the previous existence of popliteal aneurism, leave no doubt as to its nature.

The prognosis, in cases of internal aneurism, is extremely unfavourable; but we have reason to believe that there have been instances of recovery from sacculated aneurism of the aorta, in consequence of the blood coagulating and forming firm fibrinous layers in the sac, which has thus become completely obliterated and transformed into a firm fleshy projection attached to the vessel. In treating the disease, we must endeavour to promote this natural method of cure: and, though our hope of success will necessarily be very limited, we know that the means which promote this object are those best calculated to retard the progress of the disease, and to prolong the life of the patient. The formation of fibrinous coagula in the sac, and its contraction, are promoted by all those means which diminish the heart's action and the rapidity of the circulation, and thus favour the stagnation of the blood in the aneurismal sac. Bleeding, low, dry diet, rest, and sedative and astringent remedies, such as digitalis, aconite, acetate of lead, and gallic acid, are the chief means which have been used for this purpose. The deep position of the aorta, and the interposition of important vital organs, will, I fear, prevent us from ever being able to apply pressure in such a manner as to command the circulation in aneurisms of any part of this vessel; but the success which has attended this method of treating those of other parts should stimulate us to make more dili-

gent and persevering use of the other means which lessen the force of the circulation.

This patient being a man of very spare habit and highly nervous temperament, I have not thought it advisable to push depletion and low diet to an extreme degree, lest reaction might be induced. The beneficial effects of moderate depletion, rest, and restricted regimen, have, however, been so marked, that we are encouraged to persevere in this plan of treatment. He had first a few leeches applied to the tumour, which relieved the pain considerably. He took thrice a day a pill containing two grains of acetate of lead, one grain of digitalis, and two of extract of hyoscyamus. Compound decoction of aloes was used occasionally to obviate the constipation produced by the pills; but great inconvenience resulting from this, the pills were laid aside, and on the 4th of January about six ounces of blood were taken from the arm. From this he experienced the greatest relief, the pulsation and pain were very much lessened, and the murmur became comparatively faint. On the 12th he had pain extending towards the groin, and leeches were again applied. After this, he took an eighth of a grain of the extract of aconite in pill with digitalis and hyoscyamus thrice a day, by which the pulsation and pain were decidedly relieved. On the 22nd of February he was again bled to the extent of six ounces, and the blood was buffed. Though very much weakened, the patient was fully reconciled to this treatment by the decided diminution it produced in the pulsation and pain; and we shall still endeavour to carry out the indications of treatment I have laid down, controlling as much as possible the force of the circulation, and diminishing the quantity of fluid in the vessels, whilst we seek to avoid, on the other hand, reaction, and such impoverishing of the blood as would reduce its tendency to coagulate in the sac.(a)

TUMOUR IN EPIGASTRIUM WITH PULSATION.

A. C., a tall, pale, emaciated woman, aged 49, was admitted on the 8th of January. The catamenia are still regular, and she is mother of four children, the youngest of which, if alive, would be two years of age. About two years ago, she felt a small swelling in the epigastrium, which has gradually increased, and she thinks that a blow during her last pregnancy may have caused it. The tumour is not felt in the situation of the pylorus, but to the left of the median line, and it extends upwards, slightly below the cartilages of the false ribs. It is hard, flattened in shape, and has a nodular projection about the centre. The patient has severe burning pain in it, which extends towards the back, but there is no tenderness when it is examined. She complains of a beating in it, and the pulsation can be readily felt on applying the hand. It is not, however, the strong expanding pulsation which we have in the last case; and from this circumstance, as well as from the hard flattened shape of the tumour, we can have no doubt that it is simply communicated to the tumour from the aorta, over which it is situated. The patient has occasionally had sickness and vomiting, and the appetite is bad. The tongue is pale and clean, and smoother than natural. She had been confined to bed for five weeks, and had not slept for several nights before admission, from the severity of the pain. A draught containing half a grain of the acetate of morphia has been given every night, and from this she has had sleep, and has experienced the greatest relief.

In inquiring into the nature of the disease, and the organ affected, we must remember, that the stomach, the spleen, and the pancreas, are those which occupy the situation of this tumour, and one of these is, therefore, most probably the seat of the disease. The stomach is far more frequently affected with malignant disease than either of these organs; but, as the tumour is in the left side of the epigastrium, and there has been very little vomiting or gastric disturbance, I have thought it not improbable, from its position, that the spleen might be affected. As to the nature of the disease, there can be no doubt, from the pain and hardness of the tumour, from the age of the patient, and from her weakness and emaciation, that it is of malignant scirrhous nature. Our treatment will therefore be entirely palliative.

ENCEPHALOID CANCER OF KIDNEY, LUNGS, ETC.

I have now to show you the morbid appearances in a rare and curious form of disease—soft cancer, primarily affecting the left kidney, and also the lungs and some other organs. I am sorry I can give you but an imperfect history of the case, as the patient was admitted in the last stage of the disease, suffering extremely from dyspnœa and pain, and could, therefore, give scarcely any account of himself. I had also no opportunity of learning his previous history from his friends.

He was 52 years of age, of intemperate habits; and he stated that he had been ill with jaundice for six weeks; but he had merely the pale, yellowish, straw-coloured tinge of complexion, so common in cases of cancerous disease. He suffered great general distress, and had dyspnœa, cough, and pain in the left side of the chest. On examining the chest, the sound on percussion of the left side posteriorly was found to be generally duller than on the right; respiration was feeble, and mixed with rather large mucous rhonchi. A blister was applied, but the dulness increased so rapidly, while respiration became more feeble and distant, that no doubt could be entertained, that effusion into the pleura had taken place. This was the immediate cause of death; for, on opening the chest, it was found, that numerous white nodules of soft, brain-like cancer, developed in the tissue of the lung, had extended to the pleura, projecting from the surface of the lung, and had caused pleurisy and effusion of a large quantity of serum mixed with lymph. You observe, that, throughout the substance of the lung, there are numerous soft, white nodules, varying from the size of a pea to that of a walnut; and some of those which have reached the surface show a tendency to the cup-like central depression which is often so characteristic of this form of cancer when it attacks the liver. Towards the centre of the lung, there is a large mass of disease, apparently formed by these nodules coalescing; and on cutting into the centre of this, a dark-red appearance is seen. Effusion of blood seems to have taken place into this part, and it illustrates the tendency to hæmorrage in this form of cancer, from which it has been often called, "fungus hæmatodes." The right lung had a few nodules of the same soft, white character, and a few of the bronchial glands were also affected with the disease. The left kidney forms a tumour as large as an ostrich-egg, and is more globular in shape than natural. When cut into, it was found, that the whole of the cortical substance had been destroyed by soft, dirty-white cancerous matter being infiltrated into it at the upper part of the convex border. The tubular portions were not, however, destroyed to any great extent. The disease was much softer than in the lung, and readily broke down into a semi-fluid pulp; from which, as well as from its being deposited in the infiltrated form, it would seem that the kidney had been the primary seat of disease. The left kidney was sound, and also the mesenteric glands, the pancreas, and the spleen; but in the liver, a few small spots of commencing disease were discovered on the surface of the organ.

The cancerous nature of the disease in this case is sufficiently marked to require no assistance beyond simple inspection, to determine its nature; but you have here an opportunity of seeing under the microscope the nucleated cells which have been considered characteristic of cancer. There are three forms of this disease, in all of which such cells are infiltrated among the meshes of a fibrous stroma, and from any of the forms of cancerous growth a viscid fluid, containing the cells, with numerous granules and molecules, may be pressed out. Dr. Bennett considers that the fibres, the cells, and the viscous fluid, constitute the three essential elements of a cancerous growth, the relative amount of these determining its peculiar form, so that, if the fibrous element be in excess, it constitutes schirrus, or hard cancer; if the cells be numerous, encephaloma, or the soft cancer before us; and, if the fluid abound, and be collected in loculi or little cysts, it is the colloid cancer. The appearance of the cells in the diseased structures taken from the lungs and the kidney, are very similar. Some are oval or rounded, others caudate or spindle-shaped, or split into a triangular form.

(a) He was bled a third time on the 3rd of April with benefit, but towards the end of the month the size of the tumour and pulsation were again rapidly increasing. From the 24th of April, therefore, to this date (10th of May) he has been upon very low diet—three ounces of porridge for breakfast, two ounces of broth and two of bread for dinner, and two ounces of porridge for supper. He has been strictly charged to abstain from any other fluid, and has taken half a grain of morphia every night. Under this treatment, very decided improvement has taken place, he is free from all pain, the pulse is 70, small, the size of the tumour is very materially reduced, and the pulsation greatly lessened in force. We are, therefore, encouraged to persevere. The *Dublin Medical Press* (February 11, 1852) contains a valuable paper, by Dr. O. B. Bellingham, "On the Curative Treatment of Aneurism of the Aorta," in which the use of very low, dry diet is particularly enforced.

They contain from one to three nuclei, each of which has one or two nucleoli; and within the cell there are also numerous granules and molecules. The cells appear to be undergoing rapid development, and to be multiplying by endogenous growth, each nucleus expanding into a fresh cell. Compound granular corpuscles, with numerous granules and molecules, are also visible in the fluid around the cells. In such a well-marked case as this, the diagnosis is sufficiently easy and certain without microscopic aid; but it may be asked if there be any microscopic appearances characteristic of cancer. I believe that cells having the appearances of rapid growth, such as I have now described, are the most characteristic appearances. Dr. Bennett appears to think, that no single element is diagnostic. He observes, however, "when, on the other hand, corpuscles such as I have previously described under the name of 'cancer cells,' are infiltrated among the meshes of a fibrous structure, in the same manner that pus cells are so infiltrated in a pneumonic lung; when such infiltration is not directly connected with a mucous or epidermic surface, and nowhere surrounded by a hyaline or fibro-hyaline substance, then we may conclude, with tolerable certainty, that the structure is cancerous." It would therefore seem, that as yet we cannot do more than regard the microscope as a rather imperfect aid to the diagnosis of the more doubtful cases of cancer, as there is still a numerous class, which even this practised observer has not been able to consider as either decidedly cancerous, or to separate them entirely from such diseases, and to which he has therefore given the provisional name of "cancroid."

LECTURE IN CLINICAL SURGERY,

AT

Guy's Hospital.

By BRANSBY B. COOPER, Esq., F.R.S.,
Senior Surgeon to, and Lecturer on Surgery at, Guy's Hospital.

(Continued from page 511.)

HYDROCELE.

The next variety of hydrocele of which I shall treat is that termed congenital hydrocele. Some time ago I had a well-marked case of this kind. A gentleman came to me with swelling of the scrotum, exactly resembling in every respect common hydrocele, being smooth, quite transparent and fluctuating. Presenting the signs of hydrocele so unequivocally, I recommended the patient to have the tumour immediately tapped; he consented, and I was about to perform the operation, when, upon seizing the scrotum, to render it sufficiently tense to be easily pierced by the trocar, the fluid seemed to escape from under my hand. Upon increasing and maintaining the pressure, the fluid passed out of the scrotum into the abdomen, and I immediately perceived that this was a congenital hydrocele. Instead, therefore, of merely tapping it, as I had intended at first, I drew off the fluid, and then applied a truss, and, in a short time, the patient was quite cured. The rationale of this treatment I shall explain presently. A congenital hernia can only exist in consequence of a peculiar abnormal state of the parts involved in the complaint; in common hydrocele the collection of fluid takes place within that sac which descends with the testicle as a process of the peritonæum, and is afterwards cut off from connexion with the abdomen, by the obliteration of the narrow canal, which at first forms a communication between it and the cavity of the peritonæum; in congenital hydrocele the communication between the abdomen and the tunica vaginalis remains open; and, although it is generally very narrow, not, perhaps, larger than a straw, it is still sufficient to afford a passage for the fluid from the abdomen into the tunica vaginalis. This congenital state of the parts does not imply that hydrocele must be necessarily present; it is not improbable, that such a malformation exists in numerous cases in which fluid never collects in the tunic, and in which, consequently, the communication between it and the peritonæum remains undiscovered. It is clear, however, that such a state of the parts must always render an individual liable to fluid collecting in the tunica vaginalis; and this liability is the greater, inasmuch as it may not only form, in consequence of the tunic itself becoming capable of pouring out an excess of serum, as in common hydrocele; but when there exists a tendency to ascites, the fluid may descend from the abdomen and simply, by virtue of its gravity, occupy the tunica vaginalis, which is the lowest part of the cavity in the peculiar condition I have described; under such circumstances a congenital hydrocele is at once established. In these cases we have no means of knowing whether the fluid is secreted by the tunica vaginalis, or whether it descend from the abdomen, unless we may, to a certain extent, judge the latter to be the case, when we perceive in the patient indications of ascites; it would then, perhaps, be fair to judge, that the fluid had been secreted within the abdomen; this is not, however, a point of much importance with reference to the hydrocele; it may affect the general constitutional treatment, but could make no difference as to that of the hydrocele itself; it very often happens, that after obliteration of the communication between the abdomen and the tunica vaginalis, the fluid becomes absorbed spontaneously, it may be inferred, I think, in such cases, that the fluid had not been originally secreted by the tunic, but had merely descended from the abdomen.

The tumour in congenital hydrocele resembles, in most respects, that in common hydrocele. It is pyramidal in form, smooth and fluctuating, possesses the transparency of ordinary hydrocele, and is about similar to it in size and weight. There is, however, one very important difference: if the pressure of the hand on the tumour be continued, the fluid will be forced upwards into the abdomen, escaping from the tunica vaginalis, through the narrow canal by which the tunic communicates with the cavity of the abdomen, as I have already described. The fluid being thus expressed from the tunica vaginalis, the hydrocele will necessarily become flaccid, losing both its previous form and size. It is said, that, in congenital hydrocele, the size of the tumour is greater at the end of the day than when the patient first rises in the morning.

This kind of hydrocele differs from common hydrocele in another respect. Owing to its being continuous with the cavity of the abdomen, it receives an impulse when the patient coughs, while, in common hydrocele, as the tumour is quite isolated from the abdomen, coughing produces little or no effect in it. The diagnosis of congenital hydrocele is made easy under ordinary circumstances, by the facility with which the fluid may be forced out of the swelling by pressure, and by the tumour not terminating so definitely as a common hydrocele at its upper portion. It may, however, be mistaken for hernia, in which, in like manner, the contents may be pressed out of the tumour by handling, and which receives an impulse from the parietes of the abdomen when the patient coughs. It must be obvious, that the treatment in congenital hydrocele must be very different to that in the common hydrocele. The best mode of treatment is first to draw off the fluid, then to apply pressure upon the external abdominal ring to cause adhesion between the walls of the canal through which the tunica vaginalis communicates with the abdomen. If this can be effected, the congenital is at once brought into the state of ordinary hydrocele, and may be subjected to exactly the same treatment. Constitutional as well as mechanical treatment must be adopted, with the object of correcting the tendency to the formation of a fresh collection of fluid after the first quantity is drawn off. The pressure upon the ring is best made by a truss; but it is clear, that any contrivance which permits of the application of continuous pressure would answer equally well with a truss. Under any circumstances, I cannot think it right to attempt the radical cure of congenital hydrocele by injection; that is to say, so long as it remains in its congenital form. I should never venture to inject such a hydrocele, or to use any other local means for its radical cure; for I think that any treatment which would excite inflammation in the tunic would be attended with great danger, owing to the impossibility of confining the inflammation to the scrotum. Many of the French surgeons take, however, a different view of the subject, and do not hesitate to inject congenital hydrocele, only taking the precaution to press firmly upon the ring during the time the irritating fluid is being thrown into the tunic, to prevent it from passing into the abdomen. After all, this must, I think, be a dangerous experiment; for although, by mechanical pressure, it is perhaps not difficult to keep the fluid itself out of the cavity of the peritonæum, pressure on the ring would prove a very ineffectual means of keeping the inflammation from extending from the tunica vaginalis to the peritonæum, which is, after all, the whole source of the danger. Independently of the danger, there is another argument against injecting a con-

genital hydrocele: it is quite unnecessary to run the risk, for in almost all such cases the connexion between the scrotum and the peritonæum is easily obliterated when pressure is applied after the fluid has been drawn off in the common way. After adhesion has been produced in the canal, the fluid in the tunic is sometimes absorbed spontaneously; this may be promoted by the application of lotions, and in young subjects by acupuncturation in the scrotum. Occasionally, congenital hydrocele may be spontaneously converted into common hydrocele, owing to the irritation excited by the presence of the fluid in the tunic, producing adhesive inflammation at the point where the cavities communicate, when, in consequence, complete obliteration of the point of communication ensues.

Congenital hydrocele is very common in newly-born infants. The only treatment required is to press the fluid back into the abdomen, apply a slight compress upon the external ring, and keep the scrotum constantly wetted with a stimulating lotion. In children, this treatment will seldom fail to produce obliteration of the communication between the scrotum and abdomen, which will be followed by absorption of the fluid in the tunica vaginalis; indeed, this is generally effectual up to the period of puberty.

I have stated before, that the condition of the parts which leads to congenital hydrocele, may exist without any accumulation of fluid taking place; but such a person is always subject to these accumulations, and at whatever period of life they may occur, the disease is still termed congenital.

It is not always easy to diagnose a tumour in the scrotum, as a congenital hydrocele, as it is not uncommon for intestine to protrude into the narrowed neck of the tunica vaginalis, at the internal ring, so as to prevent the fluid from passing back into the abdomen. There is, however, another diagnostic mark in congenital hydrocele, which it is useful to remember,—the testicle is generally placed quite at the lower part of the tumour, which makes it appear as if a smaller tumour were superadded to the chief mass. If the tumour be transparent, the testicle may be seen lying below the collection of fluid.

Congenital hydrocele is very likely to be complicated with congenital hernia, and every precaution must be taken in ascertaining the presence or absence of hernia, before a truss is applied; if intestine be discovered protruding at the internal ring, it must be returned into the cavity of the abdomen, the fluid then evacuated from the tunica vaginalis, and a truss applied, this will tend equally to produce the cure of the hydrocele and the hernia as far as relates to the congenital form, for the hernia cannot return if the communication be obliterated; and should the hydrocele recur, it would only be in the common form, and not congenital.

Hydrocele of the spermatic chord is a variety of hydrocele in which the tumour extends from the scrotum through the external as high up as the internal ring, giving to the swelling a sort of hour-glass form, in consequence of its being constricted by the external ring. This variety of hydrocele is produced by the obliteration of the communication being limited, not extending, as it usually does, from the internal to the external ring. The tumour itself takes its elongated form, owing to the fluid extending into and filling the tunica vaginalis of the chord as well as that of the testicle. In these cases, after the fluid has been drawn off in the usual way, the sac should not be injected until it has been ascertained beyond question, that hernia is not concomitant with the hydrocele; for, as I have explained, a hernia may prevent the fluid from passing up into the abdomen, even if the hydrocele be congenital. Therefore, before the injection is employed, we ought to learn satisfactorily, that the canal between the serous cavities of the scrotum and abdomen is sealed by permanent adhesion.

In 1841, Mr. H., a gentleman from Norfolk, aged 37, consulted me with a swelling of the scrotum, which had every sign of common hydrocele, with the exception that the apex of the pyramidal tumour extended through the external up to the internal ring. The tumour was perfectly transparent, and the testicle was in the usual position. I at first thought it was a congenital hydrocele; but was not able to press the fluid into the abdomen. I therefore tapped the hydrocele, and then examined for the purpose of discovering whether there was any hernial protrusion through the internal ring; finding no protrusion whatever, I recognised the case as a complication of the common hydrocele of the tunica vaginalis testis and chord. I injected it at once with the solution of iodine. The patient was perfectly cured.

Hydrocele of the chord alone is another variety of hydrocele; in this the fluid is contained within the serous sac of the chord, and not in the tunica vaginalis testis.

A short time ago, one of my dressers drew my attention to a patient who had come into the surgery for relief. He had a tumour in the scrotum, between the testicle and external ring; the testicle being in no way implicated with the swelling. The tumour was about the size of a bantam's egg, nearly incompressible; offering, therefore, but very indistinct fluctuation; no transparency could be perceived; it was quite unattached to the skin, which moved freely over it; and I felt assured, that the tumour contained fluid, and, as the man stated that he had received a blow, I had some suspicion of its being chronic abscess. I punctured the tumour, and let out about half an ounce of serum of the usual appearance of hydrocele fluid, straw-coloured and coagulable; it contained no spermatozoa, proving it to be hydrocele of the chord. I enlarged my opening, passed my little finger into the tunic, and felt that the sac was completely closed, both towards the external ring and the tunica vaginalis of the testicle. The sac became obliterated, and the patient got well.

This tumour must necessarily have resulted from a peculiar obstruction of the tunica vaginalis of the chord at different points of its course, isolating the fluid both from the testicle and the inguinal canal.

We find, therefore, that the accumulation of fluid may take place in the scrotum, between the testicle and the external ring, as in the case just read, or in the inguinal canal between the two rings; in either case, the diagnosis is more difficult than in common hydrocele; the form of the tumour is different, being round instead of pyramidal; it is also generally smaller, and its comparative weight is less; the fluctuation is often very indistinct, and the transparency altogether absent, in consequence of the small quantity of fluid in the tumour not producing sufficient attenuation of the involved tunics. Indeed, the physical indications of hydrocele upon which we generally rely, are, in these cases, very indistinct; at the same time, I believe that an experienced surgeon will possess sufficient tact to enable him to form a correct diagnosis, without much difficulty, as to the presence of fluid in the tumour; but it is, I think, almost impossible to ascertain whether the fluid be placed within or without the serous sac. In the latter case, the tumour comes under the denomination of encysted hydrocele,—a form of the disease which, properly speaking, has nothing whatever to do with the pathology of serous cavities, and which will hereafter be described.

When hydrocele of the chord is situated between the external ring and the testicle, it forms a small rounded tumour, perfectly isolated from the parietes of the abdomen, and on that account, upon proper examination, it cannot be mistaken for a hernia. It is tense, and cannot be emptied by pressure; nor does its form alter by change of position; therefore, it cannot be varicocele; and, though the regularity of its surface, added to fluctuation, will lead the surgeon to infer, that it is neither a fibrous nor a fatty tumour, at the same time, it should be known, that the last point is not always to be determined without difficulty.

Mr. G., of Wisbeach, aged 42, consulted me in April last, being the subject of a tumour in the scrotum, of which he gave the following account:—Twenty years before, in jumping on a horse's back, he injured the scrotum, and very soon after perceived a slight swelling, which gradually increased in size, and seemed to him, as he said, like a third testicle. It had latterly become enlarged, and given him pain; it had acquired the size of a pullet's egg. Upon examination, my first impression was, that the tumour was omental hernia; but, upon closer investigation, I found it quite isolated from the cavity of the abdomen. I then suspected it to be encysted hydrocele, or hydrocele of the chord; but the absence of fluctuation and transparency, and a peculiar sensation of general solidity in the tumour, rendered the diagnosis to me so inexplicable, that I sent the patient to Sir Benjamin Brodie, who wrote me word, that he believed it to be either a steatoma or a fibrous tumour, and referred me to his "Lectures on Pathology and Surgery," (p. 271,) where he relates a similar case. The patient now told me, that he had already consulted Mr. Lawrence, who, it seems, had formed a just diagnosis, as he had told the patient that it was a swelling which must be cut out. I therefore recom-

mended him to return to Mr. Lawrence; but, from what I have heard, I believe the operation has never been performed,—consequently, the case remains still involved in mystery. Is it not possible, that this may have been originally a case of hæmatocele, in which the fibrin had become organized, and adherent to the tunica vaginalis,—a possible condition, as proved by a preparation of John Hunter's, in the Museum of the College of Surgeons?

Having ascertained that the enlargement is not caused by any of the diseased conditions mentioned above, we shall perceive, that the presumption must be, that it is hydrocele of the chord, either external or internal to the tunica vaginalis of the chord. Which of these varieties it is, can only be proved by examining the fluid after evacuation. So much difference will be found between the fluid from the two kinds of hydrocele, that the diagnosis may be at once established with ease from this circumstance.

Within the last week, a patient, between 20 and 30 years of age, came into the hospital with a tumour in the scrotum of rather a doubtful character. Sometime before, he had received a blow upon the scrotum, and the tumour began to form soon after the injury; it was placed on the anterior part of the scrotum, between the testicle and the external ring; it was round, very circumscribed, and so tense, as not to give the diagnostic fluctuation. With difficulty and careful examination, it was discovered to be transparent, although not to a great extent. I considered it to be encysted hydrocele. I tapped it, and evacuated yellow serous fluid, like that of ordinary hydrocele; this fluid did not contain spermatozoa, which, with its general character, abundantly proved to my mind, that the disease was hydrocele of the chord. When I speak of encysted hydrocele, my reason for coming to this conclusion will be more apparent.

[To be continued.]

ORIGINAL COMMUNICATIONS.

ON THE TREATMENT OF CROUP BY WARM VAPOUR AND EMETICS.

By WILLIAM BUDD, M.D.,
Physician to the Bristol Royal Infirmary.

Before passing to the more special object of this morning's lecture, which is to lay before you the results we have recently obtained from the employment of warm vapour and emetics in the treatment of croup, it will be well to call your attention to some cardinal points in the morbid anatomy and pathology of the disease. The admission into our wards of six cases of croup, within a comparatively short period, has given us ample opportunities for studying its phenomena, both in the living and the dead body.

You will see, from an inspection of the specimens before you, which were taken from two of our fatal cases, that the morbid anatomy of the primary element of croup is very simple.

In both specimens, a concrete, dirty-white exudation lines the windpipe from the epiglottis downwards, covering the cordæ-vocales, blocking up the sacculus laryngis, and forming a tough, continuous, tubular membrane. In passing down the windpipe, it becomes gradually less and less tenacious, until it at length passes into mere mucus, a little above the bifurcation of the air-tube. It is important to observe that, in the same direction, the false membrane becomes less and less adherent to the surface on which it lies. In the lower part of the trachea, in these specimens, it floats loose and detached, while, in the larynx, it adheres so closely that it cannot be stripped off entire. So that, by a sad fatality, the morbid product is the harder to dislodge, the narrower the channel it serves to obstruct. This is, I believe, always so; and the fact is one, I need scarcely say, of very great importance in many ways.

Pursuing your examination, you will trace the same false membrane extending by direct continuity over the fauces and velum, and passing thence into the posterior nares. These are its limits in the specimens before you. But cases occur, not unfrequently, in which it extends, by direct continuity also, on the one hand down the gullet to the cardiac orifice of the stomach, and, on the other, into the minutest ramifications of the air-tubes. In an opposite extreme it is sometimes limited to the larynx, itself, covering scarcely more than a square inch of membrane.

Although identical in nature, the morbid product is apt to vary in extent, therefore, in different cases. Dr. West has remarked, that "the false membrane is much oftener found in the larynx than in the trachea, and that it is in both much more frequent than in the bronchi." My own experience entirely coincides with his. The membrane would appear to be first formed in the fauces and larynx, and only to be developed on the remainder of this wide mucous tract by extension of the morbid process. It is a singular circumstance, and one which could not fail to be of great interest, could we see its true significance, that, when the disease penetrates to the lung, it often affects the tubes of the right lung exclusively, the false membrane passing down the right bronchus, and leaving the left untouched.

The histological and other characters of the exudation itself are very important. If you examine a portion of the false membrane under the microscope, you will see that it is essentially made up of cells or corpuscles lying in a granular blastema. These cells bear, as you will remark, a very close resemblance to the common pus-corpuscle. Pus-corpuscles are, in fact, as I have endeavoured to show you at greater length elsewhere, none other than these same cells, dead,—most probably in a higher state of oxidation, and otherwise chemically altered. Here and there, however, a stray cell is seen, marking by its fusiform shape a tendency to rudimentary but abortive development.

The most important character of the blastema in which the corpuscles are imbedded, is the large number of fat-granules it contains. The presence of this large quantity of fat in the morbid product, besides presenting another point in common with pus, is probably connected in some way with its low capacity for organisation.

These characteristics are constant in the false membrane of croup. They are also occasionally met with in inflammatory exudations from other surfaces; especially in such as occur under direct exposure to air, or as the effect of malignant poisons,—or, in weak and cachectic persons, whatever the cause of the inflammation. Such exudations have, in fact, received the epithet *croupal*, in testimony of this likeness to the croupal type.

As a group, they are especially characterised by a proneness to degenerate into pus, and other kindred fluid products, with a tendency to the development of corrosive, and, in some cases, of still more noxious qualities.

This close affinity of the exudation to pus is, in croup, a character of great moment; since, in virtue of it, a product which was, at first, solid and adherent, and firmly choking up the air-channel, may, by a slight change of conditions, give place to a fluid secretion, offering no serious mechanical obstacle to the ingress of air, or to its own expulsion. In cases of recovery, some such secretion always supersedes the croupal, and is, in fact, the chief instrument of that separation from the surface beneath which prepares the way for its ejection.

The condition of the mucous membrane itself varies much in different cases, and in different stages of the disease. As a general rule, it presents less vascular redness than is seen in other forms of inflammation of the same degree. Of this, two different explanations have been offered. One, that the gorged capillaries are relieved from their distension by the outpouring of the effused lymph; the other, that they are choked up with white products of the same nature as the exudation itself. Which of these explanations is the true one, or whether either adequately represents the fact, I will not pretend to decide.

Besides being inflamed, the larynx and under surface of the epiglottis are generally found fretted and ulcerated, and a similar but still more extensive destruction of substance often affects the tonsils also. These alterations are, in great part, the result of the corrosive action of the morbid product. The material of the false membrane is no sooner poured out than it becomes the seat of catalytic changes, which being communicated to the living membrane, (whose power of resistance is lowered by disease, and whose elements are already prone to dissolution,) lead to its disintegration. Direct exposure to air, the presence of sufficient moisture, and the heat of the underlying, diseased surface, all concur to give activity to these chemical changes in the morbid product.

So much, then, for the local changes in croup. If you consider their very definite character, as well as their limit-

ation to a particular tract, you will see at once that we have to deal with a disease of a very special nature. The almost exclusive occurrence of this form of croup in very early life, and, still more, its occasional epidemic prevalence, are facts which admit no other view.

Bearing this in mind, you will not, therefore, take every case of catarrh which may happen to be attended with croupal hoarseness, to be a case of genuine croup, and still less will you confound with the disease before you, that equally specific form of inflammation of the same surface which frequently occurs in the adult, under the name of croup, and which is, in fact, nothing more than erysipelas affecting a mucous membrane.

I draw your attention to these distinctions, not only because they are important to prognosis, but because a knowledge of them is essential to the appreciation of the effects of treatment in any given case.

After this account of its morbid anatomy, it is almost superfluous to add, that this disease of the windpipe is one which derives almost all its importance from situation. As a disease of a mucous membrane, it is often trivial enough; but, as mechanically hindering the ingress of that wonderful agent which quickens the flesh with living powers, croup extinguishes life in its very source.

The mode in which death is brought about, is painfully interesting to watch. In the language of technical writers, it occurs by asphyxia.

Dr. Watson has well shown, in his admirable Lectures on the Practice of Physic, how peculiarly inappropriate is this term as a physiological representation of the event. The word "apnœa," which this eminent physician has proposed to substitute for it, is a far more correct expression. I would, however, venture to suggest, "*death by privation of oxygen*," as better still. Better, not only as more strictly expressing the real fact of the matter, but as bringing before the mind relations which, since they play the fundamental part in the train of morbid phenomena, it cannot be unimportant to keep distinctly in view.

The word "apnœa," (meaning want of breath,) does, indeed, give, in a single word, a vivid and faithful picture of the real manner of the death. But, in concentrating the attention on the difficulty of breathing, as expressed in the vague character of an undefined natural want, however primary, it has the disadvantage of diverting the mind from the deeper relations which this want at once conceals and implies.

Absorbed, indeed, as we are in contemplating the agonies of the slowly-suffocating man, we are already too apt to forget, that this sore distress—these livid and ghastly looks—this conflict—this gasping for life—this despair—this restless agony, only ending in death—that these phenomena, at once so subtle and various, are all the effect of the privation of a common chemical agent.

The fact is one which you would do well to weigh in all its bearings.

Were there no other evidence to the same effect, we might learn from what we witness here, how profound, how manifold, how fundamental a part is played by chemical change in the phenomena of life, in disease, as in health.

What this fundamental relation of oxygen to the living forces implies as to their own nature—their relation to other forces better known to us, or their own several identity (as to ultimate essence) among themselves, we must not now inquire. (a)

It is sufficient, for our present object, to bear in mind the very elementary truth, that the gaseous fluid which finds its only (adequate) entrance into the living economy through the tube which is here all but closed against it, is essential to the development of the powers of life, and absolutely necessary to their maintenance from one moment to another. And that, not vaguely be it remembered, but under quantitative conditions, as rigorous and precise as those which govern the development of the forces which animate—so to speak—the galvanic pile and the steam-engine.

(a) In the wide field that lies between the admission of the chemical agent into the blood, and the wonderful nature and variety of the living manifestations which *all* hang upon it, many high problems stand for future investigation. And, although there is much here that must ever remain inscrutable to us—many a mystery, the depths of which we may never fathom—there are many questions, too, which, taking the form of dynamic problems, not only lie strictly within the scope of scientific research; but which it will not do to ignore, if we pretend to any more than the most superficial insight into the functions of life.

At first view, you may, possibly, be inclined to deem such considerations as these foreign to a lecture, of which the special object is to illustrate a point of practice. But the more you dwell upon them, the more I think you will see their eminently practical bearing on all that concerns the physician in the disease before us.

First, as regards the pathology of croup.

In the progressive and all but complete exclusion of oxygen, you have the explanation of that early failure of power and animal heat which we remarked in all our cases, and which is one of the most important characteristics of the disease.

It is a result of this exclusion that fever so soon gives way to collapse, and a hot and burning skin to colliquative sweats. To the same cause may be traced the early-failing pulse, and the rapidly growing weakness.

A clear insight into these relations will show you, at once, how transient in croup is the period for lowering measures, what caution is needed, even in their early use; and how important it is to avoid, in advanced stages of the disease, for emetic or other objects, the employment of depressing agents.

Perhaps no greater error *can* be committed in the treatment of this disease than persevering too long with lowering measures. The whole effort of contending with the impediment which obstructs the breath, falls on the muscular force, and the issue in death or recovery may depend on the strictest care and economy of that feeble remnant of it, which, in obedience to a blind, but irresistible impulse, is still struggling on in the interest of the other powers.

The time during which the struggle for life is maintained in fatal cases, depends much, of course, on the greater or less rapidity with which the air-channel is blocked up, as, also, in some measure, on the degree of muscular power of the patient.

Where the process of occlusion is rapid, a few hours may finish the work.

When the case is more protracted, other changes intervene, which we must not leave unnoticed.

We have hitherto been giving our attention to the influence of this exclusion of air on the forces of life; we have now to notice effects scarcely less remarkable on the distribution of the fluids also.

A knowledge of these is essential to a complete view of the succession of morbid changes, and of the whole mechanism of death.

I have already had many opportunities of showing you, that (in accordance with a law first clearly laid down by Dr. Draper,) the chemical actions to which the blood is subjected in traversing the capillaries, constitute a very important agency in promoting the onward course of this fluid. Whenever, from want of some essential condition, these actions are hindered or suspended, this course is retarded, and congestion ensues.

Concurrent physical changes in the blood giving it a tendency to adhere to the walls of the vessels, have, no doubt, some part in this result: but the suspension of the normal chemical changes constitutes the chief impediment.

Now, if this be true of the circulation generally, it is preeminently true of the circulation of the lung.

Exclude, or limit, the access of oxygen to the blood, and the course of the blood through the capillaries of the lung is at once retarded. Hence, there is never asphyxia without pulmonary congestion.

The amount of this congestion varies much in different cases and in different stages of the disease, and it is not always easy to determine the precise conditions by which it is governed.

As a rule, however, it is greater the slower the process of suffocation, and the greater the vascular fullness of the patient. For these reasons, it is often greater in strong and robust children, who are not only, generally, more plethoric than others, but, with the same amount of laryngeal obstruction, can maintain a longer struggle.

When the local vascular tension has reached a certain height, the more watery part of the blood transudes, the air-tubes become gorged with serous fluids, and, if the congestion be extreme and protracted, and the heart strong, effusion may even take place (as we saw in one of our own cases) into all the serous cavities of the chest. In the particular case referred to in the parenthesis, there was not only fluid in the pleuræ, but even the pericardium contained a considerable quantity. That there may be no ambiguity

about the fact, it may be well to mention, that the child was previously in robust health.

Upon the occurrence of effusion into the air-tubes, there soon ensues more or less extensive collapse of the air-cells beyond, which constitutes another great impediment to the re-admission of air to the lung.

It is scarcely necessary to add, that after these secondary changes have supervened, there is little hope of relief from any measures addressed to the primary disease in the throat. It is in vain to admit air into the windpipe when obstructions lower down bar its access to the vital fluid.

If, in addition to these considerations, you reflect that the false membrane itself sometimes extends into the minutest air-tubes (as we also saw in one of our own cases), and that (in large towns at least), in a certain proportion of the children affected with croup, the lungs are already tuberculous, you will see at once that a given number of deaths must occur, even under the best-devised treatment.

For the same reasons, it is plain enough that in croup, most peculiarly, all remedial measures will be more successful the earlier they are put in force.

As the danger of the case will, *cæteris paribus*, depend much on the degree to which the natural channel for the admission of air is obstructed, it is always a matter of interest to be able to form some estimate of this.

Now, besides what may be gathered from the lividity, the general distress, and other signs, there are two sources of evidence in phenomena the most easy to observe, which, taken together, will always give you a very accurate measure of the degree of obstruction. One is to be found in the modification which occurs in the natural respiratory murmur. Whenever this murmur is extremely feeble, and still more when it is inaudible, we may be pretty sure that the ingress of air is much impeded. But a still more accurate measure of the degree of laryngeal obstruction is to be found in a peculiar modification of the act of breathing, which always occurs in severe cases of croup, but which I do not remember to have seen anywhere noticed.

The first result of the privation of air, however occasioned, is redoubled effort on the part of all the respiratory muscles. The diaphragm descends with great force, and the help of every auxiliary muscle is enlisted in behalf of the distressed organism. The amount of effort is determined by the needs of the economy and the strength of the acting muscles, but the result depends in great part on other conditions. As there is no vacuum possible here, the actual expansion of the chest is measured, not by the respiratory effort, but by the volume of air which can still pass in through the narrowed glottis. So that when, as often happens, the glottis is all but closed, the effect of the utmost effort of the respiratory muscles is not to expand the chest, but merely to alter its form. This is the explanation of that remarkable sinking in of the sternum and sternal cartilages, as indeed of all the lower part of the chest, in the act of inspiration, which occurred in all our fatal cases as the end drew near.

Having detained you so long with considerations on the pathology of croup, we may now pass to the treatment of the disease.

This, it is scarcely necessary to say, embraces two primary and fundamental objects;—the first, to promote the separation and expulsion of such false membrane as may be already formed,—the second, to prevent the formation of new false membrane, by means calculated to moderate or to alter the character of the inflammation to which the morbid product owes its origin.

Now, long before adopting the precise method of treatment applied to the cases I shall presently have to relate, many considerations had led me to suppose, (in common, I doubt not, with many others,) that the most direct as well as most effectual means of securing both objects would probably be found in the suitable modification of the atmosphere breathed by the patient.

On the other hand, it had appeared to me equally clear, on the same grounds, that the great obstacle to the cure of the local disease of the windpipe, is the direct chemical action of the double current of air passing over the inflamed surface.

There is, indeed, much reason to believe, that the effect of air, and specially of the oxygen it contains, in keeping up inflammation, (itself a process of rapid oxidation,) in already diseased parts, as well as in exciting inflammation in parts whose power of resistance to common chemical agency is, through some cause, lowered, is only beginning to be appreciated.

Yet there would seem to be little doubt, not only that this agency of the air is most large and influential, but that a knowledge of it furnishes a principle fertile in applications as well to the cure as to the prevention of disease.

The reality of such an agency as that here assumed, may be made evident in many ways.

In the first place, the consuming and destructive power of the active principle of the air we breathe on living tissue, generally, is universally known. Every day as much of the substance of the living body as is represented by the flesh, and other nitrogenous constituents, we appropriate in the shape of food, is reduced from the living state to that of dead chemical compounds by this consuming agent.

Here the oxygen of the air is, it is true, in solution in the blood, and in dynamic and physiological relation with the tissue with which it unites, but in the gaseous form also, and on the surface of the body,—acting not physiologically now, but pathologically,—its effects under certain conditions are scarcely less marked.

Thus, for instance, to certain forms of serous membrane, especially if to its own power the depressing effect of cold be added, air is most deadly.

Admitted into the pleura, the peritoneum, or arachnoid, (as I once saw in a person in whom the trephine was used for the removal of a piece of scull, which was supposed, through irregularity of form, to be the cause of inveterate epilepsy in the patient,) cold air often excites the most intense inflammation,—a result which there is no reason to doubt is mainly due to the chemical action of the oxygen it contains on the delicate membrane which lines these cavities.

It may, indeed, be objected, that this offers no analogy to the case before us, since the epithelium, which covers the air-tubes, is, not only like that of the surface of the body generally, proof against any injurious action from the air, but is actually destined to protect the underlying tissues from its corroding influence.

This is undeniably true. But, on the other hand, the susceptiblity which this structure does not possess by nature, it may readily, and from various causes, acquire, and to almost as high a degree as that of the serous membranes themselves.

In the state of health it remains unharmed; but let its natural power of resistance be weakened, either along with that of the rest of the body, as in general debility, however occasioned, or through some defect in its own nutrition, and cold air becomes almost as injurious to it as to the peritoneum or pleura.

I have already often had occasion to show you, that the bronchitis of the weak, of the aged, of the emphysematous, is, for the most part, the result of the direct chemical action of the air, on a mucous membrane whose power of resistance is lowered, either by general debility, or by some defect, permanent or transient, in its own nutrition; or, what is more common still, by both. Excluding specific and epidemic influences, the records of bronchitis in the Reports of the Registrar-General, may be read as an illustration, on the broad scale, of this position.

The power of air, under certain conditions, to set up the most intense inflammation of the mucous membrane of the air-tubes was very distinctly shown in a case which fell under my notice some years ago.

It was a case in which it became necessary to perform tracheotomy, to rescue a boy from impending suffocation, produced by rapid swelling in the structures about the larynx, caused by his having accidentally swallowed boiling water. The difficulty of breathing had existed but a short time; there was little or no secondary congestion of the lung; the boy was previously in good health, and the operation was skilfully performed.

Barring the intervention of some new element, therefore, there appeared to be no assignable cause for the particular mischief which followed. But the air which the boy breathed, instead of passing through a long and tortuous channel, and becoming warmed on the way, as in the state of nature, entered now by a short and direct cut into the bronchi. At the same time, the weather was cold; and, as no sufficient precautions were taken to give the air of the apartment a suitable temperature, the result was, the most intense and diffuse bronchitis, which well nigh marred the success of the operation.

That common air may have a very damaging effect on this mucous tract, is, therefore, a fact beyond dispute.

It would be easy to extend much further, if need were, the proof of its operation.

But perhaps, after all, it was scarcely necessary to illustrate at such length a position which you might have found no difficulty in conceding at once.

The fact itself, however otherwise viewed or described, is not only a part of familiar knowledge, but precautions founded on the perception of it are so universal, as to have the force and character of a common instinct.

If, then, the air we breathe have power to set up inflammation on a surface not before diseased, how much more damaging is it likely to be to a surface already inflamed.

The inflamed trachea in croup is sheathed, it is true, from the direct influence of this element by the intervening false membrane.

This is seldom, however, the case throughout the disease. For, besides that in its early stage there is always a time when false membrane is not yet formed, the instances are rare in which even after its formation the larynx is not partially or completely denuded of its adventitious covering, once at least during the course of the complaint. In almost every case, if narrowly watched, it will be found that distinct flakes of false membrane are, at some time or other, coughed up with great temporary relief to the sufferer. So that it is precisely at the moment when the best hopes are excited by the occurrence of this incident, that the prejudicial action of the raw air in keeping alive the inflammation in the now bare and diseased surface steps in to disappoint them.

As the air is more injurious the colder it is, it naturally occurred to me, that the first object in the treatment would be to raise the temperature of the air breathed by the patient to a suitable point. The second was, to saturate the air thus warmed with watery vapour. On many grounds, indeed, it seemed to me not improbable, that—whether by modifying the physical constitution of the false membrane itself—or, perchance, by promoting a more serous secretion beneath it, or in both ways at once—the moisture thus generated might specially aid in the separation and expulsion of the morbid product, and possibly also prevent its being formed anew.

It is for more enlarged experience to say to what degree these important objects are likely to be realised by these simple means.

The results we have as yet obtained are perhaps too few to build upon securely. Nevertheless, as far as they go, they surpass the best expectations that could have been formed of this method of treatment. If they warrant nothing more, they at least encourage to a further trial of it.

The mode of proceeding was, as you remember, simple enough. The sick child was placed in a bed, closed on all sides by a double curtain. Into this bed was introduced a large earthenware pan nearly filled with all but boiling water; and into the water was plunged, from time to time, a heated brick, for the purpose of disengaging steam, care being taken to have the brick completely submerged. By this means, the atmosphere within the curtain was constantly kept at a temperature of from 75° to 80° Fahr., and surcharged with vapour. Where it was practicable, the mother was placed in the bed with the child in order to reconcile it to the strangeness of its situation. As convalescence approached, this was on several occasions found to be a useful precaution.

The only other measure adopted, was to give an emetic from time to time, whenever the struggle for breath seemed more than commonly urgent. Not, however, for the sake of the antiphlogistic effect of the antimony or other agent employed, but to help, by that mechanical succussion which the act of vomiting causes, and which daily experience shows to be so effectual for this end, in the expulsion of the morbid product. This is the great and paramount use of emetics in the treatment of croup, and it is one the more to be valued, *since there is no substitute for it.*

Having entered at such length into the motives which led to the adoption of this plan, it only remains for me to relate, with as much brevity as I can, the results obtained by its employment.

Case 1.—Edwin Poole, a fine robust child, two years and a half old, was brought to the Bristol Royal Infirmary, on the 15th March, 1851. He had been suffering from a severe cold for about a week, but, from the mother's account, it was not until the morning of the 15th, the day of admission, that decidedly croupal symptoms had set in.

On his arrival at the hospital, at about four p.m., his state was already very urgent. The distress of breathing was extreme; the face was livid and bloated, the respiratory murmur scarcely audible. It was plain that the ingress of air into the chest was all but intercepted.

Now and then, in a paroxysm of still greater distress, actual suffocation seemed to be impending. The breathing was loud and stridulous; the cough croupal and characteristic. A layer of white exudation, which visibly coated the velum and fauces, left no doubt as to the nature of the laryngeal obstruction. The pulse 130 in a minute. The only favourable circumstances in the case were, that the heat of the surface still kept up, being in fact rather above than below the natural standard, and that the respiratory muscles still contended vigorously against the impediment which opposed the entrance of air through the windpipe.

As soon as the child was placed in bed, an emetic was administered, two leeches were applied to the top of the sternum, and ten grains of bicarbonate of potash in solution were ordered to be given every half hour.

At five o'clock, as he was growing rapidly worse, two other leeches were applied to the throat; and the fauces, and, as far as it could be reached, the larynx, also, were freely "swabbed" with a saturated solution of nitrate of silver.

These measures were, like the former, followed by no relief, and at half past five, when I saw the child for the first time, he was still growing steadily worse. The breathing had become still more difficult, and the lividity deeper.

As three children, who were admitted in much the same state, and treated by the common methods, had lately died in the house, I determined in the present case to make trial of the plan already described.

The child's bed was accordingly converted into a vapour bath, and he was ordered to have an emetic every four hours. The strength to be supported by good broth, as need might be.

From the moment of beginning to breathe the new atmosphere, the child began to mend. At the end of two hours the change for the better was very striking.

The breathing was much easier and less stridulous, and the lividity of countenance had much diminished. Many hours of tranquil sleep were obtained through the night.

The emetic was administered two or three times, and on each occasion the vomiting was attended by the expulsion of distinct flakes of false membrane.

At one p.m., on the following day, every alarming symptom had disappeared. The breathing had become much more free, and there was not the slightest shade of lividity remaining.

The inspirations were 28, and without labour; the pulse had fallen to 98; the cough had become loose, and had almost entirely lost its croupal character.

In the evening of the same day, he was so well as to be sitting up in bed at play with his toys.

From this time his recovery was rapid and uninterrupted. The vapour was continued for another day, and for two other days the child was kept in close curtains, a precaution which, from the well-known tendency to relapse in croup, it was thought desirable to repeat in all the other cases.

On the 21st the child was discharged cured.

In the next case, the course of the disease was slower, and the distress was at no time so urgent as in that just related.

Case 2.—John Winchester, 22 months old, was admitted to the Bristol Infirmary on the 30th March, 1851, labouring under croup. An attack of measles, which occurred about two months before, had left him weak and cachectic, and he was already on the books as out-patient, for the treatment of cancrum oris affecting the gums of the lower jaw.

A cough, like that of a common cold, which had existed about a fortnight, had, within the last week, gradually put on a croupal character, and, at the same time, the breathing had become more and more difficult.

At the time of admission, the symptoms of croup were fully developed. The cough was characteristic, and the breathing, which was loud and stridulous, was extremely difficult. A distinct false membrane lined the fauces and velum. The complexion was not, however, very livid as yet. The surface hot, and pulse 125. Sibilant and other catarrhal noises were audible over the chest.

The same treatment was adopted as in the former case, and with exactly similar results.

Immediate relief followed the employment of the vapour, and, in the course of six hours, all alarming symptoms had disappeared. Distinct flakes of false membrane were expelled after each emetic, with great relief to the breathing.

On the 1st of April, the breathing was quite free and natural; the cough had become loose, and had entirely lost its croupal character. The symptoms of croup proper had, in fact, disappeared, and only those of catarrh remained. For the treatment of this, and to recruit his general health, he continued in the house until the 17th of April, when he was sent out cured.

Case 3.—Arthur Cross, a fine boy, two years old, was brought to the hospital on the 6th of April, 1851.

In the middle of the night preceding, he was seized suddenly, and without assignable cause, with hoarseness, croupal cough, and extreme difficulty of breathing. On admission, all the symptoms characteristic of croup were fully developed, and the case was considered to be very urgent. The same treatment was employed as in the two former instances. On the morrow, all urgent symptoms had yielded, and the child was convalescent. On the 10th of April he was discharged, well. (May, 1851.)

Since the occurrence of these cases, seven other instances of croup have come to my knowledge, in which the employment of vapour, in the manner already described, formed the principal part of the treatment. Of these seven patients, two only died. In the five others, recovery was rapid, and the employment of vapour was uniformly followed by great and immediate relief.

Of the two fatal cases, one may fairly be put out of the field, as being beyond all hope of remedy when first seen; he died, in fact, within three hours of being brought to the hospital. When admitted, he was already comatose, and a violent attack of convulsions soon followed. On dissection, the false membrane was found to extend down the right bronchus into the minutest air-tubes of the right lung, and nearly the whole of that lung was in the state of collapse, and impervious to air.

The other case did not, at first, appear quite so desperate. The symptoms of croup had, however, existed in great severity three whole days before admission, and, when the child was brought to the hospital, he was already growing drowsy, and the heat of the surface was fast failing. With every act of inspiration, the sternum and sternal cartilages were drawn so deeply in, that it was plain but little air could pass into the chest. Some transient relief seemed to follow the employment of the vapour, but the child died about twelve hours after admission. Two leeches were applied to the top of the sternum, and emetics were not given.

ILLUSTRATIONS OF UNHEALTHY INFLAMMATION.(a)

By M. BROKE GALLWEY,
Surgeon, Royal Regiment of Artillery.

Erysipelatous Gastritis and Enteritis; Evidence of their Occasional, and Probability of their Frequent Occurrence.—Dysentery, an eminently unhealthy form of Inflammation, always asthenic in Nature.—A true Blood-poison Disease.—Absurdity of the Prevailing Fashion of regarding it as a Common Inflammation.—Its Peculiarities dependent upon its Specific Essence, not upon the particular Structure and Locality involved, as, in general, assumed.—Profession not Agreed about the True Principles of Treatment; Bleeding, Leeching, Mercury, each and all Unsatisfactory.—Opium our Sheet Anchor.—Author's Experience of the Disease.

ALLIANCES OF ERYSIPELAS.

Assuming that I have made out a case in favour of the independent existence of erysipelatous affections of the respiratory(b) mucous membrane, from the fauces downwards to the terminal branches of the bronchi; and referring the reader to the evidence which has been afforded, incidentally, while analysing the same, of the occasional co-existence of a similar condition of the pharynx and œsophagus,(c) I should be justified, I think, from *priori* reasoning, and upon every principle of analogy, in claiming for the erysipelatous poison a "right of way," at times, through the length and breadth of the gastro-intestinal mucous membrane, also.

But, although the functions of this latter part of the economy may be arrested for a time by the erysipelatous poison, without that danger to life which attends upon its development in the larynx and bronchial tree, and, therefore, without affording us the same opportunities of verifying, by *post-mortem* inquiries, its existence in this situation as in the respiratory organs, we are, nevertheless, not left entirely to surmise, or to analogy, for the evidence of its occurrence, now and then, in the abdominal mucous membrane.(a) To pass over the constant coincidence of vomiting in the general train of symptoms which characterise erysipelas, and its by no means infrequent associate, diarrhœa,—derangements that might, not unfairly, be assumed to take their rise in a like condition of the mucous membrane, we have the evidence afforded us of an inflamed state of this membrane with effusion into the areolar tissue beneath, in very many of the fatal cases of erysipelas in which it is sought for. In the published histories of such cases, we shall often find this incidentally noticed, though, for the most part, its connexion with the external disease is unsuspected, or passed over. When erysipelas prevails epidemically, then it is that we shall find the gastro-intestinal mucous membrane most generally participating in the influence of the poison, and affording evidence, *post-mortem*, of the presence of the latter, during life. Indeed, so decided is its selection very often, at such times, for this division of the tegumentary membrane, that it is not uncommon to meet with instances in which vomiting and diarrhœa, with tympanitis and, perhaps, some tenderness of abdomen, shall constitute the only disorder in a locality literally steeped in the erysipelatous poison. In a recent number of the *Lancet*, a good illustration was afforded of this occasional eccentric behaviour of erysipelas, in a lecture by Mr. Solly, under the heading, "Hospital Erysipelas of Peculiar Type." This gentleman recounted as many as eleven or twelve cases of the disease, in several of which the external surface of the body showed no participation in the disorder, while, after death, "considerable vascular injection of the mucous membrane of the intestines was found at various parts, as well as extensive diffuse peritonitis, with fibrinous deposits, and a considerable quantity of pus." "The type of the disease," observes the writer, "was peculiar. In all the cases, without exception, there were prominent symptoms of gastro-intestinal irritation."(b)

"An inflammatory affection of the mucous membrane of the stomach," of a peculiar kind, is frequently met with in practice in conjunction with a general inflammatory condition of the whole course of the mucous membrane, from the pharynx downwards. I think it sometimes occurs as an idiopathic disease; but I have generally observed it taking place at an advanced period of other diseases,—as simple fever, or any of the inflammatory affections, as pneumonia. There is a peculiar rawness and tenderness of the whole mouth and throat; often with a dry and glazed appearance of the tongue, a deep redness of the pharynx, interspersed with aphthous crusts; and, in some cases, the whole pharynx presents one continued dense crust of an aphthous character. There is generally tenderness on pressure in the epigastric region, with uneasiness in swallowing, along the whole course of the œsophagus, and great uneasiness in the stomach, excited by the mildest articles of food or drink. In some cases this is immediately communicated to the bowels, and the articles speedily pass off by a rapid diarrhœa. In other cases, vomiting takes place; and in others, both vomiting and diarrhœa." "I have seen the affection assume a very alarming character, with a very rapid pulse, and extreme exhaustion."(c)

(a) The present paper is the continuation of a subject already brought under the notice of the Profession by the writer in the pages both of the *Lancet* and *Medical Gazette*, and unavoidably interrupted until the present time. The greater part of these contributions has been collected, and a few copies may still be had at Mr. Renshaw's, Medical Publisher, Strand.

(c) Loco Citato.

(a) "A woman was brought into St. Thomas's Hospital with some erysipelas of the head and face,—she died a few hours afterwards; and, on examining the body, the mucous membrane of the colon was found extensively and severely inflamed." "A boy, also, lately died in King's Ward shortly after recovering from an attack of erysipelas of the leg and thigh; and, on examining him, extensive ulceration of the ileum was found."—"Dr. Robert Williams on Morbid Poisons," Vol. I.

(b) *Lancet*, March 15, 1851.

(c) "Abercrombie, on Diseases of Stomach, Intestinal Canal," etc. 3rd Edition. Pp. 49, 50. Was this disease erysipelatous in nature, connected with the circulation of deteriorated blood in the system? "I have generally observed it taking place at an advanced period of other diseases;" *i.e.*, under circumstances remarkably conducive to the development of erysipelas.

The literature of medicine abounds with similar illustrations, if searched for, of such evidence, though the connexion of the abdominal appearances with the causes giving rise to erysipelas on the surface, appears scarcely to have been suspected in the histories which disclose it. Louis and Andral are rich in the materials of this unsuspected alliance."(a)

DYSENTERY.

There is something so peculiar, and so eminently *unhealthy* in the origin, progress, and entire deportment of this disease, in each and all of its forms, that I regard it as alike idle and unmeaning to talk of it as a "*common inflammation*" of the mucous membrane of the large intestine, or of its "solitary glands," as has been more recently assumed by Dr. Parkes to be the seat of the morbid process. Whether we regard the disorder under the comparatively benignant aspect which it assumes in temperate climes; or, on the other hand, in its more uncompromising character in intertropical situations, it observes a remarkable consistency in the leading points of its behaviour. Never occurring, as I believe, in a strictly healthy condition of the blood and animal fluids generally, for the reason that the materials for its generation are not then in existence, it is *asthenic* (b) in all its manifestations. I am aware, that this assertion is at variance with the opinions of some of our best and most recent writers upon the disease. Thus, Copland, in his learned and most elaborate article upon this subject, defines it to consist in "inflammatory action of a sthenic or asthenic kind, seated in the mucous surface of the large intestines," etc.,—and the *sthenic* nature of one form of the disease is very commonly described by writers in general as *absolute*, and the opposite to that which they recognise as the adynamic type of the same. But I am of opinion, that *all this is wrong*, and that no form of the affection is essentially one of *power*,—that it is sthenic only in a relative sense, and when studied in connexion with the more demonstratively malignant examples of the disease.

So little, indeed, has it in common with a healthy form of inflammation, that one deservedly high authority regarded the inflammatory phenomena as not essential to the parent malady, "rather as a sequence than as a cause of dysentery, as a contingent effect, and not as a uniform result." (c)

Dysentery, to myself, has always appeared to be in an eminent degree a *specific* form of disease; and though not prepared to assert its identity with erysipelas, I do not hesitate to express the opinion, that its peculiarities appear to me to be best explained by attributing them to the operation of a cause very closely analogous to that setting up the disease in question.(d) Dr. Parkes has broadly alluded to the occasional connexion of erysipelas with the morbid action giving rise to the colonic ulceration. "If the ulceration," says he, "be attended with erysipelatous inflammation of the intermediate mucous membrane," etc.(e); and, in another place, "heat in the course of the colon occurs in some of the erythematous varieties;"(f) and allusion to the same will be found in other parts of his treatise.

In the records which we possess of some of the epidemic visitations of dysentery, the intestinal disorder has ensued immediately upon an epidemic flux of the bronchial mucous membrane, or has alternated with that affection, as in the case of the epidemic in London in 1762, and in that occurring in the following year in Vienna. Wherefrom, we are entitled, I think, to infer the close relationship subsisting between the exciting cause and the morbid action in both cases,—a concordance of intelligible import in this inquiry, if, as I believe, the bronchitis ensuing upon epidemic states of the atmosphere is erysipelatous or erysipelatoid in nature.

The author of the article "Dysentery" in the "Cyclopædia of Practical Medicine" regards this form of inflammation as in no wise differing from that giving rise to "severe diarrhœa," save that "the inflammation of the lining of the digestive canal is more intense and enduring in the former than in the latter disease."(a) Other writers rather look for an explanation of its peculiarities to the particular locality which it selects for its operations,—a solution of the difficulty which I have always thought as unintelligible as it is unsatisfactory. While an indefatigable and colossal author of our own day, would seem to regard the veil which hangs over its obscurity as almost impenetrable, for he declares, that "our knowledge of the disease, even at the present day, is but little in advance of what existed two centuries ago."(b)

Lastly, the pathology of dysentery, by an accurate observer, who has paid very close attention to the subject, and favoured us with the latest treatise upon it, is thought to be satisfactorily reduced to this,—"that it is owing to the glands of the mucous membrane being particularly implicated in the inflammatory action, that ulceration so rapidly and so readily occurs in the common form of dysentery."(c) The evidence and the reasoning upon which Dr. Parkes has supported his views appear to myself so satisfactory, that I think little more can be desired, as far as relates to the visible pathology of the disease.

But, the visible pathology of a disease is one thing, and the occult influence giving rise to it another; and, while I quite accord to Dr. Parkes the merit of having first traced the disorganising process in dysentery to an implication of the so-called "solitary glands" of the colon, I cannot consent with him to leave the matter there, and to conclude, that "inflammation and ulceration of these glands constitute" and clear up all the difficulties and obscurities surrounding the specialty of this remarkable affection; still less can I subscribe to the decree, that dysentery consists in a common inflammation of these follicles. What is it that determines the morbid process to these same structures so exclusively, and what is the intimate nature and essence of this morbid process? This is the really important question; for, until we shall have been able to form some definite notions hereon, I cannot bring myself to feel that we have nothing more to do than to bleed and starve these inflamed and rebellious glands into a cure, and that, in proportion as we blanch them with these agents, the serious and complicated phenomena which make up this disorder will disappear.(d)

It is not a logical deduction, neither is it in accordance, in my opinion, with daily observation, that the train of evils composing the attack of dysentery in hot and unhealthy countries, or during an epidemic outburst of it in our own, can set themselves up under *diametrically opposite* circumstances,—that is, in a healthy state of the atmosphere, and of the humours of the recipient. In other words, that a disease, the peculiar product of bad air and distempered secretions, shall be manufacturable also (to make a word for the occasion) out of materials in every sense the opposite of these, namely, out of good air and healthy humours; for to such paradox do we commit ourselves, when we recognise the sthenic form of dysentery in any other than a relative point of view, and adduce it as an evidence of "common" inflammation of the solitary glands of the large intestine; and this for the reason, that we know that the most finished forms of the disease are the immediate products of all that is poisonous in atmosphere and secretions, springing up in the bold

(a) It will be said, perhaps, by some, allow that erysipelas may develope itself in the gastro-intestinal mucous membrane, to what end such refinement of diagnosis, beyond the fact of swelling the already ample catalogue of medical curiosities? *Cui bono* the knowledge? I answer, a highly practical end. During the existence of an erysipelatous condition of the atmosphere, should a gastro enteritis prevail, and the symptoms run high, it would be our bounden duty to disconnect such affection from the category of common inflammation of the stomach and bowels, turn our back unhesitatingly upon bleeding, leeching, purging, starving, and the like, and address opium, stimulants, and change of air to the complaint.

(b) "An asthenic or exhausted state of the constitution, and of the digestive canal in particular, insisted upon by Marcus, has certainly no mean influence as a predisposing cause, as shown by the greater prevalence of the disease in persons of this description in all climates and in most epidemics, in soldiers after very fatiguing marches, and in convalescents from fevers and other diseases."—*Copland's Dictionary of Practical Medicine*, Vol. I., p. 713.

(c) Johnson on Tropical Diseases, p. 194. Sixth Edition.

(d) In his article on puerperal fever, Dr. Copland associates dysentery with "irritative and spreading inflammation of the vulva, vagina, and cervix uteri," in puerperal women, as equally occasioned by some of the same sources of contamination in close and foul localities; thus recognizing at least the occasional relationship between dysentery and the spreading or erysipelatous inflammation of puerperal disorders.—*Vide Dictionary of Practical Medicine*, Vol. III., p. 505.

(c) Parkes, Loc. Cit., pp. 3, 4.

(d) Dr. Graves says of the dysentery occurring in several parts of Ireland, in 1822, that it was associated with low fever, was characterised by great debility, a rapid and weak pulse, and was very fatal, until wholesome and nutritious food was obtained.—"Transactions of Irish College of Physicians," Vol. IV. Can we conceive the possibility of a form of healthy or common inflammation springing up in the "solitary glands of the colon" out of such materials as these, and requiring to be met by the appropriate remedies for that state of sanguification?

of slave-ships,(a) in over-crowded prisons, hospitals, and so forth, or on the "line of march," where fatigue lends its aid to such combustibles as fetid water, scanty fare, and the like.(b) "We learn from the most certain observations," says Van Swieten, "that whatever is acrid may cause an inflammation, either in the whole body, or in any particular part, by its stimulus. Putrid acrimony, therefore, may bring on an inflammation. How much heat is generated by putrefaction, appears from hay thrown into heaps, which, by putrefaction, will break out into flames."

If an additional argument were needed in proof of the specific or unhealthy nature of dysentery,—and I speak now of the disease in all its forms, and as occurring in temperate climes alike with intertropical,—it is to be found in the disobedience of the disorder under all the usual medicaments in use for common inflammation, as well as in the utter want of harmony among those who have had most opportunities of studying it, as to the most successful treatment of the disease.(c)

During a nearly six years personal intercourse with the disorder, in the Isle of France, where I had opportunities of seeing it in its varied forms, as well in the young and temperate as in those broken down by a long tropical residence and by dissipation, I had reason to be eminently dissatisfied with the routine practice of the day, and especially with that more or less generally in vogue in the adjoining continent of India. I had heard a good deal previously in England, and had read still more about the necessity of meeting the first onset of the disease with venesection, and of combatting the local symptoms with relays of leeches, confiding, absolutely, in the latter, so long as deep seated tenderness could be detected. The first of these I soon had reason to abandon as injurious; and, the second, to set aside as an ally in which no general confidence could be reposed. And, lest it may be urged, that the frequent repetition of leeches is essential to the success of this practice, so long, at least, as tenderness on pressure can be discovered, I wish to be understood as speaking now of their use in that sense more particularly. In my own hands, such practice was abortive as to its control over the deranged action of the part locally; and, I now believe, pernicious in its effects upon the system generally.

But, if the abstraction of blood be not the remedy for dysentery, I can speak with equal confidence, from my own experience, upon a point on which theory might be expected to be no less explicit—I mean the worthlessness of *mercury* for the subdual of the disease. At the time of which I have been speaking, I found my brother medical officers and the civil practitioners of the island for the most part agreed about the pretensions of mercury as a cure for the disease,—pretensions which had had their rise in the extravagant opinions entertained of its merits among the Indian medical men. Thus, the rule that associated dysentery and the mineral in their practice, I found to be "absolute" and unquestioned. My own experience, however, of its control over the disease, at first suggested doubts of its curative influence at all; and, latterly, convinced me that it was not merely inoperative, but prejudicial in the extreme. So far from the tenderness under pressure giving way, the tenesmus and tormina subsiding, and the blood and "corruption" composing the stools giving place to normal dejections under its use, the very opposite of all these was the case, in proportion as the poison was pushed and continued; and this so much as a rule, in my own practice, that I began, at length, to suspect the mineral as at the bottom of the mischief, and, in the end, to be unable to disconnect the two.(a) In order to avoid jumping to hasty conclusions upon the point in question, I administered the mineral in varied forms and doses —by the mouth and by inunction,—in two grain doses and in twenty; and, as a general rule, with the same results in most cases,—to wit, an aggravation of the irritative action already going on in the mucous membrane,—results which, as I have already said, I should have looked for from *priori* reasoning; and, for these considerations:—1st. That the state of the blood in dysentery is the opposite to that in which mercury is found by experience to be beneficial, being one of dyserasy, and in which abnormal elements are superadded. 2ndly. That I believe the natural tendency of mercury is to irritate all mucous membranes even in health, and greatly to aggravate irritation and inflammation when already present in the same.(b) Such, I believe, to be the explanation of the poverty of its influence over mucous inflammations in general—a position, I am well aware, in which I shall not be supported by the general voice of the Profession; but, of the soundness of which I myself entertain no doubt.

What I have had to offer in relation to bleeding, leeching, and mercury, in this disease, is not less appropriate to the use of blisters for the same; in a word, that they are eminently impotent, if not injurious, in their operation.

So much for the worthlessness of the three most potent and valued agents in healthy inflammation, when addressed to the disorder now under consideration; and, if this alone be not a strong ground of suspicion as to the specific character of the action giving rise to it, I know not what stronger to adduce.

But, as I am not writing a *treatise* upon dysentery and its management, it would be foreign to my present object to enter further into what its essence *does* consist in, or to discuss at greater length the question, what treatment *is* adapted to its cure?(c)

Devonport.

(a) "During the slave trade, dysentery was, and even now is among the numerous small vessels engaged in this disgusting traffic, the chief pestilence; one-half of those conveyed in those floating receptacles of misery, on some occasions having died of it during the passage across the Atlantic." —Copland, ut supra, p. 669.

(b) Dr. Copland has briefly alluded to upwards of fifty different epidemics of dysentery occurring in various parts of Europe, from the fourth century down, in each and all of which the disease was, or should have been regarded as, ataxic in character. I say, should have been so regarded, because, although antiphlogistic measures are described as having been instituted in the treatment of some of them, I am by no means satisfied of the applicability of such to the conditions for which they were prescribed. Thus, in speaking of the epidemic "prevalent in Dublin and the vicinity in the autumn of 1825," we are told, that "it was of an asthenic and complicated form, and was very generally treated by bleeding, in robust persons, at an early stage."

(c) "We in vain endeavour," observes Dr. Abercrombie, in reference to acute dysentery, "to find our way amid the various courses that have been proposed for the treatment of the disease."—"Diseases of the Stomach," &c., p. 268. May we not fairly set this down to the universality with which it has been regarded as, and combated with, the measures applicable to healthy inflammation?

(a) An illustrious authority in medicine has well said, "To arrive at any certainty in judging of things useful and hurtful, it is requisite that we attend, with the utmost circumspection to the nature of the disease, else, that will very often be attributed to the medicines given which was owing to the disease only"—(the converse of the rule, of course, being a necessary sequence.)—*Van Swieten's Commentaries on the Aphorisms of Boerhaave*, Introduction to Vol. I., Pp. 26-27.

(b) Bretonneau has some interesting remarks in his work on the "Diphtherite," on the "poisonous action of mercury." "Administrées," says he, "sous toutes les formes, quelquefois pour combattre des prétendus symptomes syphilitiques qui eussent cède aux moindres soins de proprete, les purgatives mercurielles peuvent occasioner des phlegmasies ulcereuses, graves et rebelles, de la peau et du tissu muqueux: souvent, les os eux-mêmes se trouvent aussi affectes." Bretonneau instituted a series of experiments with mercury upon dogs,—with the following results,—that the diarrhœa which is set up in them persisted after the withdrawal of the mineral; and was followed by frequent bloody and mucous stools, marasmus, and death. Gastro-intestinal mucous membrane discovered, *post-mortem*, red throughout. When the dose was pushed as far as it could be carried, the same membrane became pale, instead of red, and attenuated —muscular and peritoneal coats the same. In nearly all the cases which he subjected to this ordeal, there ensued, after a while, "Liquefaction et la discoloration du sang, la prostration des forces, le marasme, et la mort." —P. 205.

What, then, ought we to look for, from the administration of this poison in an already intensely irritated state of the intestinal mucous membrane, and, above all, when introduced into the system in Anglo-Indian doses? In diseases of irritation, we shall almost search in vain for a medicine more hostile to the system, and to the particular structure involved, than this baneful irritant and poison.

Dr. Cheyne, at home, was eminently dissatisfied with mercury, positively as well as negatively, in its application to this disease. Dublin "Hospital Reports," Vol III.; and Mr. Annesley, in India, denounces its employment in the modern Anglo-Indian fashion in the most decided language.—*Vide*, Diseases of India.

(c) I may briefly mention here, in passing, that I believe *opium*, in one form or other, to offer a larger promise of success in every variety of dysentery, than all the other agents in common use for it put together, provided the system be not further depressed by abstractions of blood, and that attention, at the same time, be paid to the all-important consideration of supporting the patient's strength, instead of sinking it by evacuants. I have stumbled upon a remark, in a respectable authority of the last century (Kirkland "on Child-bed Fevers"), very apposite to the present subject, as well as suggestive of the inference, that Dr. Kirkland, as a physician, was in advance of the age in which he wrote. It is this: "I believe there is no kind of fever which will not be moderated by its use" (that of opium); "for if, in inflammatory fevers we join small doses of it with antiphlogistics, and in putrid fevers with antiseptics, we shall frequently prevent the disease having violent effects, and give the proper medicines a better opportunity of accomplishing the intention desired."

"Were the same cases" (of dysentery) "again to be placed under my care, I would not hesitate to give opium in doses of four or five grains, as it was the opium chiefly that seemed to arrest the progress of the inflammation."—Cheyne, Loc. Cit.

See also Dr. Copland's remarks upon the value of opium alone as an antiphlogistic in "some forms of inflammatory disease, in which bleeding would be improper," and in which cases he is persuaded that opium is of itself equal to the cure.—Article "Puerperal Fever," "Dict. Prac. Med."

ON THE USE AND ABUSE OF NITRATE OF SILVER DROPS TO THE EYE.

By T. WHARTON JONES, F.R.S.
Professor of Ophthalmic Medicine and Surgery in University College, and Ophthalmic Surgeon to the Hospital, etc.

Every now and then cases come under the notice of the ophthalmic practitioner, in which the conjunctiva of the lower half of the front of the eyeball and that of the lower eyelid are dyed of a dirty olive-green colour. At the same time that it is thus dyed, the conjunctiva is callous, and often so shrunk that there is scarcely any inferior palpebral sinus left. This state of the conjunctiva is the effect of the long-continued employment of a solution of nitrate of silver dropped into the eye.

Such cases are an evidence, first, of an improper method of applying remedies to the eye very commonly followed; and, secondly, of a misconception of the *rationale* of the operation of the remedies.

Having recently met with some very marked cases of the kind referred to, I am induced to make a few remarks on the mode of applying drops and ointments to the eye, and on their mode of operation.

Mode of Application.—The discoloration of the conjunctiva being confined to the lower half of the front of the eye and inner surface of the lower eyelid, is an evidence that the nitrate of silver solution, which is merely dropped into the lower palpebral sinus, never reaches the upper half of the eyeball, the inner surface of the upper eyelid, and the superior palpebral sinus. Now, this is a very ineffectual mode of applying remedies to the inflamed conjunctiva. To obtain full advantage from any eye-water, drop, or salve, in conjunctivitis, its application should be so managed that it may come into contact with the whole surface of the conjunctiva; and, for this purpose, when it is a solution which is to be dropped in, the eyelids are to be so drawn from contact with the eyeball that the fluid may readily spread itself under them and all over the front of the eyeball, this being promoted by alternately moving the eyelids to and from each other; or, supposing an ointment to be applied, care should be taken to insinuate a small quantity underneath the upper eyelid, whereupon the ointment will readily spread itself, not only underneath the upper, but also underneath the lower, by slightly rubbing the eyelids over the eyeball.

Operation of Remedies to the Eye.—In the first place, it is to be recollected, that it is only in inflammation of the conjunctiva, and in superficial inflammation of the cornea, that stimulating applications, as they are called, are of service. They are unconditionally hurtful in the internal inflammations of the eye. The long-continued use of nitrate of silver drops, whereby the conjunctiva becomes stained, appears to be founded on a notion, that the application has some special unconditionally sanative virtue, so that if it be only used long enough it will effect a cure. In a late number of this Journal, I endeavoured to explain the mode of operation of drops, ointments, etc., in pustular inflammation of the conjunctiva. I would now add, that if an inflammation of the conjunctiva does not quickly yield, more ill than good is likely to result from a persistence in the use of drops, etc., and some modification of the treatment ought to be adopted, suggested by the circumstances of the case, in order to bring the part affected into a state in which it may prove more readily susceptible to the stimulating remedy.

It is not to the purpose to say, that the nitrate of silver solution should never be used as an application. All the benefit that can be derived from its use may be effected without risk of dying the conjunctiva; while other applications, though they may not dye the conjunctiva, will, if as long and as improperly persisted in, prove not less prejudicial in other respects.

Yellow Fever in Demerara.—Accounts from Demerara to 9th May are—Yellow fever increases in malignancy, and is proving more than ever fatal. It is attacking all classes, and all persons who have means or opportunity are said to be flying from the colony. The troops continue healthy, and are still prevented from mixing more than is absolutely necessary with the inhabitants of the town.

THE LONDON PRACTICE OF MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

By JOHN L. MILTON, Esq., M.R.C.S.

CANCER.—SECOND RELAPSE.—THIRD OPERATION.

We have already, in speaking of the removal of a cancerous tumour from the jaw by Mr. Simon, (a) expressed the opinion, that the decision of the difficulties which now surround the question of the removal of cancerous growths would be most rapidly and surely attained by the accumulation of full and detailed hospital reports.

We also, in the same paper, attempted to give the reasons why the surgeon should rather lean to removal than to non-interference; and, as many of our readers may not have seen the paper in question, we trust we shall be excused for giving a brief extract from it. The grounds for operating there put forward are:—

1. Operating undoubtedly saves some patients, and in others is followed by no return of the disease for many years; thus insuring a long interval of ease, and some prolongation of life.

2. When the disease does return, it is not more fatal—for that is impossible—than at its first appearance; and its being more rapidly fatal can scarcely be, in common humanity, considered as an objection, as then the struggle is sharper, and sooner ended.

3. It is better to save even one patient out of twenty, than to lose them all without a struggle; for it may be assumed as nearly a general rule, that at the period when patients will allow the operation to be performed, the disease is always so far advanced, that it would of itself destroy the patient.

4. Most of the operations for cancerous disease are not of a nature to endanger life; and, owing to the discovery of chloroform, not likely to be attended with severe suffering.

Finally, the exact proportion of cases in which cancer returns after removal by the knife, to those in which patients live the rest of their days free from its invasions, is not well known; and, till this is established, no part of the question can be looked on as satisfactorily settled.

Mr. Skey lately operated on a patient, the nature and history of whose case seems to us calculated to throw some light on this subject. From the clinical remarks made in the operating theatre by Mr. Skey, we learn,—

That the patient, a middle-aged man, with a strong disposition to cancerous growths, first presented himself for advice last October twelvemonths, with a suspicious tumour in the upper lip, which Mr. Skey decided on removing. This was done, and the man left the hospital apparently free from disease.

He again presented himself in the summer of 1851, with a scirrhous tumour on the right side of the lower jaw, which Mr. Skey also proposed to remove, considering that it is better to attempt extirpation, when there is any chance of doing so satisfactorily, than to stand by and allow the disease to develope itself. Being about to leave town, he requested Mr. Stanley to undertake the task, which this gentleman at once did. The operation was interrupted by the patient exhibiting some serious effects of the influence of chloroform, under the action of which he had been placed, and it was not till the next day that it could be completed.

He again seemed cured, and left the hospital, with nothing but the cicatrices of the operations in testimony of his disposition to cancer.

But, in January last, he again made his appearance, prepared to suffer anything rather than endure the continuance of the disease which had unfortunately again manifested itself in the form of a small, hard tumour, near the cicatrix of the former one, and apparently attached to the jaw. He had made up his mind to have this removed; but this time Mr. Skey coupled his assent with the proviso, that his colleagues approved of such a measure.

They did so, and accordingly, on Saturday, February 7, Mr. Skey extirpated the tumour. On examining the surface of the jaw there was enough found to excite suspicions that the bone was diseased, and accordingly the greater part of it was at once removed. The man was not placed under the influence of chloroform in consequence of his having suffered so severely and dangerously at the previous operation; but he bore this trial with the most heroic courage.

Mr. Skey remarked, in conclusion, that the prognosis was necessarily most unfavourable, but that, on reviewing all the circum-

(a) *London Medical Gazette*, Dec. 5, 1845.

stances of the case, it appeared that no other plan could be taken up; that the patient was confident and full of hope, though the danger of his condition had been fairly pointed out to him, and that he was willing to face the pain and hazard of the operation, convinced that, if he could not be cured, he would, at least, gain some temporary alleviation of his sufferings.

ST. MARY'S HOSPITAL.

By HARVEY LUDLOW, Esq., M.R.C.S.E.,
Late House Surgeon to St. Bartholomew's.

AMPUTATION AT THE SHOULDER-JOINT.

The period at which amputation for injuries should be performed, has been discussed with zeal and ability by surgeons of the highest reputation; and, although it is impossible to lay down a law universally applicable, and even difficult to a degree to establish rules for general guidance, much has been done to elucidate the subject by the large experience which surgeons of unwearied industry and great professional skill have adduced respecting it. Still, there is no department where more is left to the judgment of the practitioner in each particular instance. Indeed, cases occur on which accumulated experience yields no decisive light, and respecting whose treatment wide observation seems to establish nothing but uncertainty. It is greatly to be regretted, that the statistics of military and civil practice,—statistics, separately of the utmost value,—have been indiscriminately confused together, and the resulting inductions have consequently been impaired in utility, and not free from error. The surgery of the battle-field, excellent as its experience may be when self-applied, affords no accurate illustration of the treatment to be pursued in civil practice; and doubtless, in the exigencies and confusion unavoidable to the conflicts of war, limbs have been sacrificed which, in ordinary circumstances, might have been saved, or at least considered worth an attempt at preservation. In one important particular, however, military and civil surgery agree. As far as I know, the experience of both is decisive respecting the advantages of primary over secondary amputations in injuries which demand removal of a limb. Mr. James, indeed, remarks, in a valuable paper published in the 17th volume of the "Transactions of the Provincial Medical and Surgical Association,"—"Secondary amputations in civil practice, and performed under favourable circumstances, were and are, on the whole, attended with less mortality than primary;" but, if we consider how few are the instances in which secondary amputation is performed under favourable circumstances, this statement is at once altered in aspect, and reduced to narrow dimensions. If it has been decided to amputate a limb in consequence of the severity of the injury, I believe few surgeons in London would recommend the operation to be deferred till the patient is struggling in the stages of hectic and exhausted by profuse suppuration. How disastrous in their termination such conditions become when the shock of an amputation has been superadded to them, is evident from the mortality of secondary operations, in those cases where the attempt to preserve limbs has been followed by excessive suppuration and hectic, and where death results from an operation whose assistance comes too late.

The details of the following case exemplify one of the most prolific sources of fatality in primary amputations,—the collapse produced by a severe injury, and by the operation which that injury necessitates.

COMPOUND COMMINUTED FRACTURE OF THE LEFT ARM. AMPUTATION AT THE SHOULDER-JOINT.—PROSTRATION.—DEATH IN 18 HOURS.

Elizabeth Hill, aged 4, was admitted into St. Mary's Hospital, under Mr. Coulson, at 9 a.m., March 8, having suffered a compound comminuted fracture of the left humerus. She had been run over by an empty truck on the Great Western Railway, about fourteen miles from town, and was brought up to Paddington by train.

The arm was literally smashed. The soft tissues were separated from the bone by a laceration which had rent the skin on the front of the arm, along the inner edge of the biceps muscle, and extended from the acromion to within an inch of the elbow. The bone itself was shattered in fragments from the elbow, into which a fracture extended, to within an inch and a-half of the shoulder-joint. The anterior muscles of the arm were severely torn, but the nerves and artery appeared to have escaped, as there was no hæmorrhage at the time of her admission, and she could move her fingers. When brought to the hospital, she lay in a state of collapse, silent, and heedless of what was passing, the surface of the body being pale and cold, and the pulse feeble. It was, however, stated by those who brought her, that she had lost very little blood, either at the time of the accident, or since its occurrence, but that she was an unhealthy child, and had suffered a short time previously from diarrhœa, and an inflammatory affection of the chest.

Amputation was, of necessity, deferred, her condition not being such as to warrant its immediate performance. In about two hours, however, Mr. Coulson considered that the child had rallied sufficiently to sanction the proceeding, and he accordingly disarticulated the limb at the shoulder joint, the patient being narcotised with chloroform. The operation was modified, in consequence of the injuries inflicted on the soft parts, the principal flap being formed by the deltoid, which was united to such tissues on the inner side of the arm as remained sufficiently uninjured for the purpose. The edges of the wound were brought together with sutures and strapping, and a bandage was subsequently applied. During the operation, the subclavian artery was compressed by Mr. Bullock, against the first rib, and scarcely any blood was lost.

After her removal to bed, the patient continued in a prostrate condition, blanched and powerless. She was ordered tinct. opii miii., ex mist. camph. ʒj., to be taken immediately, and to be supplied, *ad libitum*, with milk, wine, and strong beef tea.

She never rallied; became restless and irritable twelve hours after the operation, and died at 6 a.m., March 9.

Examination of the body thirty-three hours after death,—showed venous congestion on the surface of the brain; the existence of pleuritic adhesions, apparently not old, on the right side of the chest; an empty state of the inferior vena cava, and general anæmia of the heart and great abdominal organs. No other morbid appearance presented itself. For these particulars I am indebted to the kindness of Mr. Bullock, the house-surgeon.

In this case it will be observed, that the operation was deferred, in consequence of the prostration of the patient at the time of her admission. Now the propriety of such postponement has been called in question. It is urged by some surgeons, that it is hardly possible for the system to suffer from a twofold shock at one and the same time, and that, consequently, during prostration, limbs may be removed with safety, inasmuch as the constitution will not suffer from the effects of the operation while occupied by the shock of the injury. With reference to this point, Mr. Travers remarks, ("Constitutional Irritation," p. 144,) "The removal of a mutilated limb, provided the interval of time be so short as to identify the operation with the injury, anticipates, or, at least, infinitely diminishes, constitutional irritation." And, at page 145, "The shock of the injury covers and identifies itself with that of the operation promptly performed."

It does not appear, however, that these considerations have hitherto succeeded in persuading surgeons to operate during the continuance of prostration. Mr. Fergusson ("Practical Surgery," p. 149) says: "It is a maxim almost invariably applicable, never to amputate while the patient is in a state of shock: and, though occasionally it can be deviated from even with success, there can be little doubt as to the wisdom of the delay." In the paper which has been already adverted to, Mr. James states, "that, if amputation is performed while collapse continues, it is a matter of general assent, that it is likely to augment the tendency to death; yet he has known one instance in which amputation was successful, when all attempts to rouse the patient from a state of increasing prostration had failed." Such examples must be rare; experience, however, furnishes but little information on the subject, for few have had the temerity to perform capital operations on patients already trembling between life and death, and whose condition is such, that a few hours may possibly place them beyond the reach of all surgical assistance. Nor is it likely, that a state so desperate would become less so by removal of the shattered member whose mutilation produced it, but rather that the tottering powers of nature would be completely upset, that a heart beating feebly would cease to pulsate, and the faint remains of life be extinguished by the impulse of a fresh injury,—an impulse which, in all probability, the constitution would be powerless to withstand, and unable to counteract. It was scarcely to be expected, that the girl whose case has been related would survive the consequences of the accident. She had recently recovered from an acute inflammation; the injury was extremely formidable; while the feeble vitality of her system was manifested by the phenomena that presented themselves during life, and the anæmia exhibited by the body after death. Fatal, however, as was the termination of the case, it may be doubted whether one more favourable would have followed the earlier performance of the operation, or whether any treatment could have been adopted more likely to have afforded a successful result.

THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

KENT OPHTHALMIC HOSPITAL.

By JOHN WOOLCOTT, Esq.,

Surgeon to the Hospital.

MELANOSIS OF THE LEFT EYE—EXTIRPATION OF THE GLOBE.

Frances Sunnocks, aged 47, married, native of Strood, Kent, of delicate constitution and sallow complexion, was admitted into the Kent Ophthalmic Hospital, Maidstone, under the care of Mr. Woolcott, on the 29th of January, 1852. She states, that originally she enjoyed good health, but, of late years, has suffered much from dyspepsia. Twelve years ago she lost the sight of the left eye, and has had occasional attacks of inflammation in it since that time; but it was not until six months prior to her admission that a small fleshy-looking tumour, about the size of a pea, presented itself on the sclerotica, just below the cornea, on the inner side. The pain in the eye, at that time, she describes as smarting; but pain in the head was what she most complained of. Since then, the pain in the eye and the tumour have gradually increased. Has had six children, all of whom are alive and healthy. Upon examination, the following appearances and symptoms were reported in the Case-book.—"An opaque lens, of dirty yellow parchment colour occupies the pupil, and is pushed with the iris against the cornea, obliterating the anterior chamber, pointing out the existence of some disease at the back of the globe, thrusting these parts forward. A solid fungous mass, of a light purple colour, ulcerated on the surface, and giving rise to a sanious discharge, protrudes through the lids, about the size of a walnut, springing from the sclerotica, just below the inferior margin of the cornea, on the nasal side. On the upper part of the globe, the sclerotica is thinned, and the choroid appears through. There are no glandular tumours of the neck or elsewhere. She complains of lancinating pain occasionally in the eye; excessive pain in the head, interrupting sleep; debility, and a broken state of health; countenance anxious and haggard. Ordered full diet; a glass of port wine daily, and quinine mixture three times a day. A lotion, with equal parts of liq. opii. sed. and water to be applied to the tumour.

Feb. 12.—The tumour having increased very much during the last few days, and the patient's health having been somewhat improved by good diet and gentle exercise in the open air, Mr. Woolcott, this afternoon, performed the operation for extirpation of the eyeball, the patient being under the influence of chloroform. An incision was made at the external commissure, and the palpebræ dissected back; the contents of the orbit were then removed in the usual manner. The bleeding from the ophthalmic artery was but slight, and soon ceased upon the application of cold water with a syringe. Pad and bandage were applied, and the patient was put to bed.

13th.—Slept well, and feels comfortable; pulse quick and full; thirst, and slight feverish symptoms. Liq. ammon. acet. ℥jss., antim. tart. ℈ss., mist. camphoræ ℥vj., M. ℥j., quartis horis sumend.

The patient went on gradually improving, and was discharged on the 1st of March, free from all pain, and much improved in health. She presented herself at the hospital the latter end of last month (May), looking well, and stated that she had not felt so well for many years.

The eye was sent to Mr. Quekett, at the Royal College of Surgeons, who kindly examined it with the microscope, and found it to be a case of melanosis, with the black pigment as yet sparingly developed. The preparation, No. 2255, in the museum at the College, very nearly corresponds with it. The tumour appeared to have originated in the sclerotic.

Medical Times & Gazette.

SATURDAY, JUNE 19.

THE EXTRA-URBEM LICENTIATES OF THE COLLEGE OF PHYSICIANS.

The "Protest" of the Associated Extra-urbem Licentiates of the College of Physicians, which we subjoin, is worthy of consideration, as emanating from a large and most respectable body of men. We cannot doubt that the College will do everything to meet the just demands of the provincial Physicians, and will consider them in the same light as its other Licentiates.

The main objection which Dr. Laycock, on behalf of the Extra-urbem Licentiates, takes to the new Charter, is, that the College demands testimonials of character satisfactory to the Censors. Dr. Laycock objects to this as at once a matter of supererogation and of injustice. He does not think that a provincial Physician, whose standing in the eyes of the public and the Profession may be equal to that of any London physician, should be required to forward testimonials to four Censors, whose acts are irresponsible, and from whose decision there is no appeal. In this we should quite agree with him, did we not think it a matter of primary importance that the College should reserve a legal power of refusing admittance to improper persons. Dr. Laycock admits, that "there are persons practising as physicians whose conduct renders them unfit to be incorporated with the general body." Yet, how are these men to be excluded without some such plan as that adopted by the College? For ourselves, we do not think any Extra-licentiate will suffer much loss of dignity by forwarding a statement of his position and his claims; nor do we think that the Censors would dare to exclude any one from the list, unless they were prepared with evidence in support of their conduct which they felt would be satisfactory to the Profession at large.

We suspect, however, that legally every Licentiate, extra and intra urbem, will, by the spirit of the Charter, be admitted to the membership at the very moment the Charter is granted, and that testimonials will be required only from those practitioners who have not yet joined the College in any form.

With respect to the two money objections, we certainly think some allowances should be made to the Extra-licentiates; but this matter is of comparatively little moment. As regards especially the Stamp-duty, however objectionable this may be, it would be injudicious to make so trifling a matter an objection to what is, as it appears to us, a great boon to all regular physicians in the kingdom.

We do not deem the new Charter the height of legislation. We think its machinery defective, and its organisation far too aristocratic; yet we regard it as a great advance, and as opening a door for the admission of fresh blood into the College, that must soon re-animate its sluggish members, and assimilate it to the progress of the time, and to the wants of the Profession. As an advance, and not as a finality, we accept the Charter; and if the Extra-licentiates are wise, they will do the same.

But we will allow Dr. Laycock to make his protest:—

"PROTEST OF THE ASSOCIATED EXTRA-URBEM LICENTIATES OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AGAINST THE PROPOSED NEW CHARTER.

"To S. A. Paris, M.D., etc. etc., President of the Royal College of Physicians of London.

"Sir,—The Committee of the Associated Extra-urbem Licentiates of the College have had the draft of the proposed new Charter under their consideration, and have desired me to communicate with you respecting it.

"The Committee observe, that it is proposed to incorporate the Extra-urbem Licentiates in a new College, to be called the Royal College of Physicians of England, on the following conditions:—

"1. That they present testimonials of character satisfactory to the Censors. 2. That they pay to the funds of the new College the sum of fifteen pounds fifteen shillings; and 3. That they contribute to the national exchequer by the payment of a stamp-duty.

"As to the *first* condition, they desire me to say, that the Extra-urbem Licentiates already hold letters testimonial as valid in law as the Charter of the College itself; and they are of opinion,

that the rights attached to those letters testimonial ought not to be placed at the arbitrary discretion of the 'Censors.' The Committee also wish me to call your attention to the fact, that they were only granted upon the production of testimonials of character satisfactory to an Examining Board, constituted of yourself, (or your predecessor in the chair,) and three senior Fellows of the College, and are duly signed by the Examiners according to the statute; and that, consequently, any further testimonials are quite unnecessary, unless it be proposed to extend the inquiry to the Fellows and Intra-urbem Licentiates.

"As to the *second* condition, the Committee desire me to say, that they are willing to contribute a proportion of such sums of money as may be found necessary to place the proposed New College in a sound and honourable position; but they would also urge, that it is manifestly unjust to demand the same payment, on admission, from the physician legally qualified, by compliance with the statutes of the realm, as is demanded from the physician not so qualified.

"As to the *third* condition, the Committee cannot comprehend why the incorporation for the public good of a body of professional men, already heavily taxed, should be made the occasion for inflicting further taxation. In addition, also, to the fact, that the majority have already paid a stamp-duty on their diploma, the Committee would state, that the University of Oxford Commission recommends the *abolition of the stamp-duties* on matriculation, and on certificates for degrees; thus affording an example worthy the consideration of the College.

"The Committee would add, that they deeply regret there are persons practising as physicians whose conduct renders them unfit to be incorporated with the general body; but, as such are to be found in every class, they think it both impolitic and unjust to single out one class or more for special inquiry, leaving the others exempt. Further, however unfit any one may be, they think no one should be deprived of his position and privilege by an irresponsible Board, however designated, nor without an impartial inquiry, according to legal forms, and under the guidance of a written code of medical laws, to be appended to or embodied in the Charter.

"The Committee observe, that it is now ten years since the organisation of the physicians of England was first undertaken by the College, and that this is the third draft Charter which it has edited. It is obvious, that this will never pass into a law, and that another attempt will have to be made. On every account the Committee regret these repeated failures, being convinced that they are injurious to all parties, and they cannot but urge most earnestly on the College, the propriety and wisdom of ascertaining, by full and free communication, the feelings and wishes of the physicians of England, both in London and the provinces,—not only as to the terms of incorporation, but also as to the future government of the College; so that they may be all united into one body, jealous of the honour of the Profession, able to defend and maintain its dignity, zealous for the advancement of medical science, and anxious for its application to all those great improvements in social economy which the age so earnestly demands.—
—I have the honour to be, Sir, your most faithful servant,

"THOMAS LAYCOCK,

"Hon. Secretary to the Associated Extra-urbem Licentiates.

"York, June 10, 1852."

THE BURMESE CAMPAIGN.

In May, 1824, the city of Rangoon surrendered at discretion to the first assault of a British army. A noble force scaled, with irresistible impetus, the steep heights of Shoey-Dagon, and drove down the Burmese like sheep. That brilliant feat of arms commenced, and, unhappily, finished, the campaign. For eight long months after it, the victors remained pent up in their narrow fortress, blockaded by the elements, and assaulted by an enemy more fearful than their human foes. With the tremendous rains of the south-west monsoon beating through and through their half-formed camp, the soldiers, smitten down by famine and by fever, died by troops. Between May, 1824, and February, 1825, the unconsecrated burial-places about Rangoon received the bodies of sixty British soldiers who fell in battle, and of more than two thousand who died ingloriously in the pestilential hospitals.

It appears almost incredible that this dreadful lesson should have been thrown away, and that, after nearly thirty years' occupation of Tenasserim, and after full investigation into the Burmese character, the Indian authorities should wantonly and unnecessarily have commenced another Burmese campaign at the very season when war is impossible, and when victory becomes more fatal than defeat. As a military step, the occupation of Rangoon, when advance from it is prohibited, is a mistake. It is a mere sacrifice of men's lives to the fury of the monsoon, and to the malaria of the rainy season. As to any effect being produced on the inert empire of Burmah by this attack on its outpost, it is folly to expect it. The Burman will surrender when the advancing force menaces the walls of Ava, and not till then.

From the middle of May to the end of September, our troops will be quartered in Rangoon in temporary barracks, amid torrents of almost incessant rain. The prodigious quantity of rain which falls during this time is something incredible—one hundred and fifty inches is a moderate monsoon; it is said to reach sometimes to two hundred, and even higher. In the single month of July, more rain has been known to fall than in two years in England. To men unaccustomed to such a climate, badly sheltered, and exposed to the inevitable hardships of garrison duty in time of war, such a season, in spite of all precautions, must be sickly. If the Burmese have not lost their ancient spirit, they will throng beneath the stockades of Rangoon, and keep our distressed troops continually on the alert. The scorbutic dysentery, and the terrible remittent fever, so famous in the former campaign, must re-appear, and, unless immense exertions are made, will be as fatal as in the former war.

If the Indian Government had simply fortified Moulmein against surprise, and had waited till October, they would have had before them six months of cool and beautiful weather, and might have finished the campaign in a few weeks. The *prestige* of an early and rapid blow, so important in the Sikh war, was unnecessary in the Burmese. The two nations are altogether different; and the hesitating policy that was so fatal in 1848 in the Punjaub, was exactly the measure suitable in 1852 amidst the swamps of the Irrawaddy.

There are, however, two circumstances which give great advantage to our arms, and which may possibly in part avert the fatal consequences of the Expedition. One, of course, is the use of steam, by which provisions and munitions may be rapidly conveyed to Rangoon, and sickly troops may be removed or strengthened. The second and equally important difference between this and the former war is, that, south of Rangoon, there is now a friendly population, accustomed to our rule, and disposed to hail the British advent as a step towards the restoration of their own dynasty, and the restitution of their ancient rights. It was, no doubt, in part to confirm the Peguers in their allegiance, and to protect them from forays, that the Indian Government has thus attacked Rangoon. From Moulmein and the adjoining country, provisions of various kinds may be obtained; not, indeed, beef and mutton, but rice of highly nutritious quality, fresh vegetables, and milk. Arracan and Chittagong will also pour in their stores, and, with ordinary exertions, the garrison at Rangoon will not starve on half-putrid flesh, as they did in the last war.

We shall soon see whether the Indian Government, that "splendid anomaly,"—in whose wars the rule seems to be, that victory crowns a series of mistakes and disasters,—has energy enough to meet the present emergency, and to maintain the war it has commenced against the elements. The war with the Burmese will not begin till October; till then, the conflict is with the deluge from heaven and the emana-

tions from the earth. Earnestly do we trust that our forebodings may be erroneous, and that the Indian Government, in plunging headlong into this war, has carefully provided for its inevitable wants.

THE NEW BOARD OF MIDWIFERY AT THE COLLEGE OF SURGEONS.

The Council of the College of Surgeons has announced its intention of appointing a Board of Examiners in Midwifery. This Board, we understand, is to consist of four persons: a Chairman, who is to be one of the Vice-presidents of the College; and three gentlemen practising midwifery. We can only look upon the appointment of such an Examining Board as an indication, that the science of midwifery—for what long remained only an art, has latterly, through the application of physiology, risen into the position of a science—is now taking the place which its importance deserves in the estimation of the Profession. In order to give weight to such a Board, it must be composed of the very best obstetricians — in a scientific as well as practical point of view—which the Metropolis affords; and, to secure the services of such persons, of course, it is only right to hold out a fitting compensation for the use of their valuable time. We question very much, however, whether the Council's idea of liberality is such as to inflame the desire for the appointment in the minds of the leading men in in this department. The Chairman of the Board, as one of the officers of the College, is to be provided for by an annual salary, which we have no doubt is ample enough. The three gentlemen who are to constitute the Board are to be placed on much shorter commons. The fee for examination is to be three guineas. Of this sum, the College takes *two*, and offers to divide the remaining twenty-one shillings among the Board—just seven shillings each. This sum, small as it is, might yet be considered sufficient, if the examination were made compulsory. On an average, three hundred surgical diplomas are granted in the year; if the Midwifery Licentiateship were added to each of these, the Examiners would get three hundred guineas among them, which would certainly not be too much for their time and trouble. But the examination is *not* to be compulsory, and this entirely alters the complexion of the case. The overwhelming majority of those who intend to practise as general practitioners pass through a midwifery examination at the Hall, and of course they will not pay an extra three guinea fee at the College. Supposing, however, one-third of its future licentiates go through the midwifery examination, the splendid sum of one hundred guineas, or thirty-five pounds per annum, will be the remuneration yielded to each member of the Board for weekly hours of worry, and for very much interruption to his practice! Very often, we have no doubt, there will be only a single candidate—and, poor unhappy fellow! we can picture his sufferings—the perfectly savage manner in which he will be interrogated, trembling long upon the very edge of being plucked; for men are men although they be examiners; and we ask deliberately, what must be the feelings of such terrible potentates, after finding themselves dragged, perhaps, miles from their homes at a critical moment for the munificent reward of seven shillings? How could such a Board be hospitable? It might be argued, however, that the honour of the appointment is considered a sufficient reward. Perhaps so. Let the appointment be purely honorary, and all objections cease; but honour cannot be mixed up with seven shillings! If the examination in Midwifery at the College of Surgeons is to be a superior one, the Council must at least treat their Examiners as gentlemen. Why should they not stand on the same footing as the Surgical Board,—the gentlemen composing which receive individually some hundreds a-year as their share of the fees? at all events, we cannot see what justice there is in the College claiming the oyster themselves, and offering little better than a shell to those who are to do the work for them.

REVIEWS.

Manual of Human Physiology for Students; being a Condensation of the Subject, a Conservation of the Matter, and a Record of Facts and Principles up to the Present Day. To each subject are appended, in Notes, Summaries, in Rhyme, of the Composition of the Fluids and Solids, etc. By John Morfold Cottle, Licentiate Royal College of Physicians, M.R.C.S., etc. etc. Small 8vo. Pp. 297. London: Highley and Son.

A good manual is a really useful book. The student of medicine has, in three years, to learn the principles of a host of sciences. To refer him to the original sources of knowledge to attain those principles is absurd. Count the days and working hours included in his three years, and say, could he read a tithe of the important original memoirs which contain facts it is essential he should be acquainted with.

For a manual to be a really useful book, 1st. It must contain the facts discovered in, and the general principles of the science established at, the date of its publication. 2nd. Those facts and those principles must be concisely and clearly stated. 3rd. As far as possible, it should contain references to the original sources from whence the facts, etc., are drawn.

For a man to write a good Manual, then, he must be *au courant* with the literature of his subject; he must be able to estimate the value of the materials at his disposal, and to condense those materials, and then to combine them so as to form a unity, and not a patchwork; and, finally, to express himself easily, concisely, and clearly. Now, we have tried the Manual before us by the above test, and have found it sadly wanting. Here is a specimen of the Author's attempt to be original:—

"The difference in the modes of combination of the atoms of organic and inorganic bodies may be better understood, if for the time being we name the compound atoms of which the bodies themselves are formed, *bricks*. Under such licence of speech, then, we will call the compound atom of the chief of all animal proximate principles, albumine, an *organic brick*, and sesquicarbonate of ammonia, which is an inorganic salt composed of the same proximate elements as albumine, an *inorganic brick*, we will suppose this latter *brick* to be composed of seven elementary angular bodies, which shall represent the seven elemental atoms of the compound atom of sesquicarbonate of ammonia, each having so many flat surfaces, or rhombic plates, that, when one of the seven (carbon) is united to two others (oxygen), their planes so join as to form a perfect rhomb or cube (carbonic acid). When another of the angular bodies (nitrogen) is joined to the remaining three (hydrogen), another quadrangular body or cube (ammonia) is produced, and, by joining the two cubes together, you have an oblong substance of the shape of a *brick* (the sesquicarbonate of ammonia). For obvious mechanical reasons, when this body is knocked in pieces, or into its elements, it will first divide through the middle (into carbonic acid and ammonia), and then into its ultimate elements, the seven angular bodies."

Woodcuts are given to illustrate the various combination of triangles in different organic and inorganic *bricks*. Our author's dissertation on bricks and "concrete" occupies nearly eight pages.

Albumen is, according to Dr. Cottle, an organic *brick*, made up of 114 triangles.

Surely, Dr. Cottle's Manual would, if tried by court-martial, be ordered off to the triangle, it is so intolerably heavy; and he himself is ponderous as a brick; at least, such were our opinions on reading his eight pages on triangles, mortar, and organic and inorganic bricks. But, after we had read the subjoined lines, our opinion was altered, and

we saw that if Dr. Cottle was a brick, he was clearly a "jolly brick."

THE PHYSIOLOGY AND ANALYSIS OF ALBUMINE.

"This fruitful dame, from whom doth issue
The pabulum for every tissue,
Has for the alkalies a balm;
She also can the acids calm.
These and metallic salts involve
With her a tie that wont dissolve,
Save in excess, when she'd be fain
To re-dissolve the same again.
In like excess, you may confide,
That she'll take up a protoxide.
Weak acids, and acetic, proof
Will give, from her they stand aloof.
Heat throws her down; but ah! how strange!
When *weak*, she'll not by boiling change!
Seven from hydrogen 's but few,
Since oxygen gives twenty-two;
Sixteen from nitrogen; and see,
From carbon she has fifty-three.
From phosphorus thirty fractions come;
From sulphur full four times that sum."

It would have been well if the truth of the motto Dr. Cottle has chosen for his title page had been fully impressed on his mind before attempting a manual on Physiology; the motto is Psalm cxxxix. 5.

"Such knowledge is too wonderful and excellent for me; I CANNOT ATTAIN UNTO IT."

By the way, we find Dr. Cottle is a candidate for Bethlem. Judging from the circular by which he announced his advent in the Isle of Wight, we think him well qualified for the place.

The London Dispensatory: a Practical Synopsis of Materia Medica, Pharmacy, and Therapeutics. Illustrated with many useful Tables and Woodcuts of the Pharmaceutical Apparatus, by the late ANTHONY TODD THOMSON, M.D., F.L.S., etc., etc., etc. The Eleventh Edition. Edited by A. B. GARROD, M.D., Professor of Materia Medica and Therapeutics in University College, etc., etc., etc. London: Longmans. Pp. 1230.

We are much pleased with this edition of the justly celebrated work of the late Anthony Todd Thomson; and we hasten to recommend it as a valuable boon to the Profession. It is highly creditable to the editor, Dr. Garrod, who, while preserving as much as possible the matter of the author, has fully and ably indicated the changes which the progress of science has made in the Pharmacopœia. But it were needless to characterise a work now in its eleventh edition. Public opinion has already pronounced it good; and Dr. Garrod has materially enhanced its value. It ought to be in the library of every medical man who can afford to purchase so excellent a manual of materia medica, pharmacy, and therapeutics.

Lectures on Histology. Delivered at the Royal College of Surgeons of England in the Session 1850-51. *Elementary Tissues of Plants and Animals.* By JOHN QUEKETT, Assistant of the Museum of the Royal College of Surgeons. Illustrated by One Hundred and Fifty-Nine Wood-Cuts. 8vo. P. 215. Baillière. London: 1852.

THESE excellent lectures, and the accurate wood-cuts which illustrate them, were last year published in the *Medical Times*. Mr. Quekett has now carefully revised them, and added a considerable amount of new matter. The last two of Mr. Quekett's lectures published in our pages are not included in the present Volume. The type is unexceptionable, and the wood-cuts have come out exceedingly well.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

CHAIR OF THE PRACTICE OF PHYSIC IN GLASGOW.

DR. John Macfarlane, of Glasgow, has been appointed by the Crown the successor of Professor William Thomson in this chair. Dr. Macfarlane, as a practitioner, has long enjoyed a considerable local reputation in the west of Scotland, and as an author has been favourably known by his surgical reports. As a teacher, Dr. Macfarlane has still his reputation to make.

MEDICO-CHIRURGICAL SOCIETY.

ON THE APPLICATION OF THE ACTUAL CAUTERY FOR DESTROYING THE DENTAL NERVE BY MEANS OF ELECTRICITY.

On this subject Dr. Roberts read a communication at the May meeting. The application of the actual cautery by means of electricity in dental surgery was, so far as the author knew, a novelty. For the purpose he used a Grove's battery, the wires of which terminated in small portions of platinum, which were so disposed that the galvanic circle could be closed, and the wires brought to a white heat, by touching a small spring. By removing the finger from the spring, the process was reversed, and the wires became instantaneously cooled. Employed in this way, Dr. Roberts had found the cautery quite manageable, productive of no alarm, scarcely inflicting any pain, and, so far as he had yet observed, satisfactory in its results. The apparatus, which appeared remarkably ingenious, was exhibited.

Mr. Nasmyth had for many years discontinued the use of the actual cautery in caries of the teeth, because, though for a time successful in destroying the sensibility of the affected tooth, he had found its ultimate results to be most unsatisfactory. He had not himself employed electricity as recommended by Dr. Roberts, but his friend Dr. Dewar had, and he was sorry to add without benefit. Dr. Roberts's plan appeared very similar to one suggested by Mr. Harding, in the *Lancet*, for June, 1851.

TEMPORARY ALBUMINURIA AS OCCURRING IN THE COURSE OF CERTAIN FEBRILE OR OTHER ACUTE DISEASES.

Dr J. W. Begbie read a lengthened communication on this important and interesting subject. Temporary albuminaria was defined as the manifestation and continuance of albumen in the urine during a limited period, and unconnected with any serious organic change in the kidney. Dr. Begbie recognised three varieties of temporary albuminuria, each of which found appropriate illustrations in some well known conditions of acute disease. Thus, desquamative albuminaria, the first variety, was found in simple scarlatina, in erysipelas, and in Asiatic cholera. Inflammatory albuminuria, the second type, was illustrated by the condition of the urine, in the dropsy following scarlatina; while, according to Dr. Begbie, a third kind, or critical albuminuria, occurred in pneumonia, and in certain cases of typhus fever. In desquamative albuminuria, the occurrence of albumen was associated with the separation of epithelium, from the mucous surface of the kidney and bladder; and in scarlatina and erysipelas this was likewise connected with a desquamative change in the skin; and, in cholera, with a similar condition of the mucous coat of the intestines. Desquamative albuminuria was also found in some other febrile diseases; but these were, perhaps, the most frequent and familiar. The characters of the urine, under the microscope, (which were described in detail,) presented certain differences in different cases; but there were characters common to all examples of this affection, distinguishing it as a special form of albuminuria. Inflammatory albuminuria was characterised by the presence of renal tube-casts, often granular cells, and frequently of blood-corpuscles, in greater or less abundance, indicating a certain amount of renal congestion and disorganisation. This was the invariable type of the albuminous urine in the dropsy following scarlatina. This form of albuminuria might or might not be temporary; and probably, in some cases, led to permanent renal disease, especially when neglected or unskilfully treated. In most cases, however, it might be looked upon as a curable disorder. Critical albuminuria occurred about the period of resolution in certain fevers and acute inflammations, particularly in the abdominal typhus; and in pneumonia, it was distinguished, not only by the period of its occurrence, and the symptomatic changes with which it was associated, but also by the changes in the urine itself; viz., the precipitation of lithates, etc., as in the ordinary urine at the crisis of acute affections; likewise by the absence of the large quantity of epithelium and other microscopic elements alluded to. These were replaced in the critical albuminuria by a large number of very minute molecules and granules, which Dr. Begbie had been led to regard as the debris of the exudation from the lungs, or other organs, chemically unchanged. The critical albuminaria was therefore to be regarded as the evidence of a change taking place in the previously diseased organ during its restoration to a healthy state.

Dr. Christison said, that his own experience, though consisting of only scattered observations, went far to corroborate some of the results at which Dr. Begbie had arrived. He had not, however, found albuminuria quite so common in scarlatina as had been indicated; and he was inclined to think that, in this respect, as was com-

mon in many others, there might be a difference in different epidemics. In Heriot's Hospital, where he had observed an epidemic along with Dr. Andrew Wood, he thought it possible, that, in some cases at least, the strong derivation to the skin, practised so successfully by Dr. Wood, might have warded off the albuminuria. He strongly advised Dr. Begbie to watch those individuals having temporary albuminaria; he was inclined to believe, that the recurrence of the affection might in many cases be looked for, and that persons so affected too often fell a prey to organic renal disease.

Dr. Andrew Wood detailed, at considerable length, many interesting facts noted by him in the epidemic of scarlatina to which Dr. Christison had alluded. He had found coagulable urine in about one one-half of the cases in which a daily examination had been made. His experience, on some other minor points, differed from Dr. Begbie's. He attached great importance to Dr. Christison's observation as to the influence of treatment in preventing albuminuria; and, in proof of the power it exerted, he might mention, that, in the commencement of the epidemic, there had been a much larger proportion of cases with albuminuria, than towards its close, when he had proved the efficacy of the vapour-bath, and other means mentioned to the Society at a former meeting.

Dr. W. T. Gairdner remarked, that, from the period of his earliest observations in regard to diseases of the kidney, he had been induced to regard albuminuria as a species of catarrhal affection of the renal tubuli, or of the external renal passages. This view, morbid anatomy and clinical study had, in his experience, alike confirmed. Bright's disease he looked upon as the analogue of bronchitis or broncho-pneumonia in the lung. The three varieties of albuminuria Dr. Begbie had described, he (Dr. Gairdner) would prefer regarding as the same affection, differing only in the degrees of intensity, and perhaps from a few other circumstances not perfectly understood. He thought with Dr. Christison, that the occurrence of albuminuria, whether temporary or more permanent, was always to be regarded with suspicion; and he conceived that, if not indicating the actual occurrence of renal disorganization, albuminuria ought generally to be accepted as evidence of a tendency to that affection.

GENERAL CORRESPONDENCE.

SUICIDE BY STRANGULATION.

[To the Editor of the Medical Times and Gazette.]

Sir,—As the following case of "supposed suicidal strangulation" was effected by means exceedingly unfrequent, you will oblige me by giving it a place in the pages of your valuable and widely-circulated Journal. I am, &c.

P. L. Burchell, M.B. Lond., F.R.C.S. Eng.

I was summoned in haste on Sunday morning, March 21, 1852, at ten o'clock, to visit H. D., a man, aged 55 years, who, it was supposed, had destroyed himself. He was formerly a mechanic, but had of late followed no employment, having been supported by the benevolence of a maiden sister. He had lodged for many years in Ravencroft-street, Birdcage-walk, Bethnal-green, where he occupied a first-floor front room in the house of an aged couple.

I found he had been dead for some time, was in bed in a semi-recumbent position, with a silk neckerchief around his neck, tightened by means of the handle of a hearthbroom, which had been twisted half round from right to left, by which firm compression had been exercised upon the trachea, just below the cricoid cartilage; his head had fallen forwards, effectually preventing the head of the broom flying back towards the right side, by which the ligature would have become loosened, by impinging upon the left side of the face and chin; the face was turgid and livid, and a small quantity of blood had issued from the right ear; the tongue was not projected from the month, but some frothy mucus escaped from it; there was some slight ecchymosis in the track of the ligature, but the skin was neither lacerated nor excoriated, showing no unnecessary violence had been used,—the ecchymosis was much more distinct at the spot where the broom handle had pressed upon the trachea, indicating the great probability, that the force had been applied during life; his hands and arms were lying under the bed-clothes as during natural sleep. No *post-mortem* examination was thought necessary by the Coroner, William Baker, Esq., or jury, by whom the case was investigated. I, therefore, was not in a position to speak positively as to the exact cause of death, though certainly the circumstances pointed pretty clearly to strangulation.

From the evidence adduced at the inquest, it appeared that the sister, whose affection had supplied her brother's wants for a long series of years, had, within a few weeks, died in a lunatic asylum, where she had been confined for a short period, by whose death he came into possession of property amounting to about 120*l.* per annum, chiefly household; that an appointment had been made with him by his legal adviser for Monday 22nd, the day after his death, for the purpose of taking out letters of administration to his sister's will; that he had been in the company of that gentleman (who was present and gave his testimony) on the Saturday, the previous day, when H. D. had upwards of 20*l.* in gold and silver in his possession; that he came home in the evening at about his usual time, quite sober, and in his ordinary health and spirits, and asked his landlady, before retiring to rest, to take in a halfpennyworth of milk for him in the morning, and wished her good night as formerly.

At about half-past nine the next morning, as he did not make his appearance, his landlady knocked repeatedly at his door, (which was said to have been locked on the inside,) and called him; but, as no answer was returned, her husband repeated the summons with like effect; the latter then applied his eye to the key-hole, which, being opposite the bed, enabled him to see his lodger in the position before-mentioned; the door was immediately forced open, a policeman called in, and a messenger despatched for my attendance.

There were two or three circumstances, which gave rise to suspicions that the deceased had not come to his death by his own hand; it was questioned by some, if it were possible for him to have committed the act himself. I was appealed to, and gave it as my opinion, that it was quite possible, and I believed it was so in the present instance, and quoted some cases recorded, and, among others, referred to that of General Pichegru, one of Napoleon's generals, who was found strangled in prison by a ligature tightened by a stick, which had been twisted and fixed behind one ear, and alluded to in Dr. Taylor's excellent work on Medical Jurisprudence, but at the same time stated, that it was one of the most unusual modes adopted for self-destruction.

Another fertile source of doubt was the fact, that the money which was sworn to as having been seen on his person the day before, could nowhere be found; nor was it proved to the satisfaction of the jury, that the door of his apartment (though apparently forced, as stated by the landlord) had been fastened on the inside, and that, consequently, free access could not have easily been gained; the window was so secured, so far as it could be ascertained.

The deceased had lived with these people, who bore an irreproachable character, upon friendly terms for many years, and no disagreements had been known to have occurred between them. There had never been any evidence of mental disorder, though insanity prevailed in his family; he had always lived a very quiet, regular life, and was of extremely temperate habits.

In consequence of the doubts which could not be cleared up, the Coroner recommended an open verdict, namely, "that H. D. was found strangled in the manner above represented, but whether by himself or another, there was not sufficient evidence to prove," which was agreed upon by the jury.

Remarks.—Two or three points suggest themselves for consideration in this very interesting case, and it may not be unprofitable to say a few words upon the subject. If the man had been robbed previously to his reaching home, he would hardly have neglected mentioning the circumstance, had he been aware of it; and I should scarcely think an entrance could have been effected from without, and no evidence be left of it, as the fastenings were said to have been secure. The good character borne by the man and his wife who kept the house, forbids the idea that they could have been privy to any unfair dealing; and also the total absence of any indications of unnecessary violence having been employed, which are almost constantly present in cases of homicide, renders suicide much more probable. It is, therefore, in my estimation, most likely that the act was committed by himself,—perhaps, directly on the discovery of his loss, supposing any to have been sustained,—or from some other unknown cause affecting the mind.

The ligature not being so tight as immediately to stop respiration, might account for his being enabled to place his arms in the position in which they were found; and the falling forwards of the head, in consequence of the partially impeded respiration and circulation, producing a soporific condition, would, by this alteration of position, immediately have the effect of increasing the constriction, and produce almost instantaneous insensibility and death.

1, Kingsland-road.

MEDICAL BENEVOLENT COLLEGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am much gratified at the success that has crowned the efforts of the founder of this truly beneficent undertaking, and it cannot be denied but that a goodly sum has been collected, considering it is but through the humble labours of the Medical Profession, to which the clergy have kindly lent their aid.

I much regret when I see correspondents in other journals, such as "a Baptist," and others, raising objections to the proposed laws, although they may not be quite in accordance with the feelings of some of the sects of religion; yet they do not militate materially against the first great principle of this ever-desirable object; namely, the establishing an asylum for those who, alas! have been allowed no rest while carrying out the arduous and ill-paid duties of their profession.

I cannot but think, that while "a Baptist" "has his money in his pocket," he has but little ground of complaint, and that it would, in my opinion, have been more courteous if correspondents forwarded their objections to the Council, who would doubtless be ready to accept and willing to recommend any suggestions which were for the general welfare of the College.

I have as great faith in the desire of the Council to amend the laws as I have in the temperate expression of some of my medical brethren, who as yet have not made known their sentiments; and I am sure there is a wish to conciliate; and, if so, an opportunity will be afforded at the general meeting, when the proposed laws will be submitted for approval; and let us hope we shall be for once united, and get a home for the meritorious and the needy—it is within our command. I know the desire of the many, and the indifference of the few, which I think the following summary will show:—

Received by Hon. Local Secretaries—

Medical donations and subscriptions ..	£180	1	6
Lay do. do. ..	31	4	6
	£211	6	0

If such can be obtained from a district not rich, and from about half the borough of the Tower Hamlets, it may be conceived that the same, or even more, might be accomplished in more distant and wealthier ones. I cannot but express my surprise, on looking over some of the returns, not to find even one medical name recorded, and the paucity in others'; but more so that some of the large towns should be entirely without the pale of the roll, and that the philanthropy of some generous and influential individual has not been aroused to take up this godlike cause.

I should be happy to be the humble instrument to do so, were it in my power, but I can only induce gentlemen to adopt a very simple course,—the substance of the following resolutions and contribution-form,—and not fail to call, if not in Deputation of Committee, in their own right, in company of some friend:—

Moved by George T. Dale, Esq., seconded by Jas. Self, Esq.:—

"1. That the gentlemen present do form a Committee, with power to add to their number, for the purpose of aiding the funds for the establishment, and carrying into effect the objects of the Medical Benevolent College, proposed by John Propert, Esq."

Moved by R. Wallace, Esq., seconded by John Liddle, Esq.:—

"2. That two or more of the members of the Committee call upon every qualified medical practitioner in the Tower Hamlets, and all influential persons who may be willing to assist in the benevolent cause."

Moved by C. Tatham, Esq., seconded by C. J. Tomkins, Esq.:—

"3. That the Honorary Local Secretary be requested to have the foregoing resolutions printed, and that a copy of them, with the address, be sent to every gentleman previous to the call of the Deputation of the Committee.

"MEDICAL BENEVOLENT COLLEGE.

"Contribution-Form.

"Should the Deputation not have the pleasure of seeing you when they call, they will feel obliged if you will kindly fill up this paper in readiness for them. If you have already sent your contribution to the head office, be good enough to notify the same for the guidance of the Honorary Local Secretaries.

Name.	Address.	Donation.	Annual Subscription.

I am, &c. WILLIAM SELF,
Hon. Local Secretary, Tower Hamlets.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have read Mr. Newnham's letter regarding these two charitable institutions with some pain. In common with numbers of my brethren, I venerate the character of Mr. Newnham. I look upon him as a great example of the good one man may accomplish. You must not, therefore, imagine any unkind feeling is mixed with the following comparison of the "College" and the "Fund" which his letter provokes, while it disclaims such desire. That the Profession or the public will support, on a large scale, as "national institutions," two medical charities, is, I take it, a thing not to be hoped for, much less expected. Now, if one is eventually to fall, which, for the good of those for whose benefit both are established, should we desire to remain? Firstly, let us inquire which is most likely to be permanent. The "Fund" certainly realises many of the attributes of genuine charity, but, "like all human institutions, it is by no means perfect." The private character of its benefits, which Mr. Newnham eulogizes so much, is, in my humble opinion, one of its great weaknesses; the world sees not, knows not, the good it does. 'Tis glorious "to do good by stealth;" yet this practical country and age require something more than purity and philosophy in institutions of the character of those under discussion; and, despite all the care of its directors, the "Fund" may foster the beggar by profession, not the really deserving applicant; the secret sloth, or other vicious habit, not the industrious but unfortunate man; and the question arises, whether occasional grants of money might not be more usefully bestowed by a great national institution, uniting in itself all the sympathies of the Profession, and possessed of the essential requisites to secure public confidence, a "local habitation and a name." "In that building which I see, (the benevolent stranger may argue,) live and rest a certain number of my fellow-creatures; they have the means of enjoying plenty and repose after their unsuccessful battle with the world—(the mere ill-temper occasionally seen in every household, adverted to by Mr. Newnham, hardly, I think, needs notice). Within those walls are educated, well educated, a certain number of poor, perhaps orphan youths, who may benefit, perhaps confer honour, on society, instead of degrading and oppressing it through the ills and temptations of poverty. I see one of those edifices which experience tells me are seldom permitted to decay,—the palaces of the Barons, and of darker times, are everywhere crumbling into dust, but the palaces of charity and of enlightened liberty endure and flourish. I see the realization of a grand conception,—the union of these two ideas; into this substantial reservoir of benevolence I will direct my little stream; by the mingling of many waters is the noblest river formed. There is nothing personal about this College: the founder is probably gone to his account; but the good work remains. On the one side, I still see an abode where the wicked cease from troubling, and where the weary are at rest; on the other, I still behold a busy, moving scene,—active, joyous spirits, revelling in life's—like Nature's—happiest season, blooming spring. I fancy the belief pretty generally prevails among those who take an interest in the "Fund," that, should it be deprived of Mr. Newnham's services, its continued existence would be doubtful. His exertions have been great indeed, yet a small capital only is collected. The "British Medical Fund" has ceased to be; it died of its philosophy; and, should the "Benevolent Fund" eventually share the same fate, I venture to predict its chief disease will be, its "purely charitable, unostentatious nature." That the boldness of the College plan commands respect and support, is plain. Mr. Newnham speaks of its "ultimate failure;" can he know that, in a few months, a sum of money and a host of friends, sufficient to insure its success, have been obtained,—10,000*l.* is in hand,—sermons have been preached, and are about to be preached, all over the country in its aid,—local committees will, ere long, be established in almost every town,—together securing an amount of co-operation which renders any speculation as to its failure almost ridiculous? So far from the College "attempting too much," it is its grandeur that has brought success. Men feel justly proud in assisting to build a temple of charity worthy of the Christian religion and of the British name.

I am, &c. CHIRURGUS.

THE BALL-AND-SOCKET FRACTURE SWING.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have just read another letter, in your Journal of the 10th inst., from the pen of Mr. Roberts, on the swing apparatus. He has certainly very much misunderstood the extent of the application of the suspension-board of Sauter, improved by M. Mayor, of Lausanne, and further improved by myself; and I query if he ever witnessed its application. M. Mayor used no splint, but secured the limb on the board through two niches, fastening the leg by means of a bandage at the under part of the board, and suspending it by four ropes, their ends meeting at any convenient distance above the limb, and attached to a single line

from the top of the bed or ceiling of the room. The addition I have made has been a groove for the ropes to pass through under the plane of the board, so as to admit of rotation of the leg on its axis from the hip-joint, by continuing the support to the under part of the leg to the thigh, by placing the limb (when viewed on the side) in an obtuse angle, the whole being secured by a strap to the pelvis. I have also contrived a foot-board, which can be placed according to the length of the limb. The treatment adopted by myself in fractures of the leg, after securing the limb in proper splints, is to place it on the apparatus for suspension, and attach it to any point above the bed, which, if rightly adjusted, the patient can not only revolve the injured limb on its axis and lie on either side, but move up or down in any direction the length of the cord may admit; and also, if necessary, the point of attachment can be removed, and the patient be enabled to sit in on a chair, or recline on a sofa. These advantages I have demonstrated to many of my medical friends, who can testify (and some by their personal experience, unfortunately), to the simplicity, safety, and extensive utility of this mode of suspension. There is another great advantage which this apparatus admits, viz., the facility of applying dressings, if needed, as in compound fracture, gun-shot wounds, etc. In my work, "Facts and Observations in Medicine and Surgery," page 17, is a paper abstracted from the *Journal des Connaissances Medico-Chirurgicales*, written by M. Mayor, in a reply to Dr. H. Larrey, setting forth many arguments in favour of this principle and practice of suspending fractured limbs. On Thursday last, being in London, I went to Guy's Hospital to see an old patient in the accident-ward, who was using the apparatus as suggested by Mr. Roberts. I observed that there are the two principles of the ball and socket joint, and suspension; but I cannot refrain from saying, these advantages are so impeded by the frame as to nullify the utility of suspension. In this reply, I would beg the reader to understand, I can have no other motive but that of desiring to enforce the right application of a principle in the treatment of fractures so well calculated to give ease and comfort to a patient.—I am, &c.,

Crayford, Kent. JOHN GRANTHAM, F.R.C.S.

BETHLEM HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—Although one cannot fail to regret the position in which the eminent visiting-physicians of Bethlem Hospital have been placed, yet, if the agitation which has ruffled the stagnant state of affairs in that well-endowed Institution should succeed in imparting some wholesome activity, people will not be too curious concerning the means whereby it has been brought about.

The system of entrusting the charge of a lunatic hospital or asylum to non-resident officers must go wrong, however able and zealous those officers may be, because the most important influence for good or evil on the patients, is the behaviour and conduct of the attendants under whose charge they are placed; and this behaviour can only be kept up to the sticking-point of vigilant care, good temper, forbearance, and discretion, by the constant supervision of the master's eye. If there is no master, or if he is mainly an absentee, those servants who have not a kind of conscience vouchsafed to few, will, under reiterated temptation, woefully back-slide from their arduous duties, and harshness and neglect towards the patients will be the natural and inevitable result. It may be objected, that sub-officers are always resident, to whom the authority of the absent master may be delegated; but such borrowed authority is like moonshine,—a pale and feeble reflex of the real power.

The Matron of Bethlem has resigned: if the Governors take the opinion of their new superintendent on the appointment of her successor, they will act wisely. The struggle for authority between the physician and this female rival, by whom a *quasi*-medical position is frequently usurped, has been the fruitful source of mischief in many asylums. In most cases, the matron has the best of it; she is not always "an elderly married woman, sedate and grave," and the gallant courtesy of elderly gentlemen may easily glide into partizanship. The doctor also feels that it is unseemly and extremely disagreeable to contend with a lady, however strong-minded and official she may be, so he submits entirely, or agrees to divide the kingdom, and, in the female wards, to practise only in consultation. In several asylums, including some of the largest, the matron has practically the management and moral treatment of all the female patients; she controls the attendants, directs the classification, amusements, and employments of the patients; and, if it were not for the need of a little medical and pharmaceutical aid, would be very happy to do without the doctor altogether.

When the medical superintendent is a married man, and his wife is willing to accept office, there can be no great objection to the use of the word matron, if the lady prefers it to the more intelligible one of mistress; otherwise, the name and office of asylum matron should be for ever abolished, and the duties be distributed between the superintendent, the housekeeper, and the head nurse.

Under the spur of public opinion, the wards of Bethlem may soon, in many respects, emulate those of the best county asylums; the attendants may become cheerful and alert, the windows may be filled with flowering plants, and the walls be covered with prints and birdcages; climbing plants and turf may clothe the prison-like walls and areas of the airing yards; there may be racquet and fives courts, conservatories, dances, concerts, and lectures; and there may be a general activity of useful employment to render amusements more welcome and beneficial; but the roar of London will still be audible,—the air will still be full of blacks and all manner of disagreeable gases, and the only verdant object beyond the walls will be the people going to confession in the opposite building.

Professor Whewell asserts, that the desire for air and exercise is a natural want of mankind, and one of the most powerful "springs of human action." This is true to the fullest extent of that portion of the human race which inhabits our great cities. To a Londoner, jaded with toil and anxiety, a run into the country is not only a delicious enjoyment, but an invigorating remedy to mind and body. If it is all this to the man whose mental poise is correct, and whose nerves alone are a little deranged, what must it be to the poor Cockney lunatic, distracted with cark and care, sensitively anxious about the meaning, and painfully alive to the influence, of all surrounding objects?

The importance of a pleasing and cheerful situation for a lunatic hospital cannot be over estimated. Not only is such a situation thoroughly appreciated and enjoyed by a great number of patients who retain possession of many faculties of enjoyment; but it has often been observed to have a strange and unexpected effect upon those sunk in the apathy of approaching dementia, or the isolation of melancholia.

The author of "Bleak-house" tells us of a philosophic gentleman who was accustomed to visit Staple's-inn to see how countrified the leaves and sparrows looked, and who satisfied his desire to see the country by talking of the "crystal" brook which once ran down Holborn, and the turnstile which once led to green fields there. The imagination of the inmates of Bethlem can scarcely be directed to produce the like contentment, even should they come to the conclusion that the site of the windmill in St. George's Fields, where Justice Shallow and Sir John Falstaff spent a "merrie" night, was in their own immediate vicinity.

In all seriousness, although Bethlem has been twice rebuilt, its present situation and construction is a very bad one; and, if the Governors have the requisite funds, and I could dispose of the existing place in any satisfactory manner, they would do well to remove the whole concern from under the canopy of London smoke. The present building was erected before the great improvements in the treatment of the insane had been effected, and before the means requisite for carrying them out were understood.

The physicians of the sister hospital of Luke's, say, in their centennial Report, published this year:—"We are glad to chronicle the benevolent feelings of those who, a century ago, laid the foundation of so noble a charity; and, be it remembered, that these same feelings have wrought great changes in our times in the condition and treatment of the poor lunatic. The hospital, no doubt, was built according to the opinions, possibly the prejudices, of those times. Tradition seems to have handed down to our ancestors a monastery as the proper model for a lunatic asylum. The first that was built was at Jerusalem, by the monks of the sixth century; and the long galleries and solitary rooms of Bethlem and St. Luke's seem to point to the corridors and cells of the monastery as their original type; but, however this may be, it is undoubtedly unfortunate that our ancestors had not a better model; and it ill becomes those who possess the advantages of modern improvements, to speak lightly of the efforts of those who were actuated by the same benevolent motives which have effected so much good in meliorating the sad condition of the insane."

This just apology will not, however, excuse those upon whom the present administration of the funds has devolved from applying them according to the light of modern science, and in the footsteps of modern improvement.

That man would be more bold than scrupulous or trustworthy, who would undertake, under the same conditions, to send out a greater number of cured cases than those reported from Bethlem by the present distinguished physicians. It can, however, admit of little doubt, that these gentlemen would

themselves not only have sent out a greater proportion of cures, and that these cures would have been of a more satisfactory nature, had they been able to treat their patients in a well-constructed building, situated at some distance from smoky London, and surrounded by gardens and a farm, affording not only space, interest, and amusement, but the most healthy kind of labour. The satisfactory nature of a cure from insanity depends upon its completeness and permanence, and upon the duration of treatment. The number of relapses which occur in the discharges from Bethlem is not known, and depends perhaps more on the treatment which the patient receives from the world after his discharge than from his condition at that period. The average duration of treatment is of great importance, not only to the individual patient, whose time and sufferings are saved by a speedy cure, but to the public, inasmuch as the economy of any system of treatment depends in a great degree upon its brevity. The benefit to be derived from a certain amount of charitable revenue can thus be extended; it being obvious, that, in an hospital containing 200 curable patients, if the average duration of treatment is three months, the same number of cures will be effected as in another hospital containing 400 patients, where the duration of treatment is six months.

If the Governors of Bethlem are not able to remove that Institution altogether into a more suitable locality, there is a middle course which they would find no difficulty in adopting, without delay and without risk of serious loss.

They can sell a portion of their outlying property, buy a farm in some accessible and pleasant situation in Surrey, and build thereon the beginning of a new hospital, in such a manner that it can be occupied as the country house, or convalescent establishment, to the old one. A short residence in such an offset from the parent stock would give to patients approaching convalescence the last filip wanted to complete recovery. It would also be useful to a great number of those still remaining in the town establishment, by affording to them an object of great interest and of anticipated change of scene and enjoyment. Such an arrangement would give room in Bethlem, and render it possible to close some of the most objectionable wards, or to convert them into store-rooms, or workshops, or anything they may be fitted for.

The great hospital would be supplied from the farm with milk, butter, vegetables, and other agricultural produce, and, under good management, the additional outlay would be found to be well invested, even in a pecuniary point of view. Because the labour would be gratuitous; and it has been found, that the labour of insane patients is amply remunerative when employed in gardening and spade husbandry. In handicrafts, such labour is not always remunerative, on account of the greater cost of supervision, and the occasional spoiling of material. In gardening and husbandry the employment is simple and easily directed; it is also much liked by the majority of men, and is, therefore, willingly and cheerfully undertaken. Of course the financial question is very secondary to the sanitary one, and the patients must always be led to employ themselves for their own benefit and improvement, not compelled to do so for the advantage of the Institution.

Apologising for the length of this communication, and trusting that some real and permanent good may arise out of the present turmoil at Bethlem, I am, &c.

A County Superintendent.

CHLOROFORM IN SCOTLAND.

[To the Editor of the Medical Times and Gazette.]

Sir,—In the last number of the *Medical Times and Gazette* Dr. Snow asks me to state the cases of death from chloroform which have occurred in Scotland.

He mentions two cases, both at or near Glasgow, one under the operation of extracting a toe-nail, the other while sounding for stone. I do not know any particulars whatever as to the former case. The common current account of the latter is given in the last number of the *Monthly Medical Journal*, page 554, under some observations on chloroform, to which I beg to refer your correspondent.

In addition to these two cases, I have heard only of one more instance of a fatal result from the employment of chloroform in surgery, and that also near Glasgow. In this instance, chloroform was given by the practitioner for tooth extraction; but, I am sorry to add, none of the parties present were at the time in a condition to give any very satisfactory evidence.

These are the only cases, as far as I know, of death in Scotland from chloroform, among the many thousand cases in which it has now been exhibited in connexion with surgical proceedings; and I believe, that if any others had occurred, I would have been certain to have heard of them.

Before chloroform was introduced, sulphuric ether was reported to have produced the death of one patient in Scotland, who had amputation of the thigh performed, in consequence of a severe railway injury.

One of the surgeons, however, afterwards assured me, that in the dark hovel in which the operation was performed, it was found impossible to secure the vessels sufficiently quickly with the ligatures to prevent the collapsed patient dying from hæmorrhage after the leg was removed; but the ether was a better apology than the hæmorrhage for the man's sudden sinking.

I know of one medical patient who died south of the Tweed, when using, or shortly after using, chloroform, to procure sleep in *delirium tremens*. But, as Dr. Snow is well aware, death often enough occurs suddenly in that disease; and the last thing done is always apt to be blamed for the result. A medical friend of mine had, some time ago, a patient suffering under *delirium tremens*. Opiates, etc., had all failed to produce quietude, or induce sleep. At last, the practitioner, who was watching by his patient, went home to his own house, which was in the immediate neighbourhood, to obtain some chloroform for the purpose of using it as a hypnotic. During the few minutes of his absence in search of the chloroform-bottle, his patient died.

A somewhat similar coincidence happened at the very first introduction of chloroform here. After discovering the anæsthetic effects of chloroform, I was, of course, anxious to get it tried in a surgical operation. The first surgical cases in which it was used, were operated upon in the Royal Infirmary here, on 15th November, 1847. Two days previously, an operation took place in the Infirmary, at which I could not be present, to test the power of chloroform; and, so far, fortunately so; for the man was operated upon for hernia, without any anæsthetic, and suddenly died after the first incision was made through the skin, and with the operation uncompleted. I know of another case in Edinburgh where death instantaneously followed the use of an abscess-lancet without chloroform,—the practitioner, in fact, deeming the case too slight to require any anæsthetic.

While, since the anæsthetic effects of chloroform were known, we have thus had two patients dying in Edinburgh on the operating-table, who did not use chloroform, we have had no death under the same circumstances in the vast number who have now taken chloroform here for surgical operations and other purposes.

Some time ago, I was informed of an instance in which a practitioner urged a patient to use chloroform for the purpose of removing a tooth that had worn her out with pain. She postponed it for a few hours; and, in the meantime, went to bed to procure, if possible, some rest. On going to her room an hour or two subsequently, she was found dead. In this, as in other similar instances, the reputation of chloroform had a narrow escape.

In the different discussions that have taken place, in this country and on the Continent, regarding chloroform as the supposed cause of death in various surgical patients, it appears to me, that it has very generally been forgotten, that patients have ever and anon died during, or immediately after, operations, long before the time of the use of any anæsthetics. But, when such cases occur now, and anæsthetics do happen to be employed in them, the latter are always naturally, though perhaps not always justly blamed. I have already alluded to two such cases that have happened in Edinburgh since the time chloroform was known here; and doubtlessly, if chloroform had been employed in these cases, it would have been taxed with the fatal result. Shortly before the first of these cases, my friend Dr. Robertson had shaved the groin of a patient, and was about to proceed to perform the operation for hernia, when the patient fainted and died, before any incision was made. I have been told of various cases by other surgeons, where the patient died on the operating-table before the days of ether and chloroform, and where the result now would be considered by many as the palpable and indisputable effect of any anæsthetic the patient might chance to use.

In making this remark, I do not, of course, by any means wish to argue, that chloroform may not, and has not proved fatal when used in surgical operations. Nothing could be further from my thoughts or intentions. In the very first paper which I published on the subject, in the *Monthly Medical Journal*, I attempted to warn my professional brethren, that too great or too long a dose "would doubtless produce serious consequences and even death;" and at the same time I ventured to hope, that "its great potency would be one great safeguard against its abuse."

The druggists of Edinburgh have sold, I believe, during the last four or five years, as much chloroform to the medical practitioners and to the public of this city, as would produce anæsthesia in one or two hundred thousand separate instances; and, indeed,

most of the practitioners here use it daily for diagnostic and other purposes, surgical, obstetrical, and medical.

I am sure you will doubt with me, whether an equal amount of full doses of antimony, or of opium, or even of Epsom salts, would not have been followed by a greater number of deaths, occurring perhaps more slowly, but, probably, also more surely. And, on the contrary, this agent, while (like all other medicinal agents), proving injurious now and again in a rare exceptional case, has, I rejoice to think, been already the means of saving, during the last few years, a vast amount of human suffering, and by that means no small amount also of human life.

I am not aware of any death in Scotland or elsewhere from the use of chloroform in midwifery, out of the many thousand cases in which it has now been employed in the old and new world. Nor, indeed, does the obstetric patient run anything like the risk of the surgical patient; for, in midwifery, though the anæsthetic is required to be given for a far longer period, it does not require to be given so deeply as in surgery.

Since November, 1847, I have only attended twelve cases of labour in which chloroform was not used during delivery. In all my other cases I have employed it; and none of those patients, I venture to say, who have used it, would again choose to suffer the unnecessary pains attendant upon labour without it. Most of my obstetric brethren employ it as frequently as I do. After once beginning its use at an obstetric case, I generally leave its exhibition to be continued by the nurse, or by any intelligent friend of the patient who may be in the room. Some of our midwives use it in the cases which they themselves attend. Two weeks ago, one of them told me that she had now employed it herself in her own practice in above fifty cases, with nothing but the happiest results, and without meeting with any circumstances to give her the slightest feeling of uneasiness in its employment.

Chloroform is manufactured to a large extent by three or four chemical establishments in Edinburgh; and as its high price in England has been, I believe, one great cause of its slow introduction into general practice among you, let me state, that with us it is usually sold wholesale to apothecaries at six or seven shillings per pound weight; and it is retailed to medical men at eightpence, and to the general public at one shilling the ounce per weight. It ought to be as cheap in the South.

I am not aware that in Scotland, where chloroform is employed so very extensively and so very successfully by medical men and others, it is ever exhibited by any one except on a handkerchief, towel, or the like; no kind of formal apparatus is used. Doubtlessly, one principal point consists in diluting its vapour sufficiently freely with air, and this can always be readily accomplished when a handkerchief is employed. Some American and English practitioners have proposed to render the vapour of chloroform less strong by diluting it when used with the vapour of sulphuric ether, or of alcohol (as in the so-called chloric ether). But alcohol, etc., often leave headache and excitement, which chloroform does not. And it is surely a thousand-fold better to dilute it with the vapour of "common atmospheric air," than with any other diluting medium.

Perhaps I should add, that twice or thrice chloroform has been used in Scotland by medical men and others to commit suicide; but, of course, Dr. Snow's inquiry does not extend to these cases of its deliberate abuse. He alludes to one of these cases, in which a druggist at Aberdeen destroyed himself by "breathing chloroform for amusement when no one was present;" and he proceeds to speak of a fatal accident "from this proceeding" as a "matter of course." I am not aware of any other similar case in Scotland.

I am, &c. J. Y. Simpson.

Edinburgh.

ON MEDICAL REFORM.

[To the Editor of the Medical Times and Gazette.]

Sir,—Any person debating or writing upon such a theme as medical reform, should, I think, always begin at the beginning, and not with the consideration of the medical corporations and their monopolies—the wrong end. In the first place, then, we wil defer the latter subject, and, instead, just consider what is essentially necessary for the education of all medical men, and then look at the narrow-minded institutions afterwards.

What would be more in accordance with progressive improvement than any system at present in operation? Let us see how many subjects the students ought to study, and the order in which he should proceed: when he is master of them (?) he can easily add others for his own gratification, though not essential:—

First Matriculation.

English, Latin, and Greek composition, at least translate one page from a standard English (medical) author, into good grammatical Latin; a test one hundred times better than translating a Latin author into English.

Natural philosophy.

Elements of mathematics, etc.

Afterwards to be placed on the register as a medical student.

The student's practical studies are three, of which he cannot have too much; viz.—

1st. Anatomical dissections, at least three courses.

2nd. Chemical manipulations ought to have ditto.

3rd. Hospital practice three years.

Clinical Lectures—

1. Clinical medical clerk, six months' pharmacy.
2. Surgical dresser ,,
3. Midwifery assistant ,,

The following courses of lectures, extended over four or five years:—

1. Anatomy and Physiology	3 courses of	6	months
1. Materia Medica and Dietetics	2	,,	6	,,
2. Chemistry and Medical Jurisprudence..	2	,,	6	,,
2. Botany and Comparative Anatomy	2	,,	3	,,
3. Medicine, Surgery, and Midwifery	2	,,	6	,,

With weekly class-examinations in each.

After each session let the student be required to go up and pass an examination, increasing in severity as he advances in his studies, from freshman to senior, previous to the great practical examination granting the degree. If the student be idle, he never will advance in his gradations; if diligent, he will arrive at the long-sought-for goal of his ambition in about five years from the matriculation. It would also have the effect of none being admitted into the Profession but those who were really competent.

In all the present medical institutions, "the blow" (it is more that than anything else) comes all at once, at the end; and when the student is approaching it—his entrance, or may be, final exit—he is quite a tyro; because he has had no preparatory experience as to what it is, and the imagination, ever worse than the reality, he naturally fears. At present the examinations end also, as regards the subject, where they should begin—with the classics.

After the above arrangement, students would not fear any examination, because all the "little goes" would harden them, and they become familiar with the proceedings as they advance; and I have no hesitation in saying, that they would face a ten times tougher examination with unconcern than any at present in existence, not excepting even the University of London.

After a student has obtained the degree, let him follow the bent of his inclination, and practise any branch he may think proper; for he may begin to practise generally, and afterwards cultivate one branch in particular; and when he has been in practice some fifteen or twenty years, he may become a consulting practitioner in the branch in which he is the most celebrated, and sought after accordingly.

The student's whole time is engaged in his own preparation for after life, therefore the apprenticeship-system ought to be abolished; and, if medical men have so much practice, that they cannot get through it themselves, they ought to obtain a qualified assistant, whose thorough knowledge of his Profession renders him fully competent to undertake the necessary duties; and he ought, moreover, to be paid liberally. We have now seen what would be sufficient for all medical men, so, in the next place, we will cursorily look at what we have.

It is true, that we have not undergone such repeated stringent tests as the above scheme proposes; but, at the same time, is there one among us who has not gone through all of the above subjects more or less, and had to deviate according to circumstances afterwards, in order to obtain a title from some one or more of the institutions in existence?

We had to track out our course accordingly; and because the medical institutions of this country are behind the age, is it any fault of ours individually? If a medical practitioner wishes to immigrate to another part of the United Kingdom—say England, is he to undergone an examination again at such a place, for instance, as the Apothecaries' Hall, to be legally qualified; or, if he refuses to do so, is he an ignorant pretender? It requires no refutation.

Science on all sides is leaving our "corporate bodies" sadly in the rear. Each capital of the Empire is now reached in about eight hours or less: and yet we have three different Pharmacopœias established by authority, varying in strength, dangerous in the extreme.

The following are the chief corporate interests to contend with in any reform movement, and they are formidable:—

The Colleges of Physicians of London, Edinburgh, and Dublin 3

The Colleges of Surgeons of London, Edinburgh, and Dublin	3
The Universities—Oxford, Cambridge, London, Dublin, Edinburgh, Glasgow, St. Andrews, and Aberdeen ..	8
The Faculty of Physicians and Surgeons, Glasgow; Apothecaries'-hall, London; and Dublin	3
Principal interests ..	17
Army Medical Board, Navy „ „, East India „, Ordnance. } Supplemental Examinations.	

As there has been a great deal of late written concerning the apothecaries, we will just define the word literally, and then look to its former and present signification.

Apothecary (from *ἀποθήκη*, a repository, from *ἀποτίθημι*, to deposit or lay aside), a store-house for medicines, an apothecary's shop. One who practises pharmacy, one who prepares drugs for medicinal purposes, and keeps them for sale. Formerly, the apothecary merely compounded and dispensed the prescriptions of the physician and surgeon. The term is now, however, also applied in England to those who practise in medicine and *at the same time deal in drugs;* everywhere else they are mere druggists. So much, then, for the apotheeary. Let the term become obsolete, and medical practitioners adhere strictly to their *profession*, and leave the *trade* to *Pharmaceutical Chemists* (*φαρμακευτικὸς*, from *φαρμακεύω*, to use medicines) or *Phamaciens* (*φάρμακον*, a medicine)—the word *Chemist, per se*, inappropriate, as we have only about twenty in the United Kingdom, also the term *Druggist*, as it means an extensive trader—*their sole business being to dispense, not to prescribe medicines*, and preparing medicines according to authority, as in France. A registered apprenticeship requisite, and a penalty for any person commencing without his indentures, or a slight examination, and a penalty likewise, for visiting or prescribing. In country places or districts where there are no *pharmaciens* established, medical practitioners to be allowed to *dispense* until established.

Those colleges that are not requisite, let them afterwards exist as such, minus the power of granting degrees, and act similarly, as in the case of the "Copyright Amendment Act," passed in 1836, when the compulsory delivery of books to the national libraries, supplied by authors and publishers in this obnoxious manner, was reduced from eleven to six, and substitute a money-grant to the others from the Treasury, if it be required. There are, and ought to be, in every large town, Medical Societies, and the present Colleges, as far as bricks and mortar are concerned, would come in very well for the purpose. It is not them we swear to uphold the honour and dignity of, but our noble Profession of itself in general, and our own conduct in particular.

We must be prepared on all sides to make concessions, or we never can meliorate our unsettled and anomalous condition. All interests, then, must yield a little to obtain the desired boon.

Each and every one in the Profession, at the date of any change, must remain *in statu quo*, in one sense, although enrolled under one great head, as no law can be retrospective when the present is a nullity; therefore, we must each enjoy equal rights and privileges, although nominally divided,—become amalgamated into one great brotherhood. Our endeavours must be to agree; individual eminence will always lead the van, whatever the caste. Chartered institutions will not do that for us; so the great need not begrudge what they might consider an encroachment, as each one, after all, will find his own proper level, be he what he may The reality of any change will be for our children, not the present generation.

Then let there be established a Medical Faculty for each kingdom, on the representative principle, for those resident, each sending delegates to form a supreme Senate,—the governing body of the whole Profession in the empire,—to regulate the by-laws and penalties. Every person holding a diploma from any of the present chartered medical institutions to be admitted a member of the Faculty of the kingdom in which he is located.

Now, we must be liberal, or we can never be anything but a set of loggerheads; once join issue on a broad basis, and the Legislature will be too happy to do everything in their power for us. Remember, the inconvenience, if any, will be with ourselves, not the public; even if there should be, it will only be of short duration, and then this mighty discord will be settled for the future. Then, with renewed vigour, and internal peace of mind with ourselves and brethren, we daily meet in our great and good calling,—our sole end and aim being the alleviation of suffering humanity, and goodwill towards all. I am, &c. A SURGEON.

Liverpool.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

JOHN BISHOP, Esq., F.R.S., President, in the Chair.

SMALL-POX AFTER VACCINATION.

Mr. Dendy exhibited a sketch taken from the arm of Sarah Palmer, now in the Small-pox Hospital, who was vaccinated forty-six years ago, when she was a month old, by Dr. Jenner, at Cheltenham, the evidences of which process are four very perfect cicatrices, two on each arm. A short time since, she was with a little boy, who was covered with small-pox. Nine days afterwards, she felt indisposed, and had fever for about five days, when papulæ appeared. The eruption of variola not general over the body; in parts semi-confluent. The disease is mitigated rather than modified, having precisely the same linear character as true variola. She has been, however, free from secondary fever, diarrhœa, hæmorrhage, ptyalism, and delirium, which may probably be attributed, considering the extent and rise of the pustules, to the so far successful vaccination. The eruption was completely different from that which Mr. Dendy terms variella, and which has been (he said) so unwisely called vario*loid*. *A fortiori*, then, this case should be an argument in favour of vaccination, although, *primâ facie*, it might have been deemed against it, judging from the *mere* eruption. Mr. Dendy again referred to the importance of terms and definitions, objecting especially to the adoption of the adjunct *oid*, first applied by Dr. J. Thompson to all pocks, whether capable or not of propagation, and to the *jumbling*, by Rayer, of all spurious or anomalous pocks, as varicella, which produces nothing by insertion.

BONY TUMOUR OF THE UTERUS.

Dr. Crisp exhibited a bony tumour connected with the uterus, which weighed twenty-two ounces; it occupied nearly the entire cavity of the pelvis, was of a globular form, and of so dense a structure, that there was some difficulty in making a section of it. The patient from whom it was taken was 75 years of age, and the chief inconvenience she experienced was a difficulty in retaining her urine.

ULCERATION OF THE APPENDIX VERMIFORMIS, AND OBSTRUCTION OF THE BOWELS.

Dr. Crisp showed a specimen of ulceration of the appendix vermiformis, in which two mortar-like concretions obstructed this cavity, and occasioned the ulceration. The patient had constipated bowels for five days, and died of peritonitis.

A paper from the pen of Dr. Bauer, of Berlin, was read by the Secretary,

ON SPINAL CURVATURE OR SCOLIOSIS.

After alluding to the disadvantages to which this branch of surgical science had been exposed, having been chiefly left in the hands of empirics and quacks, the author proceeded to speak of the various methods of cure proposed, or in fashion at various periods. Some referred scoliosis to disease of the bones of the vertebræ, others of the intervertebral substance; others, again, to a deficient, increased, or perverted action of the muscular system. Thus Strohmeyer attributed it to paralysis of the muscles connected with respiration; Guerin and Major to active retraction of the dorsal muscles, which they believed to exist in all cases requiring section of these muscles. Dieffenbach thought this muscular tension was only occasional, yet sometimes requiring section. But even here observers did not agree; some believing the contraction to be in the convex, others in the concave side. Another opinion was, that the disease was almost wholly constitutional, requiring no local treatment; next, mechanical stretching, treatment locally, was substituted. Delpech soon, however, gave good reasons for abandoning this treatment; but, believing the muscular system to be retarded in its growth, he recommended a gymnastic treatment, afterwards improved upon by Link, the Swede, and known as "kinesitherapie," etc., etc. Dr. Büehring, in Germany, at least, had disproved these contradictory opinions. The objections to Guerin's views were fourfold. 1st. Scholiosis is always produced after certain fixed laws. 2nd. The curvature is not the effect, but the cause, of the muscular contraction. 3rd. Contractions of the large dorsal muscles, *i. e.*, sacro-lumbalis and longissimus dorsi, could never give rise to a sigmoid curvature, but to simple lateral curvature, as in pleurosthotonos. 4th. The negative results of Guerin's mode of treatment disprove his theory. Dr Büehring remarked, first, that new-born children and the fœtus had their spines perfectly straight. Later in life, the spine became curved, and remained normally so, the column inclining to the right side of the median line in the

dorsal, and to the left in the lumbar region. Dr. Büchring accounted for it thus: The head was heavy in the erect position, and necessarily gave the spine a tendency to bend somewhere. 2nd. There was an unequal weight in the viscera on each side of it. The heart was less heavy than the liver; a difference in weight rendered still greater by the active muscular contractions of the heart. 3rd. The distribution of the blood through the left subclavian, was, by reason of its passing off at a right angle from the arch of the aorta, less free than that through the right subclavian; necessarily the muscular structures of the right upper extremity were more developed and heavier than on the left side. Referring to statistics, Dr. Büchring had established, that the proportion where the curvature was not on the right side was 1 per cent.. The returns of the Orthopædic Hospital gave it as 25 per cent. Dr. Bauer, however, insisted upon the accuracy of Dr. Büchring's results, as they were made by a mathematical instrument, which he described, and which left no room for doubt. Dr. Büchring distinguishes four forms of scoliosis: 1st. A curve of tension of three lines, while the plummet line falls on the left side of the rima nature, to form almost a right angle with the horizontal projection. 2nd. Where the plummet line falls to the right side of the rima. The tension of the curves is much increased; the scapulæ have altered their position; left hip projects; but the structural organic changes in the spine have not occurred, and the spine may be artificially straightened for a time. 3rd. These changes are greatly more manifest; the ligaments are firm and the vertebræ rigid. 4th. The changes have reached their maximum; spine is greatly curved; ribs and scapulæ are displaced; the bodies of vertebræ are twisted from right to left. Dr. Bauer next surveyed the different methods of cure adopted by different observers in Germany, and concluded by directing especial attention to Dr. Büchring's mode of treatment. Dr. Büchring acknowledged the accuracy of most of Guerin's and Major's views, excepting in so far as relates to the necessity for myotomy. Looking to the causes of the disease, as before noted, the natural deviation of the column, he regards scoliosis as a state of physical debility, requiring constitutional strengthening measures, and at the same time removes many of the causes of disease by obliging the patients to adopt the recumbent posture. Lateral pressure on the convex surfaces is also conjoined. In some cases, from long persistence of the disease, there is more or less rigidity of the muscles. He does not, for this reason, perform myotomy, but recommends preparatory inunctions with hot oil, but especially with chloroform, which is a very efficient relaxing agent in these cases. The lateral pressure at first is kept up only for a day or two, then removed. After a time, however, it can be borne continuously. Dr. Bauer concluded by extolling this mode of treatment as having been, in all cases susceptible of cure, most successful, and now universally adopted in Germany.

Mr. I. B. Brown read a paper

ON A NEW MODE OF OPERATING FOR OVARIAN DROPSY,

consisting of the excision of a portion of the cyst, returning the remaining portion into the peritonæal cavity, and closing the wound by sutures, thus allowing any fresh fluid secreted by the remaining portion of the cyst to escape into the cavity of the abdomen, there to be taken up by absorption, and discharged by the kidneys. Mr. Brown said this method of treatment was suggested to his mind by reflecting upon the numerous cases on record, in which a spontaneous cure has occurred by an accidental rupture of the cyst, followed by a copious discharge of urine. This mode was not considered applicable to every case, nor was it the purpose of the author to lay down any absolute rules for its use, but simply to relate such facts as had come under his observation.

Case 1.—This case had been alluded to on a former occasion, and Mr. Brown now read the notes of the case as they were taken by Mr. Bullock at St. Mary's Hospital, where the operation was performed. The woman, aged 47, was subject to prolapsus uteri, which Mr. Brown considered as presenting a sufficient objection to treating the case by pressure. The swelling first appeared rather on the left side, about nineteen years ago, but had increased rapidly during the last six months. The following was her condition on admission to St. Mary's Hospital, February 13, 1852:—Abdomen considerably enlarged, with shooting pains extending to the shoulders. Complete procidentia uteri, returned with difficulty. Percussion dull in front, resonant at the sides, less so on the left than the right; fluctuation very distinct, the integuments moving freely over the tumour. Feb. 14th.—Ordinary diet; porter, one pint; blue-pill, three grains; compound aloetic pill, four grains, every night, with saline diuretics. March 6th.—General health good; some fluid drawn from the cyst with a small trocar quite clear, with only a trace of albumen and some chlorides. 10th.—She was placed under the influence of chloroform, and an incision was made through the integuments, down to the linea alba, from an inch and a half below the umbilicus, extending four inches. The linea alba was then divided, afterwards the transversalis fascia, and finally the peritonæum; the cyst then presented to view, and was found to be free from adhesions. It was seized with a pair of forceps, a large trocar was introduced, drawing off about sixteen pints of fluid, leaving some fluid in the cyst, and then a piece of the cyst, which appeared comparatively free from blood-vessels, was excised. The external wound was closed by interrupted sutures, the ligatures including all the abdominal parietes except the peritonæum. She was ordered two grains of opium immediately, and one grain every three hours. A pad of wet lint was placed over the wound, and a broad bandage round the abdomen. Severe peritonitis ensued for the first five or six days, which was subdued completely by large and repeated bleedings from the arm, with calomel and opium. In eight days the abdominal tenderness had subsided, the abdomen became flaccid, and the urine passed exceeded in quantity the fluid swallowed. By the 21st (eleven days after the operation), the remains of the cyst could be felt on the right side of the cicatrix, as a solid substance of an irregular form. On the 3rd of April, no increase of the abdomen could be discovered, and on the 6th she was discharged. Mr. Brown said he expected that the kidneys would continue to secrete more fluid than was drunk for some time, and that the cyst would ultimately become of an indurated, perhaps calcareous character, possessing less vitality, and incapable of secreting fluid. He should feel himself bound to report to the Society any return of the disease, although he did not anticipate a relapse.

Case 2.—In this case, which had been treated nine years ago by tapping, pressure, mercurials, and diuretics, so far successfully that no return of fluid took place for seven years, the abdomen had been gradually enlarging for the last two years, and the patient was anxious for a radical cure, and sanguine as to the result of the operation of excision of a portion of the cyst. She was previously prepared for the operation by a farinaceous and milk diet, avoiding stimulants, and keeping the bowels well open daily, under which treatment the size of the abdomen was materially reduced. The operation was performed on March 29, 1852, in a manner similar to that related in Case 1. Nine pints of clear fluid were withdrawn, and a portion of the cyst excised. But it unfortunately happened that the peritonæal coat of the cyst was very vascular, and hæmorrhage ensued, which was not to be subdued by torsion of the vessels. As there were no adhesions, it was determined to remove the whole cyst. A double ligature having been tightly applied over the pedicle, which was attached to the left ovary, about an inch and a half broad, and containing one large blood-vessel, the pedicle was divided, the cyst removed, sutures applied, and over them a many-tailed bandage. The case did very well, no signs of inflammation having occurred; the ligature came away in four weeks, and on the day following the patient was in her drawing-room, convalescent. This case was related, as illustrating an important difficulty which might occur, rendering the removal of the whole cyst a safer practice than tying several bleeding vessels, and leaving the ligatures within the peritonæum, a source of much danger.

Case 3.—In this case the operation was performed in a similar manner to that detailed in Case 1. A portion of the cyst was excised, but a second large cyst was found, the fluid of which was evacuated, and the wound closed. An attack of inflammation ensued, which was successfully combated by bleeding, and calomel, and opium, and the patient did well. The first cyst became collapsed, and could be easily felt beneath the walls of the abdomen; but the second cyst has frequently filled since; and now, sixteen months after the operation, it fills at a much slower rate, and the patient's health is much improved. Steady and firm pressure has been had recourse to after each tapping, to which Mr. Brown attributes mainly the slower filling of the cyst. This case was related to show another complication which might occur.

Mr. Brown concluded by expressing a hope, that this operation may prove to be another successful method of treating this very troublesome disease.

EPIDEMIOLOGICAL SOCIETY.

At the ordinary meeting of the Society, held at the house of the Royal Medical and Chirurgical Society, 53, Berners-street, on Monday, June 7, 1852, Dr. Babington, the President, in the chair, two very excellent and interesting papers were read, on the important subject of small-pox and vaccination in India.

The first paper

ON THE INTRODUCTION INTO AND PROGRESS OF VACCINATION IN BENGAL.

By Da. C. FINCH, late of H.E.I.C.S., and Presidency Surgeon, Calcutta.

was read by that gentleman, of which we give an abstract. This

paper is an epitome of the history of the introduction and progress of vaccination into Bengal, compiled principally from the reports successively published by the Superintendents-General of Vaccination in Bengal,—Messrs. Shoolbred, Cameron, and Stewart. The periods intervening between the dates of publication comprise so many epochs in the history of this very interesting subject, beginning with the first notice, nearly half a century ago, in 1804, by Dr. Shoolbred, to the year 1829, the date of Mr. Cameron's Report, to that of 1843-44, when Dr. D. Stewart, the present Superintendent-General of Vaccination, presented his first Report to the Government of Bengal. A late and second Report, published by Dr. Stewart, has furnished the author of the paper with materials for adding a supplement, which brings down the account of vaccination in Bengal to the year 1850. The history of vaccination in Bengal furnishes reasons rather for painful commentary than for hearty congratulation, on the introduction to our eastern possessions of the greatest boon which science has yet conferred on mankind, and for deep regret that a boon above all prices should have been virtually rejected by our Indian fellow-subjects, through ignorance and prejudice. Vaccination may be said to have been virtually rejected by the inhabitants of Bengal as a community, notwithstanding the desire and endeavours of the present rulers of India to introduce this inestimable blessing into the countries subject to their rule, placing it within every man's reach, notwithstanding the unwearied zeal and exertions of their medical officers to carry out the purpose of their directors, and notwithstanding the advantages of accepting it being so obvious, and the dangers incident to rejecting it so appalling. Half a century has nearly elapsed since its first introduction, and still we hear of severe and fatal visitations of epidemic small-pox, causing as much havoc in Calcutta as it does in any unprotected population or community. It does not appear that the natives of Bengal could have had any disinclination to adopt inoculation, which seems to have been practised from time immemorial, though the worship of the goddess Situla, who specially presides over small-pox, is general in Bengal; and some of her devotees are so bigoted that they refuse the protection of inoculation until one of their families fall a victim to variola, when they imagine the divinity is propitiated by the sacrifice. Inoculation seems the universal practice throughout Bengal and the provinces subordinate to it, and is one of the chief obstacles to the reception of vaccination. Dr. Finch mentions several obstacles to the successful introduction of vaccination in India; among them, the chief are—1. The dislike of the Hindoos to any innovation. 2. Their apathy or indifference to distant danger. 3. The practice of inoculation for small-pox. 4. Climate; which for one-half of the year is unfavourable to vaccination. 5. Want of confidence in its protective powers,—this last objection being of latest origin and of most obstinate tendency. A retrospective view of the introduction of vaccination does not offer any very immediate prospect of its general adoption by the natives of Bengal.

The second paper read was written by H. J. Stewart, Esq., Assistant-surgeon Bombay residence.

The reading of both papers occupied the time allowed for holding the meeting.

MEDICAL NEWS.

University of Oxford.—The Fielding Herbarium, presented by Mr. Fielding, of Lancaster, together with a choice collection of works on botany, has been accepted by the University authorities, who have set apart a sum of 2000*l.*, the interest of which is to be applied to the maintaining and adding to the collection. The curators are to be the Professor of Botany and the Regius Professor of Medicine; and a third, to be appointed by the other two, from among the members of the University. A further sum of 1250*l.* is set apart for providing a suitable building in the Botanic Garden for the reception of the collection. Dr. Daubeny, the Professor of Botany, speaks in the highest terms of the value of this collection, as does also, it appears, Sir W. Hooker.

University of Glasgow.—We understand, that Mr. Secretary Walpole has appointed Dr. John Macfarlane to the vacant Professorship of Medicine in the University of Glasgow.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 11th inst.:—

Austen, Josiah, Plymouth.
Church, George, Listowell, Kerry.
Clarke, John Andrew, Army.
Coombs, Savill James, South Lambeth.
Kelly, James Douglas, Liverpool.
Lankester, Henry, Poole, Dorset.
Martin, James, Quebec, Canada.
Mason, George, Deal.
Morris, George Selwyn, Wye, Ashford, Kent.
Murphy, John Barry, Cork.
Smith, John, Daventry.
Streatfield, John Tremlyn, Wanstead, Essex.
Wild, Thomas, Ramsbottom, Lancashire.

The Fellowship.—The Council of the Royal College of Surgeons have just announced that the next examination for this distinction will be held in the first week of the ensuing month, for examinations in classics, mathematics, and French. The professional examinations for the senior candidates will take place in August next.

New Councillors.—The Fellows of the Royal College of Surgeons have received summons to attend a meeting of their order in the hall of the College on Thursday, the 8th day of July next, at one o'clock in the afternoon, for the election of four Fellows into the Council of the College, in the room of three members going out in rotation, and of John Dalrymple, Esq., deceased. From the bye-laws of the College, sent to each Fellow of the Institution, it appears, that a notice of the intention of any gentleman to present himself as a candidate for a seat in the Council must be sent in within ten days from the publication of the advertisement in the *London Gazette*. This bye-law does not appear to have been generally understood, as only a very few (we understand four or five) have complied with it. The members of the Council now resigning their seats are Messrs. Bransby Cooper, Coulson, and Stafford; the two first-named gentlemen there can be no doubt will be re-elected. Mr. Stafford having resigned, there remain two vacancies to fill up; this will be done from the gentlemen who have offered themselves, viz., Messrs. Gulliver, Tatum, Shaw, and Partridge,—all good men, and deserving of the object of their ambition, and from whom the "Fellows" will have a difficult task to select.

Collegiate Appointments.—The Profession will no doubt hail with great satisfaction an act of distinguished consideration on the part of the Council of the Royal College of Surgeons towards one of their officers, to whom we, in common with the Profession generally, are so much indebted,—we allude to Mr. John Thomas Quekett, the Resident Conservator, who, at a meeting of the Council yesterday, was unanimously elected their Professor of Histology. At the same meeting, Mr. John Henry Sylvester, of Cheltenham, and formerly of King's College, was appointed student in Human and Comparative Anatomy, after a severe competition, in the vacancy occasioned by the retirement of Mr. D. H. Monckton.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 10, 1852:—

Cockburn, James Balfour, Gurnsey.
Damant, Thomas William, Fakenham, Norfolk.
Foquett, Henry Richard, Newcastle Emlyn, Cardigan.
Hawkins, Benjamin Lawrence, as an Assistant.
Hewer, John Henry, Chobham, Surrey.
Hooper, Joseph, Milton-terrace, Wandsworth-road.
Lock, Ezekiel John, Barton, Norfolk.
Jones, William Price, Bala, North Wales.
Rolph, James, London.

Military Appointments.—6th Dragoon Guards: Surgeon George Taylor, from the 81st Foot, to be Surgeon, vice John Heriot, M.D., who retires upon half-pay. 29th Foot: Acting Assistant-Surgeon John Smith Chartres, to be Assistant-Surgeon, vice Stewart, promoted in the 94th Foot. 40th Foot: Acting Assistant-Surgeon William Tidmas, to be Assistant-Surgeon. 81st Foot: Staff-Surgeon of the second class Adam Thomas Jackson, M.D., to be Surgeon vice Taylor, appointed to the 6th Dragoon Guards. 94th Foot: Assistant-Surgeon Ludovick Charles Stewart, from the 29th Foot, to be Surgeon, vice Thompson, deceased. Hospital-staff: Assistant Staff-Surgeon William Rutherford, to be Staff-Surgeon of the second class, vice Jackson, appointed to the 81st Foot; Acting Assistant Surgeon Edward Walker Skues, M.D., to be Assistant-Surgeon of the Forces, vice Booth, promoted in the 73rd Foot. Acting Assistant Surgeon Arthur Edmund Jacob, to be Assistant-Surgeon to the Forces, vice Rutherford, promoted on the Staff.

Naval Appointments.—Surgeons Edward H. Cree, M.D.

(1843), to the Spartan; William R. Dalton (1846), to the Vestal, 26, at Sheerness. Surgeon-Superintendent William H. B. Jones, M.D. (1837), to the Boscawen, 70, at Chatham, vice Gunn; John Dunlop, M.D. (1833), to the Sampson, vice Donnelly; Samuel Donnelly (1842), from the Sampson steam frigate, to the Lady Montague, hired ship. Assistant-Surgeons F. C. Sibbald, M.D. (1846), to the Spartan; Alfred Jackson (1847), to the Vestal; Robert Irvine (1848), to the Cumberland, 70, flagship, on the North American and West Indian station; G. F. A. Drew (1851), confirmed to the Inflexible; James Sproule (1851), confirmed to the Scorpion.

NAVAL APPOINTMENTS AND PROMOTIONS.—Assistant-Surgeon Robert Beith, M.D. (1841), serving at Greenwich Hospital, to be Surgeon.

MR. HENRY S. GAYE was last week appointed House-Surgeon to the Taunton Hospital.

LIEBIG.—Letters from Munich, of the 8th, state, that Professor Liebig has at length yielded to the inducements held out to him by the Bavarian Government to leave Giessen, and settle at the University of Munich. He is to commence his labours there with the winter session.

SCARLET FEVER.—A sad announcement appeared in the *Times* on Monday last, to the effect, that a magistrate, residing on Addison-terrace, Notting-hill, aged 35, his wife, aged 28, and their child, aged 3 years, with the wife's youngest sister, had all died in one week, of malignant scarlet fever.

THE following votes in behalf of science and medical charities have passed the House of Commons. 2006*l.* for the salaries and allowances to certain Professors at the Universities of Oxford and Cambridge; 3957*l.* for the University of London; 7560*l.* for the grants to the Scottish Universities; 300*l.* for the Royal Irish Academy; 1710*l.* for the Queen's University in Ireland; 21,350*l.* for new buildings for the British Museum, and 52,243*l.* for the salaries and expenses of that Museum, besides 2266*l.* for antiquities; 14,920*l.* for the Museum of Practical Geology; 4018*l.* for scientific works and experiments; and 2000*l.* for the expenses of the National Vaccine Establishment.

QUACKERY.—Several correspondents have directed our attention to the advertisements of a member of the Royal College of Surgeons practising in the county of Buckingham, as illustrative of the grossest quackery. One in particular in the *Cambridge Independent Press*, addressed to the students of the University, is very bad. But we have great pleasure in informing our friends, that the Council of the Royal College of Surgeons have the case before them, and are taking measures to purge the College of such characters, who have sworn to uphold the honour, dignity, and welfare of the Profession.

DEATHS *in the Metropolis for the week ending Saturday, June* 12, 1852.

TO CORRESPONDENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—My attention has been called to a paragraph in the "Medical Times and Gazette" of the 29th ultimo, in which it was stated, that I "had received orders from Dr. Andrew Smith to hold myself in readiness to proceed to Chatham, preparatory to my entering the Army as Assistant-Surgeon." I beg to say, that your informant has been misled, and that I have merely received intimation from the Head of the Army Medical Department that my name has been placed on the list of candidates for a commission.

I am, &c.

16, Trinity College, Dublin. SAMUEL GIBSON, M.B.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your report of the presentation of the Rainey Testimonial at this Hospital, I observe one or two errors of omission, which it is due to Mr. Rainey not to pass over unnoticed.

Though essentially a students' testimonial, nearly the whole of our medical and surgical staff were subscribers, having sent in their subscriptions to the Committee unsolicited, and thus paid a high compliment to our talented Demonstrator. Not only was the microscope complete, but it was fitted with every convenience, and all the most approved apparatus for correct microscopic observation, their value being very little short of one hundred pounds.

It is by our School being superintended by such men as Mr. Rainey which elevates it so high in the estimation of the Profession.

I am, &c.

St. Thomas's Hospital. A MEMBER OF COMMITTEE.

Scotus has not authenticated his letter; it is, moreover, an advertisement.

We shall be obliged to *Amicus* to obtain the reports to which he alludes, and shall be glad to see him any Tuesday, Wednesday, or Thursday, between 12 and 2, on the subject.

J. J.—We will endeavour to answer the question.

Erratum.—By an inadvertency in our last, the papers of Mr. Barlow were announced as concluded. Such is not the case. They will be continued at once.

[To the Editor of the Medical Times and Gazette.]

SIR,—I most cordially agree with the sentiments expressed in your last by a Graduate of a British University, and sincerely hope the authorities of the Hall will see the justice and expediency of admitting those gentlemen in actual practice who are already licensed by legally constituted medical boards of the United Kingdom. All measures of proposed medical legislation have recognised their claims as general practitioners. The Hall would lose no reputation by enrolling among its licentiates, and extending its protection to, a well qualified class of men, who would, I feel sure, gladly avail themselves of such a privilege. I am, &c.

AN OLD SUBSCRIBER AND ANOTHER BRITISH GRADUATE.

Caritas, Harrogate.—We do not think it becoming the dignity of a surgeon to advertise himself week after week in the columns of a newspaper, side by side with tailors and house agents; nor do we think it much mends his case to say, that he only notifies to the world, that he has removed from one house to another.

Mr. J. J., Islington.—An editor, attacked *as* editor, has no ill-feeling towards his adversary. We think an apology was due to us, and accept it in the spirit in which it is made. Our columns for this week, at least, are full.

H. F. H, Hertfordshire, is thanked for the MS. and newspaper.

Chirurgicus.—We saw the nonsense in the Journal mentioned. Really such trash is beneath notice. London surgeons can afford to smile at it. *They*, at least, can attribute it to its true cause; *they*, at least, could place a finger on the sore spot.

A Student and Subscriber.—We presume so; but a letter to Mr. Belfour will elicit the fact.

A. E. J.—Apply to the Emigration Board.

THE Correspondence relating to the Manchester Medico-Ethical Association reached us too late for our present Number.

COMMUNICATIONS have been received from—

SCOTUS; M.; Mr. RUSSELL REYNOLDS, of Leeds; Dr. HIGGINS, of Birkenhead; Mr. WHITBY, of Ottery, St. Mary; Dr. MARLOW, of H.M. 28th Regiment, Sunderland; Dr. BIRD, of Hyde-park-square; Mr. N. WARD, of the London Hospital, and Broad-street-buildings; Dr. TUANDULL, of Liverpool; Mr. GRANTHAM, of Crayford, Kent; Mr. LUDLOW, of Paternoster-row; Mr. CLOSE, of Manchester; Dr. WALSHE, of University College, and Queen Anne-street; Dr. SIMPSON, of Edinburgh; Dr. BURROWS, of St. Bartholomew's Hospital, and Cavendish-square: Dr. KIRKES, of St. Bartholomew's Hospital; AMICUS; J. J.; CHIRURGUS; Mr. MASON, of Holloway; A. E. J.; Mr. HOWE, of Newtown; A COUNTRY SURGEON; A STUDENT AND SUBSCRIBER; KAPPA; Dr. GREGORY, of the Small-pox Hospital, and Camden-square; ZETA; CARITAS; H. F. H.

ALLSOPP'S PALE OR BITTER ALE.

In consequence of the reported adulteration of Bitter Beer, Messrs. Samuel ALLSOPP and SONS have received numerous incidental TESTIMONIALS to the excellence, purity, and salutary effects of their ALES. They consider it due to the Medical Profession who have so long recommended ALLSOPP'S PALE ALE in all cases where dietetic regimen is required, to give publicity to these Testimonials, as a means of disabusing the public mind of any possible prejudice on the subject.

By the following extracts among a number from the most eminent Medical Men, the Profession throughout the country will have the satisfaction of finding their just appreciation of the remedial advantages of ALLSOPP'S PALE ALE amply confirmed by the concurring testimony of the most able Physicians and Surgeons, as well as the most illustrious Chemists of the time :—

FROM BARON **LIEBIG.**

"The specimens of your PALE ALE sent to me have afforded me another opportunity of confirming its valuable qualities. I am myself an admirer of this beverage, and my own experience enables me to recommend it, in accordance with the opinion of the most eminent English physicians, as a very agreeable and efficient tonic, and as a general beverage both for the invalid and the robust.——" Giessen, May 6."

FROM PROFESSOR **GRAHAM,** F.R.S., UNIVERSITY COLLEGE, LONDON; AND PROFESSOR **HOFMANN,** Ph.D., F.R.S., COLLEGE OF CHEMISTRY, LONDON.

"The sifting nature of the chemical examination which the Beers of Messrs. ALLSOPP's manufacture for many months past have been subjected to, fully establishes their incontestable purity. The process of brewing PALE ALE is one in which nothing but Water and the best Malt and Hops of the first quality are used: it is an operation of the greatest delicacy and care, which would be entirely ruined by any tampering with the materials employed. ——" London, April 26."

FROM THE **ANALYTICAL SANITARY COMMISSIONER** OF THE "LANCET," MAY 15, 1852.

"From the pure and wholesome nature of the ingredients employed, the moderate proportion of alcohol present, and the very considerable quantity of aromatic anodyne bitter derived from hops contained in these Beers, they tend to preserve the tone and vigour of the stomach, and conduce to the restoration of the health of that organ when in a state of weakness or debility. They resemble, indeed, from their lightness, a *wine of malt*, rather than an ordinary fermented infusion; and it is very satisfactory to find, that a beverage of such general consumption is entirely free from every kind of impurity.

FROM SIR **CHARLES M. CLARKE,** BART., PHYSICIAN TO HER LATE MAJESTY THE QUEEN DOWAGER.

"I have frequently recommended BITTER ALE medicinally, and when my home-brewed Ale has been exhausted, I have been supplied with Ale 'from your brewery.'——" Wigginton Lodge, May 2."

FROM **THOMAS WATSON,** M.D.

"In the genuineness and salubrity of PALE ALE and BITTER BEER, as manufactured at Burton, my confidence remains unshaken." ——" Henrietta-street, Cavendish-square, May 5."

FROM **GEORGE BUDD,** M.D., SENIOR PHYSICIAN OF KING'S COLLEGE HOSPITAL.

"I did not want any testimony to satisfy me of the perfect purity of the PALE ALE manufactured by you. A close observation of its effects upon myself and upon many others to whom I have prescribed it long ago, convinced me, as much as the most searching chemical analysis could do, that it contains nothing more than malt and hops, and that it is a first-rate beverage.——" Dover-street, May 1."

FROM **MARSHALL HALL,** M.D., F.R.S.

"My confidence in the purity of your PALE ALE remains unshaken, and my opinion of its great value in a dietetic and remedial point of view, is entirely confirmed by long time and experience.——" Grosvenor-street, April 30."

FROM **BENJAMIN TRAVERS,** ESQ., F.R.S.

"I do not hesitate to affirm, that no deleterious substance is employed in ALLSOPP'S PALE ALE and BITTER BEER, and that my confidence in its wholesomeness as a beverage remains unshaken.——" Green-street, April 30."

ALLSOPP'S PALE OR BITTER ALE

May be obtained in Casks of all sizes from the BREWERY, BURTON-ON-TRENT; and from the undermentioned BRANCH ESTABLISHMENTS :—

LONDON, at 61, KING WILLIAM-STREET, CITY;
LIVERPOOL, at COOK-STREET;
MANCHESTER, at DUCIE-PLACE;
DUDLEY, at the ROYAL BREWERY;
GLASGOW, at 115, ST. VINCENT-STREET;
DUBLIN, at ULSTER-CHAMBERS, DAME-STREET;
BIRMINGHAM, at MARKET-HALL;

At either of which places a list of respectable parties who supply the Beer in Bottles, (and also in Casks at the same prices as from the Brewery,) may at any time be seen.

WATER ONLY REQUIRED!

Moore and Buckley's Patent Concentrated Milk.

"Supplies fresh milk at all times."—Times, September 16th, 1850.—— "It was almost, (if not quite) equal in flavour and quality to milk fresh from the cow."—Captain H. T. Austins, Commander of the Arctic Expedition, H.M.S. Resolute, October 1st, 1851.——"The milk is most admirable. None should go to sea without it."—Captain Ommaney, H.M.S. Assistance, Arctic Expedition, October 25th, 1851.——"The greatest comfort and blessing we had on board our ships in the Arctic Expedition."—Medical Officer's Report to the Lords of the Admiralty, November, 1851.

Preserved in Hermetically Sealed Tins, each tin producing seven times the quantity of new milk.

Moore and Buckley's COCOA AND MILK, and CHOCOLATE AND MILK, are combinations of the Concentrated Milk with the finest Trinidad Cocoa and the choicest French Chocolate, in hermetically sealed tins. These delicious preparations are wholly free from the admixtures so common in the packet Cocoas, and, considering their quality, are equally inexpensive; for example, a BREAKFAST-CUP OF PURE COCOA, COMBINED WITH MILK AND SUGAR, can be had at the cost of a Penny, by merely adding boiling water. The PRIZE MEDAL at the GREAT EXHIBITION was awarded to these preparations for their Novelty, Utility, and Economy; and they were constantly used in the Refreshment-rooms of the Exhibition, giving universal satisfaction.

Moore and Buckley's INFANTS' FOOD is a combination of the Concentrated Milk with pure Farina, and will be found a light and nourishing diet for INVALIDS as well as INFANTS, requiring only boiling water for its instant preparation. The whole of these preparations are under the immediate inspection of Mr. Moore, the Patentee, who was for many years the ordinary medical attendant in London of the Royal Family.

The FINEST FRENCH CHOCOLATES in every variety, made expressly for the subscribers by one of the first Paris manufacturers. These Chocolates, it may be observed, are really French, and are greatly superior to those commonly sold as French, but which are in fact, generally speaking, of English manufacture.

MOORE and BUCKLEY, Ranton Abbey Farm and Works, Staffordshire; and 4, Upper East Smithfield, London; and sold Retail by most of the respectable Grocers and Druggists in Town and Country.

Struve's Mineral Waters. — Royal

GERMAN SPA, QUEEN'S-PARK, BRIGHTON. — STRUVE'S PUMP-ROOM and PROMENADES, offering every facility for taking a course of mineral waters as perfect and beneficial as at the natural springs, are NOW OPEN for the Twenty-eighth Season.

Orders for Struve's Bottled Mineral Waters continue to be executed by GEORGE WAUGH and CO., Chemists to the Queen, 177, REGENT-STREET, LONDON, and by numerous other respectable houses in London and the provincial towns, where a printed account of the waters prepared at Struve's Establishment may be obtained gratis.

CAUTION.—Struve and Co. have not the remotest connexion with parties advertising waters under the general name of "Brighton Seltzer," "Brighton Fachingen," etc.; and they beg to state, that every bottle of Struve's Mineral Waters has a red-ink stamp over the cork, having the words, "Royal German Spa, Brighton," under the Royal Arms, and on each side the signature of "Struve and Co."

Francis L. Puckridge, Sole Inventor

and Manufacturer of the late Mr. R. LISTON'S WATERPROOF TRANSPARENT ISINGLASS MEMBRANE PLASTER, patronised and used by Mr. Liston's successor, Mr. J. M. Arnott, in University College Hospital; also by Mr. W. Fergusson, King's College Hospital, and Mr. Wormald, Bartholomew's Hospital, and in their private practice; most valuable for amputations and serious wounds, requiring observation without exposure to the air.

F. L. P. begs to state, there are three qualities, the third not being sufficiently strong for amputation, but of the same properties, and is particularly beneficial for strains, sprains, or any weakened part. Also, Plain Membrane or defensive skin, to apply between the wound and the lint, and causes less pain in dressing. Likewise, a superior Gauze Lisse, of the same adhesive properties as the Membrane, and nearly as waterproof. Also, a White Gauze Lisse, not waterproof, much used in the above-named Hospitals, also on black silk and cotton. F. L. P. offers his most grateful thanks for the encouragement and kind patronage he has received from the Medical Gentlemen of England and foreign parts, and hopes to merit a continuance of their favours by manufacturing his Plasters with the same unremitting care as heretofore.

May be had of the Proprietor, who has removed from 3, Dobson's-terrace, Kennington, to 4, York-place, Walworth, Chemists, Surgical Instrument Makers, &c., with improved directions how to apply.

Clerical, Medical, and General Life

ASSURANCE SOCIETY. Established 1824.

Empowered by Act of Parliament, 1850.

Persons of all ages, and in every station, may assure with this Society on moderate terms, and the assured can reside in any part of Europe, the Holy Land, Egypt, Madeira, the Cape, Australia, New Zealand, and in most parts of North and South America, without extra charge.

FIFTH DIVISION OF PROFITS.

The FIFTH BONUS was declared in January last, and the amount varied with the different ages, from 24½ to 55 per cent. on the Premiums paid during the last 5 years; or from £1 to £2 10s. per cent. per annum, on the sums assured.

The small share of Profit divisible in future among the Shareholders being now provided for, without entrenching on the amount made by the regular business, the ASSURED will hereafter derive all the benefits obtainable from a Mutual Office, with, at the same time, complete freedom from liability, secured by means of an ample Proprietary Capital—thus combining, in the same office, all the advantages of both systems.

A copy of the last Report, setting forth full particulars, with a Prospectus, can be obtained of any of the Society's agents, or by addressing a line to GEO. H. PINCKARD, Resident Secretary.

99, Great Russell-street, Bloomsbury, London.

N.B.—A Fee of One Guinea is allowed by this Society to the Medical Attendants of persons proposing to assure, in all cases in which their advice and information are required.

The New Equitable Life Assurance

COMPANY.

(Incorporated by Act of Parliament, 7 and 8 Vic.)

POLICIES INDISPUTABLE.

TRUSTEES.

Sir James Duke, Bart., Ald., M.P. | George James Guthrie, Esq., F.R.S.
William Fergusson, Esq., F.R.S. | Sir Charles Hastings, M.D.

CHAIRMAN of DIRECTORS—Robert Lee, M.D., F.R.S.

DEPUTY-CHAIRMAN—George Beaman, Esq., M.R.C.S.

BANKERS.

The Commercial Bank of London.

SECRETARY—John Thompson, Esq.

CONSULTING PHYSICIANS.

Marshall Hall, M.D., F.R.S.
Chas. J. B. Williams, M.D., F.R.S.
Jas. Arthur Wilson, M.D.

CONSULTING SURGEONS.

William Fergusson, Esq., F.R.S.
J. Ranald Martin, Esq., F.R.S.
Samuel Solly, Esq., F.R.S.

SURGEON AND MEDICAL EXAMINER.

Thomas Wakley, Esq., F.R.C.S., Guildford-street, Russell-square.

STANDING COUNSEL.

Sir Alexander Cockburn.
George Woodyatt Hastings, Esq., Paper-buildings, Temple.

SOLICITORS.

Messrs. Bell, Steward, and Lloyd, 59, Lincoln's-inn-fields.

SECRETARY.

John Thompson, Esq.

The "NEW EQUITABLE" embraces all the advantages of a strictly Mutual Office, with the addition of an ample subscribed capital, forming a *bonâ fide* security for its policy-holders.

POLICIES INDISPUTABLE.

The Policies of this Company being Indisputable they become as readily negociable, in monetary transactions, as any other description of personal property.

INVALID LIVES

Are assured at rates adapted to the circumstances of each case. Every circumstance affecting the health impartially considered.

DIVISION AND APPROPRIATION OF PROFITS.

The whole of the Profits will be Equitably divided annually amongst the holders of Policies issued on the Participating Scale.

MEDICAL PRACTITIONERS.

The Directors acknowledge and consult all duly-qualified Medical Referees as the Medical Advisers of the Company, and uniformly transmit, with the Questions intended to be made the basis of every Official Medical Report, A CONSULTATION FEE OF TWO GUINEAS.

EXTRACT FROM THE DIRECTORS' FIRST ANNUAL REPORT.

"The extent and character of the business transacted, during the past year, by the NEW EQUITABLE COMPANY, have exceeded the most sanguine expectations of its founder and zealous advocates. From the 31st of January, 1851, the date of the complete registration of the Company, to the 31st of January, 1852, inclusive, no less than *four hundred and forty eight* proposals were received and entertained by the Directors. Out of this number of proposals *three hundred and fifty-five* policies were completed, and the remaining *ninety-three* have been either declined, or are not completed. The sum assured on the *three hundred and fifty-five* policies issued by the Company is *One hundred and sixty-eight thousand seven hundred and sixty-five pounds*. The premiums on the policies thus effected amount to *Six thousand and twenty-five pounds two shillings and sevenpence* per annum, the average amount of the policies being nearly *Five hundred pounds*.

These facts afford matter for earnest congratulation to the Directors, the shareholders, and the assured. If the extent of the operations of the NEW EQUITABLE, during the past year, be compared with those of other Companies, it will be seen that there are very few of the oldest Life Offices, even of the first class, which have transacted an equal amount of business. It is demonstrated by the balance-sheets of offices in the best repute, as published from time to time, that after ten, twenty, or even thirty years of experience and consolidation, many of them have not equalled, in the year just ended, the infant labours of the NEW EQUITABLE."

Policies never disputed.

All descriptions of life assurance business transacted, and every facility given for payment of premium.

Prospectuses, forms for proposals, and further information may be had at the Chief Office, or of the Company's Agents.

Chief Offices—449, WEST STRAND, CHARING-CROSS, LONDON.

The Hope Mutual Life Assurance and

HONESTY GUARANTEE SOCIETY.

For the Granting of Life Policies—Guarantees for Fidelity and Honesty in Situations of Trust—Endowments for Children, as well as Adults—Loans on Personal Security—Annuities, Present and Deferred—and Interest on Deposits.

(Incorporated under 7 and 8 Vic., c. cx.)

Guarantee Fund, £100,000.

Principal Department—No. 4, PRINCES-STREET, BANK, LONDON.

LONDON—WEST-END—MANAGER'S CORRESPONDENT.

Mr. B. W. LARA, 14, St. John-street, Adelphi.

THE MEDICAL PROFESSION AND LIFE ASSURANCE.

It has often been remarked as extraordinary, that, while medical men as a class have received a more comprehensive and sterling education than any other in the kingdom, so very few, proportionately with others similarly circumstanced as to pecuniary means, should have availed themselves of the advantages of Life Assurance.

It is true, these are only just now being generally understood: but to whom are they obviously so important as to the hard-working and ill-paid General Practitioner, usually, from the requirements of his profession, saddled with an increasing family from his first start in life?

The principal cause of this seeming apathy is probably from want of leisure to go through the usual preliminaries, of which, perhaps, the most irksome to a gentleman, independently of the time consumed by it, is the appearing before a Board of Directors, and making, as it is by many considered, a too great exposure of private affairs.

With this feeling, Mr. LARA has put himself into communication with one of the soundest and most advantageous offices—"THE HOPE MUTUAL LIFE ASSURANCE and HONESTY GUARANTEE SOCIETY"—the Directors of which, in making him their "Correspondent," have empowered him to receive proposals at his office from assurers in town, and by letter from his Country Clients; such, therefore as henceforth honour Mr. Lara with their instructions, either to Assure their own Lives, or to obtain Endowments for their Children, he will be happy to save all trouble, beyond the communication of their wishes, without incurring the slightest expense except that charged for the simple premium, at the Head Department, 4, Princes-street, Bank, London.

All Policies are Indisputable, except in cases of premeditated fraud.

Mr. Lara trusts he need hardly add, that medical men *are invariably remunerated for their opinions.*

Prospectuses and all necessary information may be had, on application personally, or by letter, at Mr. Lara's Offices, 14, John-street, Adelphi, London.

*** Loans made on Personal Security to the Policy Holders of the Society.

June, 16, 1852.

Prices of Medical Bottles, Best

Quality, at F. and S. WINDSOR'S, 37, BARTHOLOMEW-CLOSE, CITY:—

6 oz. and 8 oz. GREEN, 9s. per Gross.
1½ PHIALS, Plain, 8s.; Moulded, 8s. 6d. per Gross.
The NEW GREEN FLINT, 10s. per Gross.
Washed Ready for Use.

Druggists' Sundries, and every Requisite for the Surgery supplied.

Samples and Lists of Prices forwarded free on application.

For Varicose Veins and Weakness. —

SURGICAL ELASTIC STOCKINGS and KNEE-CAPS, on a New Principle, pervious, light in texture, and inexpensive, yielding a permanent, efficient, an unvarying support under any temperature, without the trouble of lacing or bandaging. LIKEWISE, A STRONG, LOW-PRICED ARTICLE FOR HOSPITALS AND THE WORKING-CLASSES. ELASTIC NET CORSETS of the same beautiful Fabric. ABDOMINAL SUPPORTING BELTS, for both Sexes; those for ladies' use before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instructions for measurement, and prices, on application, and the articles sent by post from the Sole Manufacturers, POPE and PLANTE, 4, Waterloo-place, Pall-Mall. THE PROFESSION, TRADE, AND HOSPITALS SUPPLIED.

ORIGINAL COMMUNICATIONS.

VACCINATION TESTED BY THE EXPERIENCE OF HALF A CENTURY.(a)

By GEORGE GREGORY, M.D.,
Physician to the Small-Pox Hospital.

The practice of variolous inoculation, first heard of at Constantinople, about the year 1700, and promulgated in England in 1721, did not become general in this country until about the year 1750. It was in 1746 that some benevolent individuals founded the Small-pox and Inoculation Hospital. The success of that early measure of sanitary improvement induced the Royal College of Physicians of London, in 1754, to put forward a strong recommendation in favour of inoculation; but it is worthy of note, that one-third of a century elapsed from the first announcement of Lady Mary Wortley Montague's spirited inroad on the routine of medical practice, before the College of Physicians gave to that measure the stamp of professional authority.

From the year 1748 to 1798, variolous inoculation continued to progress in the good opinion of the public throughout this country. In France, however, it never met with any large amount of Royal, public, or professional encouragement. De La Condamine laboured, indeed, to open the eyes of his countrymen to the merits of inoculation, but to so little purpose, that, in 1763, during the prevalence of a variolous epidemic, the enemies of inoculation prevailed on Louis XV. and his complacent Parliament to prohibit that beneficial practice within the walls of Paris.

The inoculation of small-pox was performed with a double object,—first, to banish from the mind all anxiety as to the taking of small-pox in more advanced life, by giving it at once; and, secondly, to insure a mild form of the disease, free, at least, from secondary fever. In fulfilling these objects, inoculation was eminently and undeniably successful. All subsequent anxiety was effectually banished, and the distinct form of small-pox was so universally secured by it, that the deaths by inoculated small-pox, under skilful professional management, did not exceed four, or at furthest five in a thousand.

Variolous inoculation, however, undoubtedly had its disadvantages. To be of any real service, it was essential to practice it in early life, before the character of the infant's constitution could be known. It happened, therefore, but too often, that inoculation lighted up the dormant embers of scrofula, and thus laid the foundation of evils scarcely less deplorable than the unrestrained ravages of small-pox.

From 1748 to 1798, the physicians and surgeons of this country studied inoculation diligently; but it was not until the latter epoch, when the practice had been tested by the experience of half a century, that the merits and demerits of the measure were fully understood.

In 1798, Jenner published his first Treatise on Vaccine Inoculation. The advantages of the new practice were at once loudly and confidently proclaimed. In July, 1799, ere the sheets which first announced the brilliant discovery were well dry, thirty-three of the most eminent physicians, and forty of the most distinguished surgeons of the Metropolis, including the honoured names of Halford, Baillie, Clive, Cooper, and Abernethy, had signed a document, purporting, "that those persons who have had the cow-pox are perfectly secure from the future infection of the small-pox."(b)

(a) Read before the Medical and Chirurgical Society of London, March 9, 1852.
(b) See Baron's Life of Jenner, Vol. I., p. 354.

The claims put forward by Jenner, in favour of vaccination, in his first Treatise (April 1798) were singularly modest, and such as may now well command our unqualified approval; but on the 17th March, 1802, he announced to the House of Commons, and to the British public, first, that "vaccination is attended with the singularly beneficial effect of rendering, through life, the person so inoculated perfectly secure from the infection of small-pox;" and, secondly, that "vaccination had already checked the progress of the small-pox, and, from its nature, must finally annihilate that dreadful disorder."(a)

When we look around us,—when we observe the quantity of small-pox, now (at the close of the first half century from the promulgation of vaccination) diffused through this and other countries,—when we see the practice of re-vaccination almost universal on the Continent of Europe, and greatly increasing in this country, we are led irresistibly to the conclusion, that these broadly urged claims in favour of vaccination have not been substantiated. Small-pox does invade the vaccinated, and the extirpation of that direful disorder is an event as distant now as when it was first heedlessly (and, in my humble judgment, most presumptuously) anticipated by Jenner.

As in the case of variolous inoculation, so in the case of vaccine inoculation, half a century must elapse before the merits and the shortcomings of the measure can be justly appreciated. 1852 has come, and with it the completion of half a century since Jenner petitioned Parliament for national remuneration. On the present occasion, I propose to test vaccination as Sir Gilbert Blane, in the Fourth and Tenth Volumes of the "Transactions" of this Society, formerly tested inoculation, and to offer the results of a dispassionate investigation.

In the outset of the inquiry, it behoves me to fix what I understand by vaccination, whether something prophylactic of small-pox, or something identical with small-pox. Cow-pox is a disease *sui generis*, so essentially and specifically distinct from small-pox, that it cannot be said with any truth, that he who has undergone vaccination has undergone small-pox in a mild form. The well-known experiments of Ceely prove undeniably that a certain relationship subsists between cow-pox and small-pox; but it must always be borne in mind, that though the variolous miasm, by passing through the body of the cow, is transformed into cow-pox, cow-pox has never, in its turn, been converted into small-pox. Cow-pox and small-pox are, at all times and in all countries, clearly and readily distinguishable. The ordinary source of cow-pox is not that virus obtainable by artificial means, but it is, as Jenner truly stated in his Petition to the House of Commons(b), "a disease which occasionally exists, in a particular form, among cattle."

A clear understanding of this question becomes essential, when it is attempted to institute a comparison between the results of inoculation and vaccination,—an attempt which is now made by every writer on the subject.

The object of inoculation was to give the disease of small-pox, not to prevent it. The object of vaccination is to prevent small-pox, not to give it. To compare recurring small-pox, therefore, with small-pox after vaccination, is to compare things, not merely different from each other, but opposed in their spirit and scope. When a person inoculated in childhood contracts small-pox in adult life, he undergoes small-pox for the second time; but, when a person vaccinated in infancy takes small-pox in adult life, he takes it for the first time. Every such person is, no doubt, liable to a second attack of genuine small-pox. Whether this contingency, however, is to be dreaded, the following observations will tend to show.

(a) See Baron's Life of Jenner, Vol. I., p. 490.
(b) Ibid., p. 491.

It has been the fate of recurrent or secondary small-pox to be, for the last 100 years, the battle-field on which the abettors of inoculation, the enemies of inoculation, and the uncompromising supporters of vaccination, have taken their stand. To encourage the practice of inoculation, De La Condamine declared, that not one person in 10,000 ever took small-pox a second time. To rebut this argument, the enemies and lukewarm supporters of inoculation collected cases of secondary small-pox (especially of small-pox after alleged inoculation) from all quarters, gave credence to every idle tale that was told them, and to an eager desire of victory sacrificed all considerations of scientific accuracy. The case of Louis XV. was put prominently forward. That renowned monarch was stated to have undergone small-pox in 1724, when 14 years of age, and to have died of a second attack, fifty years afterwards. Modern historians (having no favourite doctrine to support) have ruined this celebrated case. The King's disease, in 1721, was a sharp, though brief, attack of fever. Louis XV. is known to have lived afterwards in constant dread of small-pox. In 1752, when his son, the Dauphin, took small-pox, the King refused to go near him. This monarch's distrust of inoculation was fearfully chastised by his own death, under the most aggravated attack of confluent and gangrenous small-pox, on the evening of the 10th of May, 1774, being the eleventh day of fever, and the thirteenth of eruption.

To explain, or palliate, the alleged imperfections of vaccination, modern writers almost universally enlarge on the frequency of recurrent small-pox; and this is done by those high medical authorities to whom Parliament assigns the superintendence of vaccination in this country.(a) Some further remarks on the subject are, therefore, demanded.

It is well worthy of record, that the Transactions of this Society, which now extend through a period of forty-seven years, present only one solitary case of recurrent small-pox, —that of Francis Bird, recorded by Dr. Bateman.(b) This case carries with it every reasonable proof of accuracy; but a second instance, imperfectly noticed in the same paper, has no claim whatever on our confidence. The peculiar characters of small-pox, during its advance and decline, are said to preclude all ambiguity as to the true character of the disorder; but the experience of the Small-pox Hospital does not bear out the assertion. Persons are continually brought to that hospital with certificates from medical men, that they labour under small-pox, while the disease proves to be lichen, urticaria, varicella, or ecthyma. The pits and scars, too, so strongly insisted on by some as unequivocal evidences of antecedent variola, cannot always be relied on, as the case of Thomas Davis, narrated by Dr. Hennen,(c) in the *Edinburgh Medical and Surgical Journal*, clearly establishes.

The same volume which records that striking case, contains a long list of authors who have detailed instances of secondary small-pox. Very many of these cases I have carefully inquired into. A large number prove to be mere repetitions, (one author copying from another). Some are so obviously apocryphal, that no credit can be placed in them. While perusing the most trustworthy of these cases, I was forcibly struck by the fact, that they bear no resemblance whatever to the cases of small-pox after vaccination now so common. Some of the attacks were milder than the alleged primary seizure, some severer, many fatal; but the peculiarity of modification, so characteristic of post-vaccine small-pox, is never, even incidentally, alluded to.

In estimating the degree of credit due to the cases of recurrent small-pox recorded by the authors of the last century, let it not be forgotten, that the variolæ veræ, and pusillæ were not accurately distinguished until 1767; and that the identity of these diseases (which Heberden then laboured so diligently to disprove) was revived, as a pathological doctrine, by Dr. Thomson, of Edinburgh, in 1819.

While such important differences of opinion exist, it is obviously essential, that the details of both attacks should be carefully given. These, however, are scarcely ever forthcoming; nor do I remember to have read one authentic case where the same medical man witnessed both the primary and the secondary seizure. It would be absurd to argue against the possibility of such an occurrence. I have, myself, known a few unequivocal instances; but I am, at the same time, thoroughly convinced, that the recurrence of small-pox is among the most rare events which the annals of medicine furnish.

These views I would now contrast with the occurrence of small-pox after vaccination, premising that, in my judgment, the two events are traceable to different causes, and have no pathological bearing upon each other whatever. Small-pox occurring after vaccination should be investigated simply with the view of determining under what circumstances the sequence takes place, to what extent it takes place, and in what degree of intensity.

The records of the Small-pox Hospital, during the last eleven years, (that is, since the prohibition of inoculation,) throw much light on these subjects. Appended to this paper are Tables, giving minute statistical details of the movements in the hospital during that period, and specially in the years 1850 and 1851, of which the following may be taken as a summary:—

During the last eleven years, 4091 persons have been admitted into the hospital having small-pox, of whom 2167 had been vaccinated, and 1924 were unvaccinated; that is to say, considerably more than one-half of all the cases admitted had been subjected to vaccination in early life. By far the larger proportion of this section of patients were of adult age. A few were between the ages of 9 and 15; but below the age of 9, scarcely any vaccinated person, having small-pox, was admitted. This could not be accident, for numerous cases of unvaccinated children, under 9, were admitted. I am, therefore, driven to the conclusion, that the susceptibility of the variolous miasm, among vaccinated persons, increases as life advances, the reverse of what happens in the unvaccinated portion of mankind, where the susceptibility of small-pox is greatest in infancy.

In the two years 1850 and 1851, the total number admitted (having small-pox) was 976, of whom 162 died, being at the rate of 16 per cent. In this number were comprised 11 infants below the age of 5 (all unprotected), of whom 22 (or more than one-half) died. 161 were children between the ages of 5 and 15 (the greater portion unvaccinated), of whom 25 died. 685 were adults from 15 years of age to 30. 109 exceeded the age of 30. The larger proportion of these 791 adults had been vaccinated; of them there died 115, or 14 per cent.

Of the total number admitted (976), 613 professed to have been vaccinated in early life, and of them 569 exhibited cicatrices more or less distinct. Of this latter section (the vaccinated with cognizable scars), there died 25, being in the ratio of 4 per cent. Seven persons professed to have undergone small-pox at some former period, but the corroborative evidence was deficient.

The proportion of persons admitted after vaccination to the total admissions, amounted in 1851 to 65 per cent. It was only 44 per cent. in 1811. The increase is obviously attributable to the more extensive diffusion of vaccination. Whether the proportion of vaccinated subjects taking small-pox in adult life to those who remain unaffected has, or has not, yet attained its maximum, I am not prepared to say, nor can I venture to express the existing ratio in figures. Every one must form his own judgment on this matter, by observing what has happened among his own relatives, friends, neighbours, and acquaintances. That the proportion is infinitely beyond anything which had been anticipated forty, or twenty, or even ten years ago, is, I conceive, undeniable.

With regard to the intensity of the disease when so occurring, we have means of arriving at much greater accuracy of detail. The mortality at the Small-pox Hospital during the last two years, among the well-vaccinated section, has only slightly exceeded 4 per cent., though it must be acknowledged, that many suffered most severely, (especially in the early periods of the disorder,) and though secondary fever, with its sequelæ, was not unfrequent. Those who refer so triumphantly to the bills of mortality, as evidences of the value of vaccination, should remember the essential differences between quantity and intensity.

With such varied data before us, what estimate can we form of the real merits of vaccination? and what measures can be suggested, having for their object an increase of public security against the ravages of small-pox?

The experience of half a century abundantly demonstrates, that small-pox, though it has been largely and most beneficially (and may be still further) controlled, will always

(a) See Report of National Vaccine Board for 1851.
(b) Medico-Chirurgical Transactions, Vol. II., p. 31.
(c) See *Edinburgh Medical and Surgical Journal* for October, 1818. Vol. XIV., p. 461.

abide among us; and that the notion of extirpating it was absurd and chimerical. The same amount of experience teaches, that the absolute mortality by small-pox throughout Europe has been, through the agency of vaccination, diminished to a most astonishing extent. But, while freely admitting this, and acknowledging the immense benefits which have accrued to mankind from the splendid discovery of Jenner, we are constrained, at the same time, to admit, that vaccination fails in that great object which inoculation so effectually attained,—establishing in the mind a feeling of security.

A large number of the vaccinated portion of mankind, especially in the higher classes, live now in constant dread of small-pox. They fly from it on the first notice of its being in the neighbourhood, and could by no effort be persuaded to visit the wards of the small-pox hospital. Others, again, are satisfied with that limited amount of protection which vaccination really affords,—are content to know, that their children, if succumbing to small-pox in adult life, will, in all probability, have it lightly; and are no further anxious to escape small-pox than they are to escape, as far as may be, measles and scarlet fever. To minds so constituted (and many such I know), vaccination appears in its true and just colours,—a beneficent provision of Nature, not for the extermination, but for the mitigation of small-pox—admirably adapted, by its mildness, for the infantile constitution, and specially fitted for that early period of life, when the susceptibility of casual small-pox is most energetic. The warmest friends and admirers of Jenner may surely rest contented with such brilliant results as these, proved as they are by the concurrent voice of mankind, and sanctioned as they are by the "experience of half a century."

But such laurels are insufficient for certain ultra-supporters of vaccine power. Not content with the high position which their favourite measure has justly attained, they speak and write in the most disparaging terms of variolous inoculation, —they cry down and brand as an enemy of the human race every man who claims for it its fair share of merit. They load it with obloquy, as being the means by which small-pox is kept up and disseminated throughout this and other countries. Against such unjust accusations, I shall never cease to raise my voice; and I proceed shortly to state, on what grounds I base my opposition to these extreme views, and to this desertion of a useful and once popular measure.

Inoculation was abolished throughout England and Ireland by Act of Parliament, in 1840. The Act has been rigidly obeyed in every part of the country, excepting, perhaps, the more distant regions of Connaught. Nevertheless, small-pox is just as prevalent now as before the Act of 1840 was passed. The prohibitory clause of that Act has not affected, in any the smallest degree, the quantity of small-pox,—a circumstance, the explanation of which is obvious enough to those who will banish prejudice and reason with candour.

The Act which prohibited inoculation did not render vaccination compulsory. Numbers, therefore, remain, as the pabulum whereon small-pox may prey. Every child taking small-pox casually, becomes the focus of contagion, more dangerous than the same child would have proved, if inoculated, in the exact proportion that casual small-pox exceeds inoculated small-pox in severity. A mild case of inoculated small-pox, (which dries up and scabs on the seventh or eighth day,) is innocuous, when compared with a confluent case, which pours forth a virulent secretion for three weeks. One such case does infinitely more mischief in a densely populated neighbourhood than ten or twenty cases of a mild inoculated small-pox. For all purposes of public security in the Metropolis, it is far better that 100 children should be inoculated, than that twenty should remain unvaccinated, the easy and certain prey of confluent casual variola. This view of the question appears to have altogether escaped the notice both of our legislators and our pathologists. If, therefore, the Legislature cannot or will not enforce vaccination, it is better that the restriction on inoculation should be in some measure removed. No real improvement can ever take place in this country, with reference to small-pox and its antidote, until the present anomalous state of the law is altered.

When inoculation was abolished, parents should have been compelled to give to their unconscious offspring the benefits of vaccination at that period of life when those benefits are most unequivocally manifested. To permit such children to imbibe the germs of small-pox in its most malignant form, and thus to disseminate it, yet withhold from them the great boon of inoculation, was a great error, of which we are now reaping the bitter fruits.

That matters cannot long continue in their present unsatisfactory state, must, I apprehend, be universally conceded. Sooner or later Parliament must reconsider the Act of 1840, and either simply make vaccination compulsory, or couple with it a repeal or modification of the clause prohibiting inoculation. I do not venture to anticipate the decision of the Legislature on a question of such national importance; but I am firmly persuaded, that the unqualified prohibition of inoculation was ill-judged, and that Parliament would have acted more wisely in placing that practice under restriction, than in abolishing it altogether. Such restrictions might be more or less stringent. Inoculation would, as a matter of course, be practised exclusively by medical men. Its adoption by others would, doubtless, remain, as at present, punishable by fine and imprisonment. The exposure of all persons labouring under small-pox, and their removal in any other vehicles save those licensed for that special service, would, I trust, be made equally misdemeanours.

But the restrictions on inoculation might, if Parliament thought fit, be extended much further than this. It might be strictly prohibited to inoculate children under five years of age. Inoculation might be permitted only to persons of mature age, capable of judging for themselves. It might be conceded only in the case of persons who had previously undergone vaccination. It might be allowed only in houses licensed for that especial object. No one can reasonably object to judicious restrictions on a practice which was once grossly abused; but it is one thing to root up a tree, and another to lop off defective branches. Should the Legislature permit a qualified and restricted inoculation, I have no doubt that the larger portion of our population would remain satisfied with the mild and safe process of vaccination, while some would prefer that measure which, occasioning a greater amount of immediate, yet diminishes, or, rather, abolishes, all prospective anxiety. The judgment of the medical Profession would, in every such case, be necessarily appealed to. Educated as the present race of medical practitioners are, and acting, as they would act, under the supervision of a discerning Press, both public and professional, I feel assured that they would exercise that judgment with due care and circumspection, and that the result would tend greatly to the benefit of the country.

THE MECHANISM OF BRONCHOPHONY.

By W. H. WALSHE, M.D.,

Professor of the Principles and Practice of Medicine, University College, London; Physician to University College Hospital; Consulting Physician to the Hospital for Consumption, etc.

[Concluded from page 462.]

§ I. To return for a moment to the question of the relative conducting powers of healthy and hepatised lung. Skoda, it will be remembered, (*Vide ante*, P. 460, col. 2,) assumes that the alleged temporary disappearance of bronchophony over hepatised tissue depends on passing obstruction of the tubes with fluid secretion. Now, here, he conceives, is an argument against Laennec's doctrine of increased conducting power in hepatisation; for "were such increase of power real, it would be a matter of indifference, whether air or fluid were contained in the bronchial tubes." But, observe the constitution of this argument. Skoda assumes the presence of a certain *doubtful* condition, (namely, a change in the relationship of air and fluid in the tubes of the hepatised tissue) in order to explain what is itself another *doubtful* condition (namely, sudden disappearance and reappearance of bronchophony;) and then bases an argument against Laennec, on a combination of the two assumptions. But, taking the proposition on its own merits, what force has it? Is it true that, on the doctrine of increased conducting power, it makes no difference, whether one portion of the series of conducting media be fluid or air? Obviously the *onus* of proving the fact, if it be a fact, rests with Skoda; meanwhile, we are justified in believing, that such partial variation on the composition of the conducting materials does exercise a certain influence on the general result.

Again: Let us suppose a case of hepatization of a tolerably thick stratum of the *posterior* part of a lung; bronchophony is heard, in such a case, at the posterior, not at the anterior, surface of the chest. Now, as, according to Skoda himself, reinforcement of voice would, under the circumstances, take place about the central tubes, how comes it, if his notion of the superiority of healthy over solidified tissue (as a conducting material) be constantly correct, that bronchophony is not heard in front over healthy texture, instead of being, as it is, audible in the back, over the hepatised parts?

§ II. There is a well-known principle, differing both from consonance and echo, in virtue of which sounds are increased in intensity, namely, the *unison-resonance of cavities*. This principle is brought into action in a variety of instruments; all those of the violin kind, the piano-forte, etc. *Every note* produced from the sounding material of such instruments is reinforced by the mass of air enclosed within them, — not alone *certain notes and their harmonics*, as where consonance is the reinforcing principle in action. Now, there can be little doubt that, in the natural condition of the chest, this principle of *unison-resonance* comes into play. But it is totally unavailable in the explanation of the bronchophony of hepatization, for the simple reason, that such *unison-resonance* is perfect exactly in proportion to the *amount of air contained in the resounding space*. Imagine the box of the violin filled with any solid or fluid material, and what comes of its property of reinforcing sound?(a)

Had this principle any influence in the generation of the bronchophony of pneumonia, its effect would obviously be to transfer the phenomenon to the healthy side of the chest, in cases where the solidification was limited to one lung.

§ III. I have within the last few days observed a fact of considerable interest in its bearings on the general question of reinforcement of sound within the thorax. In a case of well-marked chronic consolidation of the apex of the right lung, *the second sound of the heart* (this organ, the arch of the aorta, and the pulmonary artery being, as far as ascertainable from signs and symptoms, perfectly healthy) *was decidedly louder under the right clavicle than at the mid-sternal base*. No such reinforcement existed at the sternal notch, nor under the left clavicle; the mediastinum and left apex were, judging from the percussion-note, free from solid matter. Here, then, was a case where the second sound was louder at about three inches' distance from its point of production than at that point itself; the pitch of the sound in the two places was identically the same. Was the reinforcement produced on the principle of echo, consonance, or unison-resonance? Certainly not on the last, probably on the first, of the three.

§ IV. To resume the question of altered pitch. That the voice should, in travelling from one spot to another, undergo alteration in pitch, seems, on first thought, opposed to the commonest experience and to the recognised laws of acoustics. And in experimentally investigating the point, there are some easy sources of fallacy. Bronchophonic voice may be muffled and husky, while the laryngeal tone is pure; and the quality of the two may be essentially unlike. Now these differences may readily, unless great care be taken, be confounded with differences in pitch. Fully alive, however, to the possibility of such deception, I have endeavoured to guard against it; and am persuaded, that the pitch of the bronchophonic voice does sometimes irregularly differ from that of the laryngeal. How, then, is the difference explicable? Conceivably (1) by the production of a new note within the chest chiming in within the laryngeal; or (2) by change of laryngeal note during conduction through *varying* media in the thorax.

(1) The production of new note within the chest is possible by unison-resonance, by consonance, and by echo. But the very name, *unison*-resonance, shows that this principle cannot be employed in explanation, when difference of pitch is concerned. Nor will the principle of consonance serve us either. For, though it is true that under favouring circumstances a note differing in pitch from the original one may be generated by consonance, that different note is always an harmonic of the original tone. Now, the difference of pitch we have under consideration is irregular and non-harmonic. Nor will echo help us through the difficulty; for, though an echoed sound may differ from its original in intensity and duration, and, by possibility, even in quality, it always agrees with it in pitch.

2. We are driven, then, to the phenomena of conduction though varying media for release from our difficulty. And though it would probably be impossible to *prove* that the change in pitch is thus actually effected in the chest, there is strong argument in favour of this mode of agency.

Thus (it appears from an experiment of Savart) "let a long flat glass ruler or rod, connected with mastic to the edge of a large bell-glass, perpendicular to its circumference, be very lightly supported in a horizontal position on a bit of cork, and then let the bell-glass be set in vibration by a bow, at a point opposite the place where the rod meets it. . . . In this combination *the original tone of the bell-glass is altered, and the note produced differs both from that yielded*

(a) Every schoolboy knows the increase of tone given to the sounds of the Jew's-harp by placing it in the ordinary position for playing, within reach of a resounding cavity,—the mouth; and there are few who have not accidentally learned the hopelessness of attempting to play, if the said cavity happen to be filled with eatables.

by it, or by the glass rod vibrating alone."(a) Again, Odier long since ascertained, that if hydrogen be breathed, the voice is *raised in pitch.*(b)

Now, here are facts showing that pitch may be modified by conduction from one kind of vibrating solid to another, and that the pitch of sounds is controlled by the nature of the gases in which they are produced. The application of these facts to our subject is sufficiently obvious; and, curiously enough, the inferences to which they lead on the question of altered pitch, lend indirect support to Laennec in assigning the importance he does to conduction.

§ V. Finally, the phenomenon of bronchophony seems to be a resultant essentially of conduction and echo; in a secondary degree, perhaps of consonance; and in very rare instances (possibly, for example, in emphysematous rarefaction) of unison-resonance of the thoracic cavity. There are, besides, some subsidiary conditions, the influence of which cannot be doubted; viz., the density of the gases in the thorax, their composition, their temperature, and the quantity of fluid in the tubes.

But, even with the aid of all these conditions, there are some peculiarities of voice-resonance inexplicable. How happens it, for instance, that, in the great majority of persons, the voice naturally resounds much more forcibly under the right than the left clavicle?

ON THE PATHOLOGY OF ONE FORM OF ENCYSTED EMPYEMA.

By EDWARD LATHAM ORMEROD, M.D.,

Caius College, Cambridge; Fellow of the Royal College of Physicians; Physician to the Brighton Dispensary.

There are certain differences to be observed in the products of inflammation of the same part in different individuals. Repeated observation on a very extended scale (c), has shown, that these differences may be grouped into classes characterised as much by the differences of the constitution of the patient as by those of the local morbid products. It is inferred that the constitutional are the causes of the local peculiarities. At least within certain limits.

I do not wish to enter generally into the discussion of these pathological principles. My opportunities of observation have given me nothing to add to the principles themselves, as they have been laid down for us by more than one pathologist (d) of our own country. I would only, as the nature of my opportunities has rather enabled me, endeavour to illustrate their practical application to particular subjects.

I have spoken, on another occasion (e), of the distinctions of this kind which may be traced in the varying form of those fibrinous masses which are found on the valves of the heart in so many cases of valvular disease of this organ; and of what share the original elementary constitution of this deposited or exuded matter may have had in determining the occurrence of one or the other form. I would here, in the same way, trace the application of these pathological principles to inflammation of the pleura, and more particularly to one form of what is familiarly known as circumscribed or encysted empyema.

The subject requires but few introductory remarks. The changes which ordinary fibrinous exudation undergoes, and its ordinary appearance and properties, are well known. It is effused as a fluid which hardens and contracts, displaying a fibrous texture, from whence its name. Still, in course of time, it hardens and contracts more and more, till it assumes the form and properties of ordinary fibro-cellular tissue, and, under favourable circumstances, at last disappears altogether. But, sometimes, the same parts, whose ordinary inflammatory exudation is as above described, yield a fluid which, from the first, rather resembles pus than fibrin; and a serous cavity, under such circumstances, is filled with opaque, loose, curdy masses. Or, sometimes, though the matters exuded may differ but little in their more obvious characters, and on their first appearance, from ordinary fibrin, yet a more particular examination of their structure and their further progress brings into view some very essential differences. For they are, even in their most compact state, rather granular and friable than tough and fibrous, and their tendency is to soften rather than to harden and contract. And, as this tendency may take effect long after the masses have entered upon a comparatively independent state of existence, such effect would seem to depend on the development of integral properties, innate and inherent in the inflammatory products. Such, generally, are the changes which may ensue in the products of inflammatory fibrinous exudation of the ordinary and the abnormal form respectively.

Many names have been given to this ill-conditioned fibrin. The distinctions between healthy and unhealthy coagulable lymph seem, however, to be most appropriately expressed in terms of their microscopical or more obvious physical character respectively, as the fibrous and granular varieties of coagulable lymph. The granular or corpuscular variety corresponds to Rokitansky's crönpos and Dr. Williams's cacoplastic species.

In speaking thus generally, however briefly, of the secondary changes which inflammatory exudations undergo, it might seem necessary, at least, to allude to that variety of exudation which undergoes no further changes at all. With this we have a complete series,—the plastic, the cacoplastic, and that which undergoes no change for either good or bad, the aplastic. It is indeed necessary to mention this as a possible source of fallacy. For perhaps, in the following cases, the particular examples selected to illustrate the intermediate stages may really have been instances of a stationary and not of a progressive form of disease. Beyond this possible fallacy, which, however improbable, it is yet necessary to keep in mind, the existence of this form of exudation is beside the present question.

It appeared necessary to preface the following cases by these very general remarks on the intimate nature of the secondary processes. Few can doubt that, in examining into these processes, in studying the blood as much as the bloodvessels, and recognising independent properties inherent in organic products, modern pathology has made a most important step in advance of the past generation. Still, it is in our proofs and absolute knowledge, rather than in our views, that this great advance has been made. For one cannot read the remarks of those who have written on inflammation, without feeling that such expressions as the concoction of pus, and so on, were not unmeaning terms to them. Whatever theories may have been involved in this terminology in older times, and, in later times, whatever vague sense may have been generally attached to it, to the deeper thinkers, at least, it expressed the occurrence of that series of integral changes, in which they believed, with as firm conviction, and on grounds as sure (save the microscopic evidence) as we do at the present day.

The morbid appearances described in the narrative of the following cases are probably familiar to all. We are all probably well acquainted with those large gelatinous masses of fibrin which are found, at various periods after the occurrence of inflammation of the pleura, lying at the bottom of its otherwise obliterated cavity; and all who are in the habit of examining dead bodies have probably met with circumscribed collections of pus in the same situation. I think that I have met with both these appearances, and with what seem like intermediate conditions, sufficiently often, in a close succession and under similar circumstances enough to justify me in regarding them as the successive stages of one morbid process, and in presenting the three following cases as a series illustrative of the same. In other points of view, also, these cases were very interesting; but it has appeared better, for the sake of greater clearness and brevity, to suppress the notice of all particulars foreign to the present purpose.

Case I.—A man, aged 28, the subject of discharge from the left ear, with severe cerebral symptoms, died of double pneumonia. On examination of the body, the pleura covering the upper lobes was found free on both sides, save an adhesion of recent fibrin on the axillary aspect of each lung. The right lower lobes were universally closely adherent by fibro-cellular tissue; and so was the left lower lobe also, except in the interlobar fissure, and in the angle between the diaphragm and the walls of the chest posteriorly. The

(d) I believe that I need scarcely do more than mention the names of Mr. Paget and Dr. C. J. B. Williams. To Vogel's Pathology, by Dr. Day, and Hewson's Works, by Mr. Gulliver, in themselves, and for their references to other sources of information, I am likewise very much indebted.
(e) Gulstonian Lectures, *Med. Gaz.*, Vol. XLVII., Lecture II.

interlobar fissure was occupied by a gelatinous-looking mass of fibrin, which had contracted scarcely any adhesion to the neighbouring surfaces. In the angle between the ribs and diaphragm lay a flattened cyst, containing about 15 oz. of a fetid, puriform fluid. The walls, thickest round the edge, were constituted by a compact layer of friable fibrin lined with adherent pus. The lung in the neighbourhood of the cyst had a gelatinous appearance, from the infiltration of serous fluid; and the anatomical characters of pneumonia were lost at this point, ceasing at some lines' distance from the walls of the cyst, which were very firmly connected with both the visceral and parietal layers of the pleura. There were no tubercles in the lungs.

The morbid appearances in the following case supply an important link connecting the two stages of the morbid process under consideration described in that just detailed:—

Case 2.—A woman, aged 23 years, died of fever, twelve months after having received a blow on her side, to which accident she used always to refer the constant pain and cough which she had suffered ever since. On examination of the chest after death, the right pleura was found free; the left (the side of the injury) was universally adherent; in front, by loose, easily separable agglutination of the two pleural surfaces; behind, by a layer of fibro-cellular tissue, which was of uniform thickness and consistency throughout, except at the lower part: here it contained within its substance, nearer to the pulmonary than to the costal surface, a mass of gelatinous-looking fibrin, fully a quarter of an inch thick. This mass shaded off on the sides gradually into the substance of the false membrane in whose interior it lay; but was bounded by a tolerably distinct ring round its edges, at the line where the two layers of the false membrane diverged, as it were, or re-united to enclose it. It was of a flattened oval form, measuring about 7 by 3½ in., and crossed without entering the interlobar fissure. A few tubercles were scattered through the apex of the right lung.

If I am right in referring the masses found in the obliterated pleural cavities in both these cases to the same morbid process, they would stand in the following order:—In *Case* 1, in the mass of fibrin which occupied the interlobar fissure, we have an example of the earliest form of this series of morbid appearances. The mass had contracted scarcely any adhesions to the neighbouring parts; it was of almost uniform consistence within and without alike; it had all the appearance of having been recently deposited; and, if we must assign it a date, it would seem most likely to have originated with the recent fatal attack of pneumonia. *Case* 2 takes up the history a little further on. After about a year had elapsed from the probable period of the deposition of the mass, we find that it had contracted adhesions, and become hard and tough on the surface, though within it still closely resembled the structure of the more recent product in the previous case. *Case* 1 takes up the history of the morbid changes again, after a long but uncertain interval. The mass, in the angle between the ribs and diaphragm, which illustrates this stage, now contained no longer a gelatinous fibrin in its interior, but a diffluent puriform matter, which waited only an opportunity to discharge itself. The case next following, where the discharge of the contents of the cyst was attended with fatal consequences, completes the history of the internal changes.

Case 3.—A man of middle age, of strumous constitution, working hard and living carelessly, had a severe attack of "inflammation of the left side." But he got apparently well, and so continued for about seven years. Then he began to fail; he suffered from cough, and had that peculiar appearance which we so often see in the subjects of aneurism of the arch of the aorta. Nothing, however, could be determined by repeated most careful examination, as suggested by this particular appearance, beyond comparative dulness and impermeability of the left side of the chest. He got rapidly worse. With the aggravation of the symptoms the case became more clear. Evidence was obtained of perforation of the lung; and he died, with the physical and other signs of partial pneumo-thorax of the left side.

Omitting the description of other changes not relating to the present subject, there appeared, on dissection, almost universal adhesion of the left pleura. The pulmonary and costal surfaces were closely united by dense, firm tissue, except for about a hand's-breadth over the lower lobe behind. To this extent the two layers were separated by a collection of thick, curdy, puriform fibrin. The sac communicated, through the substance of the lung, with a neighbouring bronchial tube, by a small, well-defined orifice. A very few small tubercles were scattered through the substance of the lungs.

In this case the more urgent feverish symptoms, and, indirectly, those leading to the fatal termination, appeared clearly referable to the pointing, so to say, of this collection in the pleura. Quoting it as a very rare though very striking case, I need not fear lest I should be thought to overrate the probability of a similar occurrence. Such cases are very rarely met with thus painfully complete. And this one has not been cited to mark how severe the symptoms may be when they do occur, so much as to show for how long a time the process on which they depend may be delayed. For this delay is not more characteristic of such rare forms of disease than of the more ordinary cases, where the collection points externally, and, during life, can only by contingent physical signs, and by the previous history, be distinguished from a common subcutaneous abscess in the same situation.

To the anatomical history of the form of empyema, exemplified in the above cases, there is little to be added. The successive morbid appearances tell their own story very clearly. There are some points in its pathology, however, which (studying, in the same way, one case by the help of another) seem to be better illustrated by the details of the following case, drawn from a different form of the disease:—

Case 4.—A man, presenting nothing particular in his general condition to forbid the operation, underwent amputation of the thigh. Pleurisy set in on one side; and, after some days (as far as physical signs can be trusted), on the other also. On examination after death, the pleura, which, there was reason to suppose to have been first attacked, was found to be coated with fibrin of the ordinary character. The cavity of the opposite pleura contained curdy, puriform flakes, floating loose in turbid serum. As if it were not till the second pleurisy set in that the change in the patient's condition, revealed in the differing nature of these products, manifested itself.

Less striking illustrations are of daily occurrence in the contrast between the tough fibrin effused in the commencement of pleurisy or pericarditis, and the soft, puriform products of recrudescent inflammation which infiltrate the meshes of the older tissue; and other similar instances will readily suggest themselves. But, in cases of such a kind, the question of the influence of the earlier on the later organic products will recur. And it is only in observations like that just detailed, where the different products are separated, that such a fallacy can be excluded. Only so can we be assured, that the difference of the later product is not referrible to the fact of its having been eliminated on a surface of a different nature, on the membrane, namely, which has been formed upon the serous surface during the earlier period of the inflammation.(a)

Considering the usual state of the patients who present this modification of the ordinary process of inflammation, namely, that they are commonly such as have been exhausted by protracted disease, by severe surgical operations, or by parturition, that they are the class where we always fear the formation of aphthæ, or bed-sores; considering this, it is clear, that active inflammation of such a form involves, on all accounts, great present danger. And, if we look beyond this present danger to the cases where it has been surmounted or never threatened, still the future is not without grounds for apprehension even in these. We have to consider the remote effects of a morbid product of this nature having been thrown out in the deep-seated cavities of the body, and in the neighbourhood or even the substance of important organs. For there are dangers connected with its removal from such positions, and its removal is an event much more

(a) There is no reason to question the commonly received opinion, that in the masses resulting from ordinary fibrinous exudation from serous surfaces, the outer layers (that is, those next the parent membrane) are formed first, and the inner layers by transudation through these. But, where the effused matters are incapable of organisation, this rule no longer applies. Thus, in croup, we may find the adventitious membrane which was first deposited raised from the parent surface by a layer of pus, which has subsequently formed beneath it, but which, from its want of a regular organisation, has been unable to traverse it. (See Gendrin's Histoire Anatomique des Inflammations, sec. 806.) It seems probable that the flakes of curdy fibrin which we find sometimes in inflamed serous cavities have been thrown off the parent surface in this way: and this is the best explanation of the little pits which we may often notice on the adventitious coats of the liver or spleen. (See also Hodgkin: Morbid Anatomy, Vol. I., pp. 52, 125.)

probable than the occurrence of the ordinary salutary changes in, or of absorption of, the exuded matters. And the lapse of time gives us no security against these contingent dangers, inasmuch as they are dependent on the inherent tendencies of the mass. Instance *Case* 3, above detailed.

There is another point involved in the pathology of this form of encysted empyema, which may be more clearly displayed by reference to quite a different class of cases. In those already detailed, the results of modification of the products of inflammation cannot well be separated from those of an integral change of the fibrin of the blood independent of inflammation. The following unusual case, however, supplies an illustration of this last occurrence in the most simple and unequivocal form.

Case 5.—A poor, wretched, intemperate man, who had struggled with disease and want, in whom for the last four months the sufferings had more particularly hinged on palpitation and pain in the epigastrium, came into St. Bartholomew's to die, in June, 1848. He was an object of much curious interest during the time that he survived; but no one succeeded in completely unravelling all the physical signs of disease of the heart through the pericardial friction sound by which they were masked.

On examination of the body after death,—passing over other morbid appearances which have no connexion with the purpose for which the case is quoted,—there was found to be very extensive disease of the vascular system. The aorta was rigid from earthy deposit with atheroma. From the right, and in front of the aorta, sprung an aneurismal sac of about two fluid ounces' capacity. This was filled with a dark, imperfectly laminated coagulum, from which a thick, purplish, creamy fluid exuded on pressure, and more of this fluid lay between the coagulum and the sac. About an ounce of a similar fluid was contained in another sac, lying to the right, and rather in front, of the pulmonary artery, and apparently, but not very distinctly, communicating with the aneurismal sac first noticed. The coagulum contained in this first sac was connected with the recent one found, as usual, in the aorta, by means of a thick white fibrinous mass; and from this again there sprung a rounded process, which, on section, was seen to contain a thick fluid, similar to that usually observed in Laennec's globular vegetations; to which morbid products, indeed, this larger process bore a very exact resemblance.

The evidence of this case, in the particular point, appears to be very important. Here was a most unusual deviation from the ordinary condition of the fibrin in aneurismal sacs. Removed from all surrounding vital agencies, as far as it is possible for any substance still remaining in the body, and retaining vitality, or at least resisting putrefaction, to be, the fibrin had undergone the same changes which we have already traced in the interior of large fibrinous exudations in the pleura. And the cause of this integral change was still more distinctly referred to the fibrin itself, rather than to any influence of the surrounding tissues, by the result of the examination of the more recent coagulum. For the fibrin just newly deposited displayed the same tendency to soften, and the same integral changes, as did that which had concreted long before into the laminæ of the coagulum in the aneurism.

This case is interesting, as bearing on another point of importance to the present subject. Thus, it appears, at first sight, very inconsistent with the definite tendencies argued to exist in nascent fibrinous exudation, that, in a mass believed to be of uniform constitution throughout, the outer layers should undergo the normal, and the inner layers the abnormal, series of changes. In the cases which are the proper subject of this paper, to obviate this apparent inconsistency, we may admit of a difference of composition, and suppose the outer layers to have been formed first, before the peculiarities, constitutional or local, as the case might be, which determined the nature of the later exudation were called into action. But, in the case just detailed, we may trace these differences in the subsequent history of the outer and inner layers respectively, under circumstances where it can be scarcely doubted that the mass was originally of the same composition throughout. On the evidence of cases of this kind, the law, (that is, the expression of general opinion,) that its future tendencies are immutably imprinted on the nascent product, is still admissible with the qualification, that these tendencies, when abnormal, are liable to be corrected by the neighbourhood of healthy tissues, or, that they are more rapidly and characteristically displayed in the parts furthest removed from such possibly corrective influences. I think, however, that we must not call such a qualification an inconsistency.

To recapitulate briefly, and in more general terms, what the above cases are intended to illustrate. The unusual products of inflammation of serous membranes, which we recognise and know where to expect in acute disease, may be met with in the pleura (taking our illustrations from this part) in a chronic form. The fibrinous products originally effused remain, under such circumstances, long undistinguishable from ordinary fibrinous exudations, save in their indisposition to undergo the ordinary changes. But their peculiar properties are not lost, for all that they may have lain hid so long. The interior softens at last into a matter closely resembling pus; and the walls, even though they may have undergone the changes of ordinary fibrin, sometimes display their origin in their tendency to earthy degeneration. (a) As to the immediate causes of the softening; though we may dismiss the idea of the direct local agency of inflammation, yet it must be observed, that the three cases, (I. III. V.) cited as examples of this secondary softening, died of acute disease, if not of actual inflammation.

The subject of encysted empyema is not merely pathologically interesting. Clinically as well as anatomically, the distinction between general and partial pleurisy is important. I would, therefore, briefly, in conclusion, survey it from this point of view.

There can be few things more gratifying to a patient than to be at once delivered of the load of fluid which had oppressed his breathing, by the very simple operation of tapping his chest. The pain and danger of the operation are small beyond all proportion to the amount of relief conferred. And the quantity of fluid drawn off furnishes an answer which all are willing to accept, as to the propriety of the operation, had there been any doubt before. One feels almost ashamed of credit obtained on such easy terms as by tapping a chest distended with fluid.

But the case is wholly altered, when we have to deal with circumscribed, or encysted empyema. The distress of the patient under such circumstances is at least as great as in the case of general pleural effusion. For, though he may not suffer so much from general oppression of his breathing, yet the difference is more than made up, I suspect, by that very painful sensation which arises from the tension of parts. With all this urgent demand for relief, and evident distress and danger, there is the most extreme difficulty in determining both the exact nature of the lesion, and, what is of the greatest importance towards its removal, its exact seat. And after all these difficulties, there comes no such evident confirmation, from the amount of the products of the operation, that it was required. The presence of three or four ounces of pus would scarcely seem enough to produce all the constitutional symptoms of empyema. And the evacuation of so small a quantity is, at first sight, scarcely a sufficient explanation of the immediate relief to these urgent symptoms,—the turning point of a man's life. But from particular observation of these cases, there can be no reasonable doubt of the correctness of this conclusion. Nor, on the more general grounds of analogy, of the comparison, namely, of these cases with those where pus is tightly confined in other parts of the body, have we any reason to reject it.

Now, clearly, the fluid matters, in any case where these symptoms depend upon tension, must be confined by tissues of considerable strength, and so, almost necessarily, of considerable age. Recent soft fibrin could not resist such pressure. Though the matter might, indeed, be confined in a cyst of this nature at first, yet the case would soon become one of general recrudescent pleurisy, in consequence of the new fluid matter being forced into the meshes of the older, but still soft tissue. We must refer the state of parts which

(a) I have no unequivocal cases at command in proof of this statement. It rests mainly upon Rokitansky's expressed opinion, that fibrinous exudations which undergo earthy degeneration have been originally, if solid, of the granular (*crümps*) form.—Path. Anat. Band. I. s. 270. Gendrin also observes, that earthy degeneration is most apt to occur in cases where the absorption of the fluid products, and the reparation of the other effects of inflammation has been tedious; in cases, judging from his description, very analogous to Rokitansky's *crüpos* class.—Hist. Anat. des Inflam. s. 250.

seems essential to the production of encysted pleurisy, in all the severity of its symptoms, to one of two pathological conditions. Either there must have been previous partial pleurisy, terminating in partial adhesion, and leaving the rest of the pleura untouched, and free to become the seat of a new attack of inflammation with effusion. Or else all the parts may have shared in the first attack of pleurisy, though this limited portion of the membrane, from whatever cause, have not become adherent. These appear to be the only two available explanations; for considering how very rare, not to say quite unknown an occurrence inflammation (a) of old tough connecting fibro-cellular tissue is, on general grounds, apart from the anatomical objections which examination of particular cases supplies, we may reject inflammation of a limited portion of such connecting tissue as a common cause of encysted empyema. In choosing between these two explanations, the fact of the contents of pleural cysts being usually puriform (b) favours the latter,—namely, that of an incomplete adhesion between the two opposite surfaces to such an extent. Expressed in general terms: this form of encysted empyema seems to belong rather to pleurisy, where the extent of repair, rather than the extent of inflammation, has been limited.

Speaking of encysted empyema generally, of the cases where the obliteration of the pleural cavity has not been complete, but a cyst filled with puriform fluid remains:— there are no grounds for supposing that formidable symptoms are more likely to ensue in those where the disease has originated in the mode above described, than where it has resulted from the more ordinary processes. For it may be necessary to mention, that the proper subject of this paper is not the ordinary process by which encysted empyema is formed. Happily, the uncertainty of these abstract pathological questions has no relation to the question of treatment, when, at some remote period, if so it should be, these patients come under observation; for the rule is the same in all cases of obscure chest disease following pleurisy,—however slight the symptoms of the original disease, however complete the recovery, and however long the interval, to examine most minutely the condition of the chest. We should look very anxiously after any signs of imperfect reparation, after anything which led us to suspect that the lung was not in close contact with the walls of the chest at any part, especially posteriorly, and in the lower part. And though very often such curious anxiety might be of little good to the patient, nor the information obtained available to direct any measures for his cure or even relief, yet, to solve one of these clinical problems now and then, so as to cure one patient who would otherwise have died, would be an ample reward for all the pains spent to no purpose on the rest.

If it were only that this subject is so obscure and so difficult, it would be very interesting as a pathological exercise, even though it were of no practical importance. But, in fact, encysted empyema constitutes a very anxious class of cases, (anxious for the very reason, that there may be so much to be done,) depending on our care, and accuracy, and decision. The doubts and difficulties which beset the diagnosis and treatment of pleural effusions are all concentrated here. Our pains in making out many cases will often give us only the sad assurance that they are hopelessly irremediable, and the less we do the better. But it is not always thus; all these cases are not to be left alone, after our pains spent in making them out. It is often, indeed, a very difficult task to discriminate those cases to which curative means are fairly applicable, and one requiring the highest skill and refinement in auscultation. But from these difficulties it is very satisfactory to turn to the recorded success of the results of surgical interference with cases of empyema, which, from the small amount evacuated, we may consider as encysted.

It would be idle to dwell on the treatment of this class of cases here. For the skill which should distinguish them during life could scarcely be divided from the knowledge of the general principles which should guide their treatment. And the particular indications of each case could not fail to display themselves in the searching examination on which alone their diagnosis could be founded.

(a) As distinguished from purulent infiltration by gravitation.

ON THE PROPAGATION OF YELLOW FEVER BY CONTAGION.

By A. BRYSON, M.D.,
Surgeon Royal Navy.

Unless a very large proportion of the members of the Medical profession be greatly in error, it appears to me that the following summary of facts would not be out of place as a pendant to the "Report on Yellow Fever," lately presented to the public by the Board of Health. Acting, no doubt, from purely disinterested motives, and with a view to the public good, the Board have collected an immense amount of evidence for the purpose of proving the non-contagious nature of that disease, and, consequently, the inutility of quarantine restrictions; but, entertaining apparently an undoubting belief in the soundness of their own preconceived opinions, they have not thought it necessary to bestow the same degree of labour and attention in collecting evidence opposed to the theory they have adopted; or else, having fully examined all the facts which tend to support the theory of infection, and having collected all the information they could from men practically acquainted with the subject, but holding opinions opposed to those adopted by the Board, they have come to the conclusion, that all the evidence which can be adduced in proof of its propagation by infection is unworthy the attention either of the Government or of the public.

The good or evil that may result from the distribution of the Report on the Yellow Fever remains to be proved; but, whether it be good or evil, the amount of responsibility incurred by the three members who have signed it is, or ought to be, a sufficient guarantee that they have so carefully examined every circumstance connected with the points at issue, as to enable them to deliver a conscientious opinion, and to retire from their task without the slightest dread of the consequences.

It is almost superfluous to quote the oft-repeated tale of the Bann, but it stands on record as the first, and perhaps the best proof that has yet been adduced of the propagation of the disease by a specific personal virus.

Her crew contracted fever at Sierra Leone, in March, 1823. On the 25th of that month she went to sea, where, far from the influences of the land, the disease continued to prevail considerably beyond the usual period of incubation. After a voyage of thirty days, she anchored, on the 25th of April, at the Island of Ascension. The sick were immediately landed, and placed in tents at a distance from the garrison, and quarantine restrictions were established, but were not enforced with sufficient care. In the course of three weeks after the arrival of the vessel, the disease broke out among the residents on the island, where it never had been known before to prevail.(a) In the course of a few months it entirely ceased, and did not again appear until re-introduced ten years afterwards under precisely similar circumstances.

In May, 1829, the Eden and Champion sailed from Sierra Leone, having yellow fever on board, and proceeding down along the coast, they arrived at Fernando Po,—the one on the 11th, and the other on the 14th of June. A number of cases of yellow fever were immediately afterwards landed, and, in the course of about three weeks, the disease made its appearance among the white residents in the settlement, and continued to prevail (being kept up by the arrival of susceptible Europeans) until the following year, when it entirely ceased.(b)

Although this is, perhaps, one of the most unhealthy islands in the world, still there is no proof, nor is there any reason to believe, that yellow fever had ever before shown itself there; and it most certainly has not re-appeared, since it ceased at the time above-mentioned.

In the same year the Sybille, which had been cruising in the Bights of Benin and Biaffra, came into the anchorage at Fernando Po, on the 21st of June. On the following day she received a number of men from the settlement, who had been left there by the Eden and Champion.(c) On the 26th of June the disease began to attack the crew of the Sybille, although it did not appear in any other vessel in the Bights, nor in any vessel lying in the adjacent anchorages of the island, or of the mainland.

(a) *Vide* Sir William Burnett's Account of the Fever in the Bann.
(b) *Vide* Epidemics of Sierra Leone.
(c) *Vide* Epidemics of Sierra Leone.

In May, 1836, yellow fever was contracted by the crew of the Curlew, at Sierra Leone; immediately after which she went to sea, and, on the 6th of June, she anchored off Bathurst, in the Gambia, with many of her crew ill of the disease. All the sick men were immediately landed, and, in a fortnight afterwards, the disease began to attack the white population in the settlement, the first person attacked being the surgeon who attended the men from the Curlew; and the second, his servant. The disease prevailed for a few months, and then ceased.(a) There is no record that it had ever before made its appearance in the Gambia, and most certainly it has not appeared there since.

While the fever raged at Bathurst, several merchants left the colony in a small vessel on the 9th of August, and proceeded to Goree, a small island about 100 miles to the northward of the Gambia. On the passage one of them was attacked with the fever; and on the 12th, the day of their arrival, he was landed at Goree, where he died. His mother, who had attended him, was attacked on the day of his death, and also died. Several other gentlemen arrived by another vessel on the 17th, from the Gambia, one of whom was attacked on the 19th, and died with black vomit on the 21st. About three or four weeks after these events, the disease broke out at Goree, and carried off a vast number of the population.(b)

"Goree has been colonised by Europeans upwards of ninety years, but it does not appear, either from written record or from oral tradition, that it was ever visited by yellow fever before this epidemic broke out, and most certainly it has not been so afflicted by that disease since."(c)

In December, 1837, the crew of the Ætna contracted yellow fever at Sierra Leone, and afterwards sailed for the island of Ascension. The disease, far out on the ocean, continued to attack the crew long after the expiration of the usual period of incubation,—namely, upwards of forty days. She arrived at the island of Ascension on the 20th of January, 1838. The fever cases were landed on the island, and placed in quarantine. Several other vessels arrived from the coast with the disease on board, or with patients recovering from it; the last on the 23rd of March. In less than a fortnight from the latter date, the disease again broke out among the residents, and after raging with great fatality for two or three months, it began to decline, and finally ceased. Not a single case of the disease had been observed on the island since 1823, when it was introduced by the Bann, and up to the present period it has not reappeared since its cessation in 1838, when introduced by the vessels arriving from Sierra Leone with the disease on board.(d)

The crew of the Eclair were attacked with yellow fever at or near Sierra Leone in 1845. Whether the disease in this instance originated within the vessel, or was introduced from the land, is immaterial as regards the questions of contagion and quarantine. She ran off the coast, touching, in her course, at the Gambia and Goree, and anchored in an English harbour at the island of Boa Vista. All the fever cases were landed on a little island in the bay or harbour; and the remainder of the crew were quartered in the town. In the course of at most two or three weeks, the disease began to attack a guard of soldiers who were employed at the fort in which the sick were lodged, and subsequently it appeared in the town; the first person attacked being a woman who lived in the house next to that in which were located two of the surviving soldiers of the guard when ill, with whom she had had frequent communication. The disease then began to extend, and rapidly spread all over the town, and subsequently, not to all, but to some of the adjacent villages.(e)

Now, it is not within the memory of man, nor is it on record, that yellow fever ever before made its appearance on this island, or, indeed, on any other island of the group; and since the epidemic which followed the arrival of the Eclair disappeared, no cases, so far as can be ascertained, have occurred either in Boa Vista or in any of the other islands.

Whether or not the eruption of yellow fever in these several instances was merely an accidental occurrence following its introduction among a previously healthy population, I will leave others to judge; but, notwithstanding the conclusions come to by the Board of Health, under similar circumstances, in future, I would have no hesitation in recommending the adoption of quarantine restrictions,—but quarantine restrictions differing materially from those which are practised in the present day.

GENERAL CORRESPONDENCE.

THE UTERINE SOUND.

[To the Editor of the Medical Times and Gazette.]

SIR,—I had intended that my controversy with "M.D. Londin," so far, at least, as I was concerned, should end with my last letter; but I consider it due to myself to explain one passage in that letter, which he has pointed out, and which, taken as he construes it, certainly bears anything but the sense I hoped and wished to convey. I cannot help thinking that the meaning of it might be easily seen through by one really anxious to discover it, still, on re-perusing it, I must acknowledge that "M.D." is quite correct in his remarks on it. I will not, in explanation, plead a mere "typographical error here," for if I did so I should be guilty of a falsehood. The obscurity of the passage resulted from my writing in the midst of numerous occupations, and with a foregone impression on my mind.

The passage referred to is the following:—"If the escape of a brownish, bloody-coloured fluid, from a dilated os and cervix uteri, be not an indication of a canal (whether quite pervious or not) preternaturally and relatively too small for its purposes, I ask what it is an indication of? If this discharge be not evidence of retained menstrual fluid, what is it?" I fully allow that the above sentence is very badly constructed; it does not carry the meaning intended by me, but it occurred as follows:—

In the *Medical Times* for December 6, Dr. Rigby gave the clinical report of a case, which he diagnosed by the sound to be one of obstructed dysmenorrhœa, and which he successfully treated by employing mechanical dilatation of the contracted uterine canal, with the escape of some "brownish, bloody-coloured fluid," etc.: "M.D. Londin.," on the other hand, objected, "that this model case of mechanical dysmenorrhœa from obstruction was, from Dr. Rigby's own showing, not a case of obstruction; that the diagnosis was erroneous, and that the treatment employment was uncalled for, and consequently improper;" that it was, in short, merely an instance of those obstetric "abominations" which have done so much violence to "M.D's" moral sense, and which he feels it to be his vocation to expose and put down; for no evidence, according to him, had been given by Dr. Rigby to show that the escaped fluid was catamenial. Now, believing that the circumstances of the case, as detailed by Dr. Rigby, presented the precise kind of evidence required in proof of his accuracy, I penned the sentence under consideration, referring, as any unbiassed person must see, to the case in its entirety, as related by Dr. Rigby, and commented on by "M.D." "If," I said, "the escape of some brownish, bloody-coloured fluid from a dilated os and cervix uteri," etc. I confess, however, that it should have been, "from an os and cervix uteri, which were found contracted, and which had been dilated by mechanical means," etc.; and then, perhaps, even "M.D." would have comprehended its meaning.

Of the reddish discoloration of the sound, or the occasional escape of a little blood after its use, I am quite as well aware as "M.D.;" but he knows, if he knows anything about the matter, that this is a very different affair from that related by Dr. Rigby.

To "M. D.'s" other objections and statements I do not think it worth while to reply; for I feel that it would only tend to prolong a useless discussion, in which "M. D." and I are not contending on equal terms. Moreover, "M. D." has conceded the chief point in dispute, viz., that the uterine sound is applicable to some cases. This is just what I claim for it; here, then, we agree; but, unfortunately, not so as to the size of the instrument, or the precise kind of cases in which it may be employed. I deem it valuable in certain uterine ailments and conditions where "M. D." is at issue with me, and on his part quotes its employment in the differential diagnosis of "pendulous tumours of the uterus" and "pregnancy;" in which description of cases I confess my total and wilful ignorance of its use.

"M. D. Londin" has been good enough to tender me a piece of advice. As I am now taking my leave of him, I should like to reciprocate his kindness; and therefore I will venture to recommend him, for his own sake, to explain, without

any more hesitation, what it was he meant to convey by describing the bulb of the uterine sound as varying "from a quarter to half an inch in diameter;" a task which he has not yet accomplished. If he cannot, as I fear, do this, I entreat him to say so at once candidly; and when next he feels impelled to set about correcting anonymously the supposed improprieties of his professional brethren, or impugning their motives, not to draw so largely upon his imagination,—a faculty which has led some people, as he knows, into all sorts of strange conceits, even to the singular anatomical attempt of manufacturing nerves out of cellular tissue.

I am, &c.

Birkenhead, Cheshire. CHARLES HAYES HIGGINS.

SKODA'S THEORY OF CONSONANCE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I quite agree with Dr. Drysdale, that Dr. Walshe has, in some degree, misinterpreted Skoda's theory of the cause of the increased thoracic voice; and, if I am not mistaken, there really is no great difference between Skoda's theory, and his manner of interpreting it, and that proposed by Dr. Walshe. Both these observers reject Laennec's account of bronchophony.

Dr. Walshe suggests that it may be caused by an echo arising from intensification of sound, by reflections brought to a focus within the bronchi. (Walshe, Treatise, p. 129.) He then goes on to say, that the conditions of reflection are fulfilled in a hepatized lung, the tubes being now surrounded by semi-solid material proper to reflect and concentrate sound. They resemble so many speaking trumpets, in which the augmentation of sound is produced by reflection from their quivering walls. By this reflection, vibrations, otherwise divergent, are propagated in the same direction, and intensification of sound is produced. "Skoda's," he says, "exclusion of the tracheal and bronchial walls from all participation in the phenomenon (he is speaking of the increased thoracic voice), is at variance both with theory and experiment."—P. 129.

Now, what says Skoda? The force "of the consonance depends upon the form, etc., of the enclosed space, and upon the nature of its walls; the more completely the sound is reflected by the walls, the stronger is the consonance.(a) The cause of the increase of sound in a speaking-trumpet is well known. The air contained in the trachea and bronchial tubes consonates with the voice, in so far as the walls confining it have, in respect of their power of reflecting sound, a similar or analogous condition to the walls of the larynx, of the mouth, and the nose." He then tells us, that the consonance of the voice is very feeble in the finer bronchi; for these are merely membranous tubes, ill-fitted to reflect sound; if the consonance be increased in these, either their walls must have become cartilaginous, or the tissue around them must have become condensed.—P. 40. All those diseases which render the parenchyma of the lungs firm, dense, and solid, increase its power of reflecting sound, and the force of the consonance, and the reflection of the sound, are greater or less according to the density of the parenchyma.—P. 41.

Now, surely, there is little difference here between the conditions laid down by Skoda as absolutely necessary for the increased thoracic voice, and those laid down by Dr. Walshe. How Dr. Walshe can make Skoda reject the tracheal and bronchial walls from all participation in the phenomenon, I am at a loss to understand; as Skoda describes in such particular manner the necessity of the bronchial tubes being rendered good reflectors of sound in order to produce the phenomenon.

Perhaps, in justice to Skoda, you will be kind enough to insert the above. I am, &c. W. O MARKHAM,

Assistant-Physician to St. Mary's Hospital.

Clarges-street.

SUPERINTENDENTS OF COUNTY LUNATIC ASYLUMS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The observations of "Justitia" in your number of the 12th of June deserve the attention of those members of the Profession who seek appointments in public lunatic asylums.

It will be found, upon inquiry, in asylums where a seat at the Board of Directors has been conceded to the superintendent, with absolute power in the hiring and dismissal of servants, etc., that great mischief has ensued. Several years since an asylum was established in this county by voluntary contribution: at the opening of the Institution, great power was given to the superintendent, and a seat at the Board of Directors.

(a) Skoda's Treatise, p. 39. Fourth edition.

The physicians residing in the town declined the appointment of "visiting physicians;" and wisely, for they would have had no power to enforce their directions.

The superintendent having run to the length of his string with the Directors, and receiving a check, resigned. After he had left the asylum, a large bill was sent in by a respectable legal firm in the town, for fees and charges in defending actions commenced by servants of the establishment against the superintendent for wages; and these proceedings were unknown to the Committee.

In all public medical charities the stipendiary officers should be represented by the honorary office-bearers; while a man is a stipendiary he is a subordinate, and, if left without supervision and control, may permit serious mischief to be done. Your Correspondent has referred to Hanwell. When Sir W. Ellice resigned, (all respect to his memory,) it was said that he did so in disgust from his power being diminished.

Has the present distinguished head of that asylum been less successful under a new order of things?

I am, &c. A COUNTRY SURGEON.

[To the Editor of the Medical Times and Gazette.]

SIR,—When an objector stumbles upon and makes known your strongest reason for an opinion you have stated without giving that reason, you should not, on account of the motive, be ungrateful for the fact,—that he seizes the sharp edge of the argument, and presents you with the handle.

On this principle, have the goodness to convey my thanks to "Justitia," who will, I hope, excuse the liberty I shall take in re-stating his argument somewhat more plainly.

He thinks that the superintendent of a lunatic asylum should not be present at the meetings of the visiters, because it would be disagreeable to the feelings of the other officers; who, it is supposed, would be prevented by his presence from making their appeals to the Board.

If this means anything, it means that, in "Justitia's" opinion, the normal condition of asylum officers is one of misunderstanding and quarreling; and that, under such conditions, for the sake of fair play, all the parties should be excluded from the Court of Appeal. I object to the premises, and affirm, with little fear of contradiction, that, except in one or two well-known instances, the officers of asylums work together with remarkable unanimity and concord; and that the presence of the superintendents at the Board-meetings is far more frequently advantageous to their brother officers and their subordinates than it is to themselves. The exceptions occur in those asylums where the visiters have a *penchant* for clever, report-writing matrons, or for managing the superintendent's business themselves, by means of snug little sub-committees, which the most influential county men find it impossible to attend.

The strongest reason for giving sufficient power to the superintendent is, that under such an arrangement, patients, servants, and officers are more comfortable and contented, than when the affairs of the establishment are managed by peddling sub-committees, which act as ready courts of appeal to all the little quarrels of the inmates.

"Justitia" has strung together a list of appellations, synonymous and otherwise, and asserts, that a superintendent should not be all these. I never heard of any one proposing that he should be, and entirely agree on this point, although I do not agree with the manner in which the very narrow position taken up in my letter has been amplified until it is scarcely to be recognised. Of this I must complain, and say, *Fie at Justitia!* I am, &c.

A COUNTY SUPERINTENDENT.

MATICO IN UTERINE HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—The late discussion in the Medical and Chirurgical Society has recalled to my recollection a correspondence carried on in the *Medical Times* during the last autumn on the subject of uterine hæmorrhage.

I did not observe in the notices of the treatment, that the use of matico as an effective remedy was adverted to, of which agent, if it were in common use, some mention would probably have been made.

I wish to draw the attention of the Profession to it, believing that its use will in many cases prove of essential service. For more than three years I have been in the habit of occasionally using the infusion as an injection into the uterus in cases of hæmorrhage, and have generally found it succeed in diminishing, and finally arresting the discharge. In applying it, the end of the pipe of the

syringe was introduced into the uterus, and a quantity of the infusion, at a temperature of 50° to 55°, injected, sufficient to irrigate the cavity. The infusion of matico used in this way appears to be peculiarly adapted to arrest the bleeding so often consequent on retention of decidua after abortion in the early months. It is applicable even in *post-partum* hæmorrhage, mixed with an equal quantity of infusion of ergot, to which, if a general stimulant is necessary, proof spirit may be added. It is also useful in menorrhagia and other uterine discharges.

If the publication of this note will lead accoucheurs to test the power of this styptic in such cases its purpose will be fully effected.

I am, &c. M.

MEDICAL NEWS.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 18th inst. :—

Barker, Alfred James, Paramatta, Australia.
Dansey, George Frederick, Blandford, Dorset.
Gwynne, Daniel, Brighton.
Leonard, Frederick Lewis, Royal Navy.
Lewis, Charles, Killarney.
Marsland, Robert, Manchester.
Palmer, Charles, Kirton-in-Lindsay, Lincolnshire.
Skipton, Samuel Stacy, London.
Tourrette, Charles, Mauritius.
Wigglesworth, Thomas, Coleford, Gloucestershire.

New Councillors.—From an official advertisement in the *London Gazette*, it appears that the following gentlemen have given the necessary notice of their intention to present themselves for election into the Council of the Royal College of Surgeons:—Messrs. Bransby Blake Cooper and William Coulson for re-election, and Mr. George Gulliver, of St. Mark's-crescent, Regent's-park, nominated by Messrs. Judd, Lloyd, Phillips, Paget, M'Whinnie, and Mantell; Mr. Richard Partridge, of New-street, Spring-gardens, nominated by Messrs. Norman, Fergusson, Bowman, Shaw, Wilson, and Paget; Mr. Thomas Tatum, of George-street, Hanover-square, nominated by Messrs. Cutler, Shaw, Hewett, Pollock, Johnson, and Morgan; and Mr. Alexander Shaw, of Henrietta-street, Cavendish-square, nominated by Messrs. Stone, Paget, De Morgan, Tatum, Bowman, and Moore.

Apothecaries' Hall.—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 17, 1852:—

Dix, Arthur, Beech-street, Barbican.
Puckle, George, Camberwell.
Salter, John Reynolds, Exeter.
Timothy, Peter Vincent, Redcross-street, Barbican.

Medical Honours.—We have great pleasure in announcing, that, at a Convocation held in the University of Oxford, on Wednesday last, Dr. W. P. Alison, Professor of Medicine in the University of Edinburgh, and one of Physicians in Ordinary to Her Majesty in Scotland, and Richard Owen, Esq., F.R.S., and Hunterian Professor and Conservator of the Museum of the Royal College of Surgeons, had the honorary degree of Doctor in Civil Law conferred on them.

The Memorial of the Extra-urbem Licentiates, and the New Charter of the College of Physicians.—The following letter has been received by Dr. Laycock from Dr. Hawkins, in acknowledgment of the memorial of the Associated Extra-urbem Licentiates:—

"College of Physicians, London, June 22, 1852.

"Sir,—I beg to inform you that your memorial, addressed to the President of the Royal College of Physicians, has been laid before a Committee of the College, and has been received by them with the attention due to it. I am directed, however, to state, that no further measures can be taken at present towards obtaining a new Charter for the College, on account of the impossibility of procuring an Act from the present Parliament. And I am to assure you, that, before any settlement is come to between the College and the Government, the arguments contained in your memorial shall receive the fullest consideration.

"I am, Sir, your obedient servant,

"Francis Hawkins, M.D., Registrar.

"To Dr. Laycock, etc., etc., etc."

University of Oxford.—At the Convocation, held on the 17th inst., it was proposed to grant to the Regius Professor of Medicine and Anatomy 100*l.* out of the University chest, to be expended partly in setting up a portion of the zoological collection lately presented to the University by the Rev. F. Hope, and partly in the purchase of other anatomical preparations for the illustration of a course of lectures.

Mr. Roundell Palmer, M.A. and Q.C., has been appointed Deputy High Steward of the University of Oxford, in the room of the Hon. J. Chetwynd Talbot, M.A. and Q.C.

Obituary.—We regret to announce the death of Mrs. Bradbury, well-known as the proprietress of a Lunatic Asylum at Earl's-court.

Naval Appointments. — Surgeon Thomas Nelson, M.D. (1849), serving in the Cygnet sloop on the West Coast of Africa station, is appointed to the Penelope, flag-ship, on that station; Surgeon H. H. Turnbull to the Vestal; Assistant-Surgeons Culhane to the Vulcan; Henry Loney to the Vestal.

Addenbrooke's Hospital, Cambridge.—Mr. Edmund Carver has been elected to the office of House-apothecary at the above Institution.

Staffordshire General Infirmary.—Mr. William Webb, of Queen's College, Birmingham, has been elected House-surgeon and Secretary to the above Institution.

Middlesex Hospital School of Medicine.—The distribution of prizes at this Institution took place on Thursday, June 17, 1852, the Right Hon. the Earl of Carlisle in the chair. There were present—Lord Bayning, the Countess of Airlie, Sir R. H. Inglis, Bart., M.P., Sir Robert Ainslie, Bart., Sir Walter Stirling, Bart., General Cabrera, Comte de Moulla; Sir Charles Lyell, F.R.S., the Hon. Admiral W. H. Percy, the Hon. T. W. Percy, the Hon. Misses Waldegrave, the Rev. Temple Frere, Charles Babbage, F.R.S., T. M. Arnott, F.R.S.; William Tooke, F.R.S., William Hawes, Esq., Michael Smith, Esq., Walpole Eyre, Esq., John Pepys, Esq., Thomas Hunt, Esq., etc. etc. The awards were as follow:—Medicine (Dr. Crawford and Dr. Thompson.)—Prize: Mr. Thomas Dixon, Bedford; certificate: Mr. Henry James Ellery, Truro. Surgery (Mr. Shaw).—Prize: Mr. Henry James Ellery, Truro; certificate: Mr. Edward Vernon, London. Physiology (Mr. De Morgan).—Prize: Mr. William Lucy, London; certificates: Mr. Edwin Stephens Collins, Sherborne; Mr. Henry Cooper Rose, Canterbury — equal; Mr. Robert Hall Bakewell, Waltham Abbey. Anatomy (Mr. Moore).—Prize: Mr. Edward Vernon, London; certificate. Mr. George Spicer, Tonbridge Wells. Demonstration (Mr. Nunn).—Prize: Mr. Henry James Ellery, Truro; certificates: Mr. Edward Vernon, London, and Mr. Charles Hemming, Kimbolton. Chemistry (Mr. Taylor and Mr. Heisch).—Prize: Mr. Robert Hall Bakewell, Waltham Abbey; certificate: Mr. Chambre R. C. Vigurs, Truro. Midwifery (Dr. Frere).—Prize: Mr. Thomas Dixon, Bedford; certificates: Mr. Daniel Balding, Barkway, Mr. James C. Copland, London. Materia Medica (Dr. A. P. Stewart).—Prize: Mr. Edward Vernon, London; certificate: Mr. William Lucy, London. Forensic Medicine (Dr. Goodfellow).—Prize: Mr. William Henry Rean, Plymouth, and Mr. Henry James Ellery, Truro—equal; certificate: Mr. William Saville, Wakefield. Botany (Mr. Bentley).—Prize: Mr. Edwin Stephens Collins, Sherborne; certificate: Mr. Edward Vernon, London. Prize in Clinical Medicine.—Mr. Henry James Ellery, Truro. Prize in Pathology (presented by Alexander Henry, Esq., M.P.)—Mr. Robert John Dempster, Brighton. Prize presented by the Treasurers of the Hospital.—Mr. Henry James Ellery, Truro. General Certificates.—Messrs. Josiah Austen, Robert Hall Bakewell, Daniel Balding, James C. Copland, Robert John Dempster, Edward Rawson Denton, Thomas Dixon, Henry James Ellery, Robert Ellery, Nathaniel James Grant, James Hadaway, Charles Hemming, William Lucy, Henry Frederick Marley, Humphrey, Leverington, Maysmore, David Mathias, Henry C. Rose, William Saville, George Spicer, Edward Vernon, Chambre R. C. Vigurs, Lake Young.

The British Association for the Advancement of Science.—It has been arranged, that the meeting of this Association is to commence on the 1st of September, at Belfast, all the different sections assembling under one roof, in the new Queen's College, which, as well as all the public buildings in the town likely to be useful in this great gathering of science, has been placed at the disposal of the Managing Committee. It is said that the influential inhabitants of Belfast are making great preparations for the accommodation and comfort of their visiters.

Surgeon Minter.—The Governor-General of India, in a Council notification, alludes in flattering terms to the services of Surgeon Minter, whose personal exertions, he says, have been commended to him. General Godwin speaks highly of the attention and humanity of Superintending Surgeon Montgomery. Our

military and naval brethren, by and by, may anticipate full justice being done them.

THE MANCHESTER CHARITIES.—The theatrical performances at Manchester, on behalf of the local charities, have realised the sum of 850*l.*, including 100*l.* in donations,—a handsome amount to be derived from such a source.

THE *Constitutionnel*, French newspaper, states, that the Austrian Government has given in its adhesion to the convention proposed by the Sanitary Commission, for reforming the quarantine laws; and it is inferred that the Italian States will follow the example of that Government.

BY letters from Queenstown we learn, that the hospital at Haulbowline is undergoing a complete repair, and we have no doubt that ultimately it will be worthy the first naval port in Ireland.

HEMEL HEMPSTEAD.—The election of a coroner for this district took place on the 7th and 8th of June. The candidates were Mr. Pope, surgeon, and Mr. Day, solicitor. On the day of nomination, the advantages to be gained by electing a medical rather than a legal coroner, were most ably shown by Mr. Pope. By two o'clock on the 8th, that gentleman had a large majority, the voters up to that time being the freeholders of the district. Towards the close of the poll, however, the scale was turned in favour of Mr. Day, by the votes of 130 ticket-holders, having an interest in Boxmoor. The validity of the votes given by these persons has been called in question. This much is certain, by their votes the freeholders of the district have lost the services of one who would have proved a most valuable coroner.

DISEASE IN VEGETABLES.—We learn that a disease, similar in its effects to the potato-blight, has made its appearance among the bean-crops of the kingdom; and is even more rapid and virulent in its destructive effects.

DEATHS *in the Metropolis for the week ending Saturday, June* 19, 1852.

TO CORRESPONDENTS.

In consequence of the copious Index which we publish this week, and our desire to include in our present Volume some of the papers contained in this Number of our Journal, our customary "Leading Articles" are omitted. The great value of the Index to those referring to the "Medical Times and Gazette" renders any apology unnecessary. The following Articles are in type:—Notes on some of the more unusual Terminations of Scarlet Fever. By ALEXANDER WOOD, M.D.—Report of a Case of Farcinomatous Inflammation of the Left Foot successfully Treated with the Sesquicarbonate of Ammonia in Frequent and Concentrated Doses. By F. W. MACKENZIE, M.D.—On the Blood-vessels and Trabeculæ of the Spleen *(Illustrated.)* By W. OLIVER CHALK, Esq.—A Sketch of the Medical History of the 47th Regiment. By GEO. SAUNDERS, Esq.—Case of Wound of the Femoral Artery with a Chisel, with Ligature of the Vessel. By R. MASON, Esq.—Illustrations of Clinical Medicine and Pathology. By Drs. BURROWS and KIRKES.—On the Precipitation of Albumen by Acids and Neutral Salts. By E. A. PARKES, M.D.—Correspondence on Professional Etiquette between Mr. Close and Dr. Aikenhead.—On Homœopathy.—On the Treatment of Measles, etc., etc. We would gladly have inserted several of these Communications, but for the reason alluded to above.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you allow me a space in your Journal to make a few remarks on the probable effect the gold mania will have on the medical profession; and, having been out in the colonies in charge of emigrants under the Government plan, to offer a few words of advice to such of my medical brethren who think of trying their fortune at the diggings. When we consider the number of ships that will leave weekly our ports for the next two or three years, and each carrying qualified surgeons, it must be very evident, that it will clear off a vast number from our over-stocked body, and will do much good to those who remain, especially to that ill-paid class of men, qualified assistants; and, by the advertisements which are weekly taking place, they are already becoming scarce. And let me ask, who would remain an assistant when he can make his £100 a-week by digging gold (?) However, knowing what it is to be an assistant, I think the time has arrived when they have a right to demand what is right for their labour, and I think that no one holding a single diploma should accept a situation under £50 per annum, and, with the double qualification, £70 or £80. It is all very well for practitioners to say, they can't afford it, but I know better, and there is this alternative only. Unless they pay this sum, the assistants will be either taking out emigrants, or flocking to the diggings. A few words, now, to those who think of going out in some of these emigrant ships,—those who consider it a sinecure will be very much mistaken; and I do hope, that none will be found who will do themselves and their fellow-surgeons the injustice to give their services for merely a passage, when they have the power in their own hands of being properly and fairly remunerated. I would, therefore, recommend, that none go out for less than £100 for the voyage, or 10s. per head for each emigrant. This is, I consider a fair remuneration, and what, from the present increase of the rate of freights, can be fairly paid. Most probably, nearly all the surgeons who are going out will remain in the country, and will, no doubt, from the increase of population, find employment and plenty. Knowing as I do, from experience, the state of the country, it seems as if Providence had especially ordained the colonies as a resource for our superfluous population, many of whom, not merely among the lower classes here, are barely getting a living. There they will find plenty of all the necessaries of life for a moderate exertion. I am not an advocate for monopoly or combination; but it is notorious, that hitherto no class of men have been so ill paid as qualified men as assistants, or giving their services to merchant-ships. The time has now arrived when they have it in their power to demand a fair and just return for their outlay, and those who fail to take advantage of it, deserve to be treated with that contempt which is the sure consequence of all who hold their services too cheap. I am, &c.

M.R.C.S. and L.S.A.
AND LATE SURGEON-SUPERINTENDENT OF EMIGRANTS.

Mr. Lowe, of Congleton.—The paper will appear without delay, and we shall be glad to receive more communications.

Mr. Spence Bate's papers will be continued.

Philo-Chirurgus.—We have referred the question to a competent authority.

Maidstone.—Sumbul has been strongly recommended as a remedial agent in the treatment of epilepsy, and some cases that have been brought under our own notice speak in its favour. We believe Messrs. Savory are the great importers of the new drug. It is said to be a nervine tonic.

COMMUNICATIONS have been received from—

Dr. ROE, of Plymouth; A SURGEON; Mr. POCOCK, of Brixton; Mr. SPENCE BATE, of Swansea; A HATER OF ALL SORTS OF QUACKERY; Mr. LOWE, of Congleton; Dr. LOCKHART ROBERTSON, of Cambridge; Mr. BEALE, of the Harrow-road; Mr. STARTIN, of Savile-row; X. Y. Z.; Dr. MARKHAM, of St. Mary's Hospital and Clarges-street; A COUNTY SUPERINTENDENT; Mr. LUDLOW, of Paternoster-row; Professor QUAIN, of University College and Cavendish-square; Dr. TAYLOR, of Guildford-street; Mr. BOON HAYES, of Sydenham College, Birmingham; A FOUR YEARS' SUBSCRIBER; Mr. GEORGE, of Hornton-villa, Kensington; Mr. DANIELL, of Newport Pagnell; Dr. KING CHAMBERS of St. Mary's Hospital and Hill-street.

HOSPITAL REPORTS—
Devon and Exeter Hospital:—
Deligation of the external iliac, 393
General Hospital, Bristol:—
Ruptured urethra, 415
Guy's Hospital:—
Abscess of the liver consecutive to dysentery, 15
Fibrous tumour of the labium; enucleation; recovery, 243
Large polypus of the uterus removed by ligature; recovery, 243
Hospital la Charite:—
Croup in an adult female, with expectoration of pseudo-membranous tubular moulds of the trachea; death; autopsy, 263
Profuse blood-letting in acute articular rheumatism, 416
Hotel Dieu:—
Successful treatment of chronic abscess with iodine injections, 320
Kent Ophthalmic Hospital:—
Melanosis of the left eye; extirpation of the globe, 620
King's College Hospital:—
Disease of larynx, rendering the operation of tracheotomy necessary, 65
Fungoid tumour of the chest, 215
Disease of hip-joint, 261
Case of elephantiasis Græcorum, with analysis of the urine, 291
London Hospital:—
The double flap operation, 86
Enlarged bursa over the right and left patella, removed by excision—enlarged bursa connected with the tendon of the semitendinosus; puncture; suppuration of the sac; cure—bursa over the internal malleolus of the right foot; failure of puncture; excision, 319
Extensive necrosis of the right femur; excision of part of the substitute bone; removal of a large sequestrum; recovery, 547
Necrosis of the tibia after fever; excision of substitute bone; removal of the sequestrum at three different periods; recovery, 548
Middlesex Hospital—
Tetanus, 108
Dislocation of the sternal end of the clavicle backwards, 415
Newcastle-on-Tyne Infirmary:—
Cases of aneurism treated by pressure, 566
Royal Berkshire Hospital:—
Stone in the bladder; absence of some of the ordinary symptoms; operation, 17
Strangulated femoral hernia; grangrene of the contained omentum; operation; death; post-mortem examination, 262
St. Bartholomew's Hospital:—
Dislocation of the cervical vertebræ; death; post-mortem examination, 188
The late death from chloroform, 318
On injuries of the arterial system; compound comminuted fracture of the left superior maxillary and malar bones, followed by profuse arterial hæmorrhage from the pterygo-maxillary fossa; small penetrating wound of the forearm piercing the ulnar artery and causing effusion of blood, 563
Penetrating wound of the forearm; puncture of the ulnar artery; punctured wound of the right forearm followed, after the lapse of a week, by profuse arterial hæmorrhage; deligation of the anterior interrosseous artery, 564

Cancer; second relapse; third operation, 618
St. George's Hospital:—
Albuminuria and its treatment, 38
Anæmia, its causes and consequences, 131
Secondary deposits, 565
St. Mary's Hospital:—
Double hare-lip, with fissure of the jaw, 188
Lithotomy, 466
Compound comminuted fracture of the left-arm; amputation at the shoulder-joint; prostration; death in eighteen hours, 619
St. Thomas's Hospital:—
Empyema from injury; death; post-mortem examination, 260
Hernia; sloughing of the intestine; cure, 393
Disease of the larynx; tracheotomy; necrosis of the cricoid cartilage, and abscess between the larynx and œsophagus opening into the œsophagus, 521
York County Hospital:—
Leucocythemia; liver and spleen hypertrophied; aneurismal cavity in the substance of the ventricular septum of the heart; suddenly fatal from rupture into the right auricle, 369
Hospital, Royal Berkshire, 17, 262

Ashmolean Society:—
Liebig's method of determining the amount of urea in urine, 226

Chemical Society:—
On a new method of estimating the quantity of the urea in urine, 97
Hippuric acid; populine, 176
Variation of potash and soda in certain samples of barley; compounds of cotton with the alkalies, 278
Contributions towards the history of tannic acid; on the detection and qualitative separation of tin, antimony, and arsenic, 603

Entomological Society:—
Remarks on the psychidæ, 175

Epidemiological Society:—
Appointments of foreign and colonial secretaries, 477
On the introduction into and progress of vaccination in Bengal, 630

Ethnological Society:—
On the Ethnography of Akkrah and Adampe, West Africa, 227

Liverpool Medical Society:—
Malignant disease of the uterus; uterus and appendages during a menstrual period, 98
Case of tubercular disease; cavities in lung showing a healing tendency, 148
Some observations on subcutaneous cysts, and the best mode of removing them, 201

Liverpool Medical and Pathological Society:—
Three cases of asphyxia from the inhalation of impure air; case of retention of menses from imperforate hymen, 353

Medical Society of London:—
External division of stricture of the urethra, 22
Galvanic battery and belt; calcification of fibrous tumour of the uterus; on the endosmotic action of medicines, 23
Encephaloid disease of the kidney; M. Junod's exhausting or hæmospasic apparatus, 50
On placing medicines on the tongue; ulcer of the stomach; extensive wound of the throat; death—on excision of joints, 73.
Fibrinous concretion in the aorta; fatty degeneration of the heart; the liver and its secretions; the arcus senilis and fatty degeneration of the heart; clinical illustrations of sub-acute ovaritis, with remarks on the diagnosis of that disease, 121
Portraits of Fothergill and Lettsom; yellow fever in Rio de Janeiro: on injuries to the spine, and their relation to the urinary organs, etc., 147
Discoloration of the hair after ringworm of the scalp; twist and adhesion of the umbilical cord; peculiar influence of mercury at the present time; the utility of copious bloodletting in cases of congestion and inflammation, 173
Five calculi removed by lithotomy, each containing a field bean for its nucleus; the coexistence of variola and vaccinia in an infant six months old; coiling of the cord; ossification of the retina, lens, and cornea; on topical medication in the treatment of diseases of the pharyngo-laryngeal membrane, 198
Dr. Ogier Ward's single-tubed feeding bottle; case of epispadias; nævi materni; their structure, peculiarities, and treatment, 224
Coincidence of vaccinia and variola; *serres-fines* in superficial rupture of the perinæum; genital malformation; foreign body in the larynx; the cause and prevention of death from chloroform, 252
On idiocy: its causes and treatment, 303
On the morbid conditions of the kidney giving rise to albuminuria, 351
A peculiar symptom of rheumatic ophthalmia; preservation of pathological specimens; on fatty degeneration, 428
Diseases of heart; general enlargement; old pericardical adhesions; dilatation of all the cardiac cavities and vessels; fibrinous deposits; perforating ulcer in the stomach, 476
Operations for ovarian dropsy; ligature of the external iliac artery; perforation of the stomach; on the nature and treatment of epilepsy, 530
Apparatus for the reduction of dislocations, 553
Case of gangrene of the lung; a new mode of applying topical medication to the larynx; what is metastasis? 578
Small-pox after vaccination; bony tumour of the uterus; ulceration of the appendix vermiformis, and obstruction of the bowels; on spinal curvature or scoliosis; on a new mode of operating for ovarian dropsy, 629

Newcastle Pathological Society:—
Case of popliteal aneurism cured by compression; cancer of the stomach encroaching on the lower portion of the œsophagus; Bright's disease; case of femoral hernia, 352

Paris Academy of Sciences:—
Comparative statistics of deaths from cholera in France in 1832 and 1849; researches on the presence of iodine in nature, and its effect on the goitre; on the employment of chloroform; on the employment of sulphate of zinc as an antiseptic, 124
On neuralgic amaurosis, 278
On the influence of the grand sympathetic nervous system on animal heat, 506
On the relative proportions of nutriment in various kinds of animal food, 553

Pathological Society of London:—
Cancer of the lungs, pleura, pericardium, bronchial, and other glands, 21
Specimens of the guinea worm; dysentery with extensive sloughing and ulceration of the large intestines, 22
Fatty degeneration of the heart, causing death by rupture, 48
A portion of the rectum which, having protruded, had been cut off; Anniversary Meeting, 49
Dr. Bence Jones's case of serous cysts of the kidneys; malformation of the aortic semilunar valves; rupture of the heart, consequent on fatty degeneration, and associated with softening of the brain; aneurism of the aorta; with a description of the morbid anatomy of the recurrent nerve compressed by it, 95
Crimson or hæmatoid crystals (of Virchow), and calcification of the minute arteries of the cerebrum; necrosis of a portion of the head and neck of the thigh-bone; extensive laceration of the liver, which the patient survived seven weeks, 120
Hydatid abscess of the liver, opening into the right pleural cavity—great enlargement of the head, occasioned by a morbid growth from the cranial bones, 172
General softening of the brain, with abscess in the left cerebral hemisphere, in connexion with caries of the temporal bone; an example of a single kidney being found in the body; malformation of the pulmonary semilunar valves; cancer of the posterior mediastinum; two specimens of cystic oxide calculi, 197
Cholesteatomatous and cystic tumour of the ovary, 146
Ulcerated cancerous tumour of the right anterior arch of the fauces; hypertrophy of the spleen; crystals in substance of spleen (splenic murmur); ulceration of colon; suppurative peritonitis, causing perforation of the intestine and of the abdominal parietes, 250
Red and white softening of the right hemisphere of the brain; perforation of the intestine in a case of typhoid fever, 454

Philomathic Society of Paris:—
On goitre and cretinism, 278

Royal Medical and Chirurgical Society:—
Remarkable case of foreign bodies in the stomach and duodenum, complete obstruction of the bowels, and mechanical displacement of organs; aneurism by anastomosis in the orbit; ligature of the common carotid artery, 94
An abstract of five hundred and eighty-three *post-mortem* examinations of the uterine organs, 140
Case of scirrhus of the rectum; cases of intestinal obstruction, 248
Anniversary Address by the President, 274
Case of stricture of the colon, successfully treated by operation after thirty days' obstruction, 302
Vaccination tested by the experience of half a century, 328
Case of inversion of the uterus after parturition, proving fatal in eighteen months, 378
A few remarks on the surgical operations usually adopted for retention of urine, 450
On fibrinous deposits on the lining membrane of veins; remarks on hydrophobia, 503
A case of hæmorrhage from inversion of the uterus; on the occasional organic union of contiguous teeth, 551
On some of the principal effects resulting from the detachment of fibrinous deposits from the interior of the heart, and their mixture with the circulating blood, 601

Statistical Society of London:
Mortality among medical men; sickness and mortality of the troops (European and native), under the Government of Bombay, 505
